

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Medical

Some Observations

CONCERNING WHAT IS CALLED

NEURASTHENIA.

By SIR A. CLARK, BART., M.D., LL.D., F.R.S.,
PHYSICIAN TO THE LONDON HOSPITAL.

WINNING its way in the face of a just but feeble opposition to general acceptance, the term Neurasthenia is at last to be found heading a chapter in almost every one of our systematic and clinical works. The state or assemblage of related and unrelated symptoms to which this name is given has been more or less fully recognised and described by every competent observer and writer from the days of Cheyne and Whytt until now; and in general works or in special monographs under such designations as the English malady, mimosis inquieta, the nervous state, nervous erethism, and others mentioned below,[1] there are to be found descriptions of it as clear, comprehensive, accurate, and distinctive as any that occur in the work of Dr. Beard on American Nervousness and Neurasthenia. For what good purpose, then, this term has been proposed, accepted, and employed I am unable to discover; and regarding it as at once vicious, inaccurate, and therapeutically misleading, I purpose submitting it to a brief critical examination.

The word "neurasthenia" means, on the face of it, nervous exhaustion; and applied to a certain assemblage and progression of symptoms, it further means that the whole and sole cause of them is to be found in this alleged exhaustion. Now this theory may be accurate or inaccurate; it may be good or bad; it may help or it may hinder the growth and use of knowledge; but in any case the employment of it in naming, and the introduction of it into a term whereby a given group of phenomena is hereafter to be known, violates a fundamental canon in the framing of a scientific nomenclature, and is, in the order of science, an unpardonable sin. For, however some may boast, there is not yet before us conclusive historical evidence of the finality of any theories. The highest, widest, and best of them are soon refuted, displaced, absorbed. Incorporated into terms applied to permanently recurring phenomena, they continue to suggest explanations when they have long ceased to have their place and use; they beget confusion; they originate and disseminate error; they make difficult, and at length impossible, the profitable discussion of ideas; and they do not merely hinder, they also throw back, the progress of true knowledge. It becomes, therefore, the plain and paramount duty of every observer and writer proceeding to name a distinctive group of closely related phenomena to avoid, in the naming, hypothetical explanations, and out of one or more of its exclusively physical qualities to frame the term by which the group is for the future to be known. In naming after this rule, the name given will remain, whilst the theories of the thing named will pass away; and thus, whilst keeping clear the various avenues to knowledge, and making plain the ideas requiring to be discussed, we shall also be giving loyal obedience to one of the supreme commandments of science. But the term "neurasthenia" as now employed is vicious not only in its scientific but likewise in its clinical relations, and it has multiplied the errors inseparable from the imperfect knowledge of earlier writers. It is in its nature defined to be an "impoverishment of nerve force resulting from imperfect metamorphosis of nerve tissue," and elsewhere as "deficient quantity and impaired quality of nerve force."[2] Now, setting aside questions of quality, for variations of which we have as yet no certain criteria, it is not to be doubted that such a state of "nervous debility" does exist; it is not to be doubted that when existing it will make itself manifest by more or less characteristic symptoms; and it cannot be denied that if those symptoms, due exclusively to mere defects of nerve force, were critically selected and arranged, they would constitute a group of nerve symptoms to which the term "neurasthenia" might be fairly, but, according to our canon, unscientifically applied. This, however, is exactly what has not been done, and what there is at present, I fear, small prospect that anyone will do.

When the symptoms set forth as characteristic of neurasthenia are carefully examined, it will be seen that they constitute an assemblage of incoherent indications of disorder borrowed more or less freely from inchoate forms of insanity, and from almost every disease of the nervous system; that they are not characteristic of any definite disorder; that divisions of them belong to disorders the most diverse; that no common law of treatment can be safely applied to them; and that, published with some parade as coherent and conclusive evidences of a state of "nervous debility," they exhibit defects of observing, reflecting, and critical powers unpardonable in those who court or claim the attention of the profession. But hidden within the signs described as characteristic of neurasthenia, and concealed under such terms as astraphobia, topophobia, agorophobia, claustrophobia, anthropophobia, monophobia, photophobia, mysophobia, pantophobia, and the like, there are symptoms, various but related, which anyone with sufficient experience and competent faculties of observation and critical analysis can easily discover, arrange into a well-defined group, and present to clinical medicine under the justifiable name of mere and shere nervousness. All persons exhibiting this group of symptoms have a tolerably uniform natural history, possess what is understood as the nervous temperament, and are said by members of our profession, as well as by the general public, to be sufferers from nervous debility. But it is more than doubtful if weakness, used in its ordinary meaning, is the sole or the chief characteristic of sufferers from nervousness. For the most part they present the appearances of health. Always excitable and sometimes depressed, they are often animated and joyous; procrastinating, fragmentary, and inconstant, there are, nevertheless, to be found among them the greatest workers of the times; talking occasionally for hours without fatigue, they are sometimes silent and grave; for the most part fastidious, refined, and cultivated, they fall occasionally under the dominion of sensuousness and the lower emotions; habitually tormented by a physical self-consciousness, they can yet efface themselves in their devotion to others; disposed to the flesh and the world, they often attain the greatest heights of the spiritual life; always ailing, they are seldom ill; often condemned to premature death, they live, as a rule, long beyond the average duration of life; and regarded by the hard, stolid, and superficial with feelings akin to contempt, it is nevertheless from them, far more than from any other class of persons, healthy or disordered, that we get all that is truest and highest, best and noblest, in science or letters, in art or song.

Such are some of the more prominent external characteristics of sufferers from nervousness. What the intimate nature of it may be, the present conditions and limitations of knowledge do not permit us to know; but I think myself on safe ground when I say that it cannot be a mere weakness of the nervous system.

If we engage in a critical study of the symptoms of nervousness with the view of coming to a nearer and clearer understanding than we now have of its nature, we must inquire into its internal characteristics and endeavour to discover among them what may be called the proximate constituents of that state of which nervousness is the main external expression. I say here, of set purpose, "the main external expression"; for doubtless the state expressing itself in nervousness has—through nutrition, secretion, and many dynamic conditions—manifold expressions of its presence which are neither comprehended nor considered among its ordinary symptoms. It is not within the scope or purpose of these remarks to supply an exhaustive and accurate statement of the proximate conditions of nervousness; but in order to make plain my meaning of at least one of the things needed for the further elucidation of this subject, I shall set down, just as they occur to me, the chief dynamic nerve states which, combined in various ways and degrees at different times, give rise to the symptoms of nervousness:—

1. A too rapid production and expenditure, together with an irregular distribution, of nerve force.

2. An abnormal sensitiveness and freedom of communica-

[1] In the second edition of Axenfeld the following terms are given as synonyms of neurasthenia: Cachexie nerveuse; maux de nerfs; diathèse nerveuse; marasme nerveuse; vapeurs; surexcitation nerveuse; nevrose proteiforme; faiblesse irritable du syatême nerveux; fièvre nerveuse; hyperthésie générale; neuralgie générale; neuropathie aiguë cérébro-pneumogastrique; nervosite neuroespasmie; nervosisme; état nerveux; maladie nerveuse. [2] Beard.

Digitized by Google

tion throughout the whole nervous system, but chiefly in the basal ganglia, and in the parts below them.

3. An unstable equilibrium of the whole nervous system, especially excessive in the vaso-motor centres, whereby are brought about, in nervousness, the flushings, blushings, and pallor of tissues and organs.

4. Disturbances of the general regulatory or special inhibitory powers, arising, independently of localised nerve-centres, through mere augmentation, defect, or interference with each other of automatic or reflex nerve-discharges.

5. A recurring state of more or less intense physical self-consciousness, through which there come within the cognisance of the organism certain of its own states, disorders, and actions, which lie far beyond the ordinary area of the consciousness of average persons.

I have alleged that this term "neurasthenia" is therapeutically misleading, and I shall now endeavour to make good the allegation. If it be true—and, for my part, doubt is impossible—that under the term "neurasthenia" no clear, definite, and distinctive account is given of true nervous exhaustion; that the descriptions of neurasthenia, as written in books, are composed of symptoms of the most diverse diseases and disorders artificially framed into an incoherent whole; and that in this heterogeneous mob of symptoms we can discover at least one group, not mainly asthenic, but the reverse, sufficiently distinctive in its characters, course, and issues to warrant the bestowal of a separate name,—then there is no further need of argument to show that for such an assemblage of symptoms no single method of treatment can be rationally designed or even safely applied.

In the treatment of dynamic nerve disorders two great plans of treatment are pursued. The one consists of change of surroundings, separation from friends, abundant feeding, rest in bed, and massage; the other consists essentially in discontinuance of business, generous living, distraction, and travel. Each plan has its own group of suitable cases, and each can boast of its own successes, often brilliant, although often temporary. But there is one group of cases, the cases of mere and sheer nervousness, to which, in general, neither of these plans can be successfully or safely applied. One or the other failing, and too long followed, brings about on occasions, frequent enough to demand serious consideration, mental and moral disasters which are now and then irreparable.

In cases of mere nervousness unaccompanied by any conclusive objective evidence of weakness, the plan of treatment which empirical experience has shown to be the safest and the most successful differs widely from the other plans, is difficult to follow, and provokes the antagonism of the patient's friends, who are usually constrained by some fatal necessity to destroy those whom they love. It consists in placing the patient in the physiological conditions most favourable to the general health; in a simple but liberal mixed dietary, arranged in three daily meals; in an extremely moderate use of, or abstinence from, tea, coffee, tobacco, and alcohol; in cold or tepid sponging and warm clothing; in promoting without unduly stimulating the excretory organs; in full, regular daily purposive necessary work; in self-effacement and the repression of every form of physical self-consciousness; in cultivating the exercise and control of the will; and in encouraging, or even urging, the patient to do with his might and without fear whatsoever has fallen to his hand to do. By the following of some such plan as this, difficult and painful at first, but easy and pleasant at last, the sufferings of nervousness will be in most cases removed, and the sufferers, by their discipline, will be lifted to a higher level of physical and moral life.

Returning to my immediate purpose, I sum up these observations in saying that the term "neurasthenia" is unscientific, inaccurate, and misleading; that the descriptions given of it do not include a clear, concise, or distinctive account of genuine nerve exhaustion, and do include a mob of incoherent symptoms borrowed from the most diverse disorders; that for a malady thus constituted and containing antagonistic conditions, no rational principles of treatment are possible; that in the heterogeneous assemblage of disordered states ascribed to neurasthenia, there may be discovered a group of coherent and distinctive symptoms arising out of mere and sheer nervousness; that the general treatment proposed for neurasthenia and applied to this group of cases would prove probably unsuccessful and possibly disastrous; and that for the purely nervous cases as I have described them the most successful treatment, and also the highest, consists of diet and discipline, work and will. For even a delicate organism, the fullest regulated discharge of all its functions is the cardinal condition of its highest life.

ABSTRACT OF A

Clinical Lecture

ON

EXCISION OF THE KNEE-JOINT.

By A. F. McGILL, F.R.C.S.,

PROFESSOR OF ANATOMY IN THE YORKSHIRE COLLEGE, SURGEON TO THE LEEDS GENERAL INFIRMARY.

THE operation of excision of the knee is one which has only been recognised as a legitimate surgical procedure in comparatively recent years. Indeed, at the present time there are surgeons who object to it and do not practise it. It was performed for the first time a hundred years ago, but was entirely neglected till revived by Fergusson and Syme. The results at first obtained were not highly satisfactory, and the operation was condemned by many of the leaders of the profession. The fact that it was condemned by many distinguished members of the surgical world would naturally be very satisfactory to those who introduced it; for it is a remarkable fact that few notable improvements are introduced into surgical procedure without meeting with violent opposition from many of the most distinguished among us. Examples of this are not far to seek. The introduction of the ligature by Paré as a means of arresting hæmorrhage, in place of the barbarous cautery iron or boiling oil, was condemned by his more distinguished *confrères*, and was not generally practised till many years after his death. It might, however, be supposed that things are better now than in the sixteenth century, but we find the same thing still going on. The introducers of ovariotomy were threatened with prosecution for manslaughter, and yet the operation is one of the most successful practised in surgery. Antiseptic surgery has revolutionised surgery and has saved innumerable lives, and yet many surgeons now living objected to its introduction and derided the principles on which it rests; and within the last year one of the leading metropolitan Medical Societies has excluded from its Transactions a most valuable paper advocating the adoption of a new plan of treatment for uterine fibroma by means of an operation which gives every promise of success.

It is usual to consider excision of the knee from two points of view—the mortality which accompanies it, and the utility of the resulting limb. Though at one time it was seriously argued that the limb with an excised knee was in no way superior to an artificial or peg-leg fitted on to the stump of an amputated thigh, it is now unnecessary to discuss this subject. We have all had many opportunities of seeing patients with excised knees walking with a scarcely perceptible limp, the necessary ankylosis being the only respect in which the one leg was inferior to the other. We may therefore dismiss this part of the subject, and proceed to consider the mortality and danger of the operation. Statistics show that in its early days the death-rate after excision of the knee was far from satisfactory. Swain in 1869, collected particulars of 472 cases, and found that 116 died, a death-rate of 24·5 per cent. But it must be recollected that at that time all operative results were inferior to those met with at the present time. Since the new Leeds Infirmary was opened, in 1869, the operation has been performed 116 times. In the old infirmary ten cases only are recorded, with one death; but of the remaining nine two were amputations. Of the 116 cases eight died, a mortality of 6·9 per cent. This result is good, but if we take the last five years from the beginning of 1881 to the present time, we find there have been sixty-three cases with only two deaths, a mortality of only 3 per cent. One of the fatal cases occurred in a man who died at the end of a month from acute inflammation supervening in lungs already diseased, and containing small cavities of long standing; in this case the excision wound was almost healed. The other died of septicæmia, but the case was not

Digitized by Google

an ordinary one, as the operation was performed for compound fracture into the knee-joint some time after the receipt of the injury; his general condition was unsatisfactory when the operation was performed; he did not improve after it; amputation was then resorted to, and death was the result. It might fairly be argued that in neither of these cases could death be fairly attributed to the operation, and we should then have sixty-one successive successful cases. But reckoning the mortality at 3 per cent., the result must be considered extremely satisfactory. It is only fair, however, to add that 10 per cent. of the cases failed as far as preservation of the limb was concerned; the limbs in these were amputated; but, with the exception of the case mentioned above, the second operation was successful in every instance.

[After describing the various methods which had been adopted in the performance of the operation, the lecturer proceeded to summarise the various steps of the operation, as follows.]

1. The incision is best made in a straight line from the posterior border of one condyle to a corresponding point on the opposite side over the centre of the patella, the joint being opened by dividing the bone with the saw, and removing the two portions separately. The advantages of this incision are that it enables the superior cul-de-sac of the synovial cavity to be thoroughly explored, that it facilitates the firm fixture of the limb on a splint, and that it makes the skin wound as small as possible. 2. The section of the bones must be made so that they will accurately fit when brought into apposition. This is best done by holding first the thigh and then the leg in a vertical position, exactly at right angles to the operation table, the saw being applied horizontally. It is found much easier to make the sections in this position than to hold the limb obliquely and trust to the eye for direction. 3. The whole of the diseased structures must be removed—all diseased pulpy synovial membrane by excision or scraping, all granulation tissue in sinuses by scraping, and all diseased bone with the gouge. It is specially needful that the superior cul-de-sac of the synovial pouch be thoroughly explored, as if this is not done secondary abscesses not unfrequently form in this position and give rise to much trouble. The thorough performance of this step of the operation is absolutely necessary if union by the first intention is desired. 4. The femur and tibia are sutured together, holes are made with a gimlet on each side of both bones, and a double thickness of No. 3 catgut passed through them and firmly tied. The catgut answers as well as wire, and does not require to be removed. 5. A drainage-tube is inserted on each side of the wound and brought out at the angles of the wound, or, if necessary, at more dependant openings specially made. Sutures are inserted to bring the edges of the skin wound into apposition, and the wound, being thoroughly irrigated with a 1·05 per cent. solution of corrosive sublimate, is dressed with dry antiseptic dressing. At the Leeds Infirmary salicylic silk or cotton-wool, and a large amount of iodoform, are generally adopted for this purpose.

The operation being thus completed, it is necessary to apply a splint, so that perfect rest may be ensured. Large numbers of appliances have been used for this purpose, many of them—as, for example, Fergusson's excision splint—being heavy and unwieldy. It is well to remember that it is always better to apply a splint to a limb than to apply the limb to a splint. In other words, the lighter the splint the better. In these cases nothing answers better than a piece of Gooch's splinting, cut out to fit the limb, and extending from the trochanter to the ankle. This, firmly applied with [illegible] down the thigh and up the leg to within an inch and a half or two inches of the wound, keeps the limb in perfect rest, and enables the patient to be moved, or, after a few days, to move himself about in bed without difficulty or discomfort. A large pad of [illegible] dressing being applied over all, the first dressing is complete. The question when the first dressing should [illegible] is next discussed. Should the limb be disturbed on the fourth or fifth day, and the dressings changed, and the drainage-tubes removed? or is it better to delay the first dressing for three weeks or a month? Cases were quoted [illegible] either proceeding may yield satisfactory [illegible] patients lately under treatment had not been [illegible] more than three weeks, and their wounds were [illegible] when the next dressing was applied three [illegible] in two other cases a thorough change, necessitated by the copiousness of the discharges, was made on the fourth day; in these cases also complete union was established without further change. We must be guided by the amount of discharge and the condition of the temperature, but in the majority of cases one early dressing seems to be advantageous, making the patient more comfortable and diminishing the risk of septic infection of the wound.

As regards the treatment of any particular case there are four courses open to us—non-operative treatment, erasion or arthrectomy, excision, and amputation. Amputation is required when the general condition of the patient is such as to render any minor proceeding inadmissible, when the patient is suffering from some organic lesion distinct from the local affection, or when, owing to the local affection, the temperature is much elevated. We are also occasionally driven to amputation in cases where there is extensive disease of the bones accompanying the joint mischief, or when the tibia is so far dislocated as to render it impossible to restore the limb to a straight position. The question between excision and time can only be answered by considering the various peculiarities of each individual case. It is generally stated that excision is a procedure more adapted for poor hospital patients than their richer brethren. It is no doubt true that many cases of joint disease, if favourably situated, will after months, or more frequently years, recover with a stiff limb, but even then they are no better off than the patient with the excised joint, who has recovered in a comparatively short time. In all cases, when, after a few months' treatment by the usual methods, no signs of amendment appear, operation should be recommended. The only question is whether the operation should be excision or erasion. Experience of the last operation on a large scale is as yet wanting, but it seems not improbable that in a few years many cases which are now excised will be erased, and that patients thus treated will recover with a slightly movable joint. Fortunately, the first step of the operation is the same in both cases, consequently the surgeon need not determine which procedure he will adopt until he has carefully examined the condition of the various tissues which form the joint. Should the disease be extensive, he will excise; should it be more limited and chiefly confined to the synovial membrane, he will erase. In this latter case the two fragments of the patella must be united by suture.

ABSTRACTS OF THE

Brown Lectures,

DELIVERED AT THE

UNIVERSITY OF LONDON,

BY VICTOR HORSLEY, M.B., B.S., F.R.C.S.,

PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTE, ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

RELATION OF THE THYROID GLAND TO GENERAL NUTRITION.

THE essential cause of myxœdema and cretinism had been shown last year by Horsley to be loss of the thyroid gland. He assigns the following functions to the thyroid gland: (1) regulation of the metabolism of mucinoid albumen by restoring certain waste products; (2) hæmapoiesis. The latter function is probably dependent on the presence of tissue like that contained in the spleen; the occurrence of anæmia after removal of the thyroid gland is sufficient proof of the hæmapoietic function. Examination of the blood from the superior thyroid artery and corresponding vein also showed that the vein contained 7 per cent. more red blood-corpuscles than the artery. The symptoms that follow removal of the thyroid body were discussed in three stages. The first, a *neurotic* stage, was characterised by the occurrence of a constant tremor having a definite rate of eight per second. To this constant tremor were subsequently added paroxysmal convulsions, contracture, and functional paralysis. Apparently young animals do not survive this stage, but succumb from failure of the cardiac and respiratory centres in the medulla oblongata. The duration of the first stage was variable; in dogs it lasted

Digitized by Google

generally a week, in monkeys from two to three weeks. The second or *mucinoid* stage is marked by the deposition of mucin in the tissues and blood. The mental symptoms continue into this stage, the animals becoming imbecile, but the motor symptoms usually cease. This stage was only seen in perfection in monkeys. Since last year Mr. Horsley has found a most important determining factor in the survival of thyroidectomy by adult animals, and that is the employment of heat. By keeping the animals at an artificial high temperature Mr. Horsley has succeeded in prolonging the existence of the monkeys. With longer life they, however, become emaciated, losing their excess of mucin, and ultimately die of general failure, especially of the lower visceral centres. The third stage is therefore termed the *atrophic* or *marasmic* period. It is in a similar way that cretins appear to die if not carried off by some intercurrent disorder. This novel prolongation of life gives a close resemblance to cretinism. An autopsy by Bruno of a case of cachexia strumipriva failed to reveal any sign of mucoid degeneration, and Mr. Horsley suggests that this case had lived through the mucinoid period. In this connexion it is also well to remember that in some cases of myxœdema no great excess of mucin is found in the tissues after death.

Recognising to the full, as the lecturer does, the important part that the thyroid gland plays in the metabolism of the body, he adduces strong arguments to show that the symptoms of mere senility may be accounted for by loss of the functions of the thyroid body. Some men, he suggests, enjoy a "green" old age because their thyroid glands are in good working order. This suggestion is led up to by the fact that age exercises a great influence on the occurrence of symptoms after the removal of the thyroid body. In old dogs, removal merely leads to indolence and incapacity; whereas at the other extreme of life removal causes symptoms of violent sort, often terminating in rapid death. Age, therefore, is of the utmost importance. In old age the thyroid gland degenerates, there is an overgrowth of connective tissue, with fatty and pigmentary degeneration of the epithelia, and concentration with pigmentatory alteration of the contents of the vesicles. In myxœdema, Mr. Horsley states that there is a rapidly progressing form of the same atrophic cirrhosis that more gradually obliterates the glandular tissue in old age. As the question is almost purely one of loss of nutrition, it is plain that the previous state of nutrition as well as age must have some share in the production of symptoms. Cold, which has a marked depressant action in nutrition, takes a prominent place in the development of symptoms after the removal of the thyroid gland. Starvation and previous illnesses, and other like causes, damaging the general health and nutrition, must also be taken into consideration. As to the cause of the cirrhosis of the thyroid gland we know nothing, except the suggestion of Dr. Hughlings Jackson that it is dependent on disease of nerve nuclei of the floor of the fourth ventricle.

During the past year animals have been kept after operation at an average temperature of 90° F., and directly symptoms appeared the animal was put into a hot-air bath at a temperature of 105° F. The results of these experiments are very striking. The animals in this new series survive the operation four, five, and six months, whereas before they only lived as many weeks. Next to this increased longevity thus attained, the most noteworthy fact is the suppression of the leading symptoms of the first two stages, and especially of the first. The interval that elapses between the operation and the appearance of the first symptom was also increased; in the former series it was four days, and in the new series it was ten or more days. The beneficial effect of the hot-air bath in myxœdema is due to the influence of warmth in maintaining nutrition, and not to any action on the cutaneous secretions. The precise *modus operandi* of heat is a point for discussion. Mr. Horsley suggests that it spares the forces of the organism by preventing excessive loss; it is simply a saving of heat. In animals kept at a high temperature the mucous glands and parotid glands do not take on excessive action, this being the opposite of what was observed last year; a proof that the action of the heat is to modify powerfully the nature of the degenerative metabolic processes. Anæmia and wasting are the chief symptoms observed in the cases of artificial myxœdema treated by heat. The most delicate tissues feel the metabolic derangement most severely, and so rapid degeneration of the cells of the anterior horns of the spinal cord is observed; it was seen chiefly in the outer groups of cells. All stages of degeneration of the corpuscles could be traced. It is probable that the tissues of the female are more predisposed to degenerative errors of metabolism than those of the male. The relation of the thyroid gland to the uterus is witnessed during the catamenia and during pregnancy; this increased excitability probably renders it more liable to disease. Hence the greater liability of women to suffer from myxœdema.

Classification of the Symptoms that follow Loss of the Function of the Thyroid Gland.

Stages.	Duration.	Symptoms.	Remarks.
I. Neurotic.	One to two weeks in dogs; one to three weeks in monkeys.	Tremors, rigidity, dyspnœa.	Young dogs and monkeys alike die in this stage.
II. Mucinoid.	Half to one week in dogs; three to seven weeks in monkeys.	Commencing hebetude and mucinoid degeneration of connective tissues.	Dogs survive only to the beginning of this stage; monkeys die at the end, if not treated.
III. Atrophic.	Five to eight weeks in monkeys.	Complete imbecility and atrophy of all tissues, especially muscles.	Monkeys survive according to the temperature of the air-bath.

LECTURE II.

MODERN PATHOLOGY OF THE CENTRAL NERVOUS SYSTEM.

The "motor" region of the cortex is connected with other parts of the cortex by commissural fibres. Mérique has divided these without injuring the pyramidal tracts; the cortical centres thus isolated remained inactive for the reason that they received no afferent impulses to transmute into efferent energy. Schiff has taught that the posterior columns of the spinal cord are conductors of tactile sensation direct to the excitable area in the cortex; but Mr. Horsley shows that the results obtained by Schiff are to be explained by the injury that is unavoidably done to the motor tracts in the spinal cord. In other words, section of one posterior column does not by itself produce complete ataxia, does not produce the paretic position of the foot described by Schiff, and does not produce tactile anæsthesia of the same side. The view of Schiff and Munk that the so-called "motor" area is in reality a sensory one is therefore not supported by experiments, of which the results have been above given.

The fundamental rate of nervous discharge in nerve-centres, the mode of discharge from stimulated cortical motor centres, and the nature of the muscular contractions that follow stimulation of the cortex, corona radiata, and spinal cord were the next three subjects under discussion. In stimulation of the cortical centre of the muscle the following facts are observed: 1. A period of latency of varying length. 2. Tetanus followed by relaxation when the stimulus is shut off. There may also be seen with greater or less distinctness waves on the tetanic curve and further similar waves on the line of descent, and finally clonic spasms of gradually diminishing rate but increasing amplitude follow the tetanic stage; in fact, from the normal cortex it is possible to excite a typical epileptic seizure.

A more intense current is required to stimulate the exposed corona radiata so as to cause contraction in the muscle; the latent period is, however, shorter; the muscle rapidly passes into complete tetanic spasm, and the moment the current is shut off the lever falls to the base line. No epileptoid spasms follow, and it is exceedingly rare to observe any waves on the tetanic curve of the corona radiata.

The spinal cord is excitable and the curve obtained is somewhat like that obtained from the corona radiata. The uprise of the tetanic curve is, however, sharper and more rectangular; the level of the curve is better maintained and the fall is very sharp and sudden. Small waves are occasionally to be seen on the tetanic curve, but it is extremely rare ever to see anything resembling epilepsy. The wave rate of the tetanus resulting from stimulation of the peripheral end of a cut nerve exactly corresponds to the rate of interruption of the stimulus.

The tetanus from cortical stimulation is due to a fusion of discharges which are grouped together at intervals of twelve to thirteen per second; but frequently it is found that the rate of these discharges is eight per second. The subsequent clonic spasms also have a rate of eight per

Digitized by Google

second at first, this becoming slower—four per second—as the result of fusion. Schäfer and Horsley regard the rate of eight to ten per second as the fundamental rate of discharge of motor cells in most mammalian animals. This is the rate given by Lovén from the spinal cord in strychnised frogs. A study of tremors resulting from disease leads Mr. Horsley to the same conclusion that the discharge from nerve centres proceeds at this constant rate, or some multiple or division of the same. In paralysis agitans, disseminated sclerosis, tremors of artificial myxœdema, and canine chorea, this law was found to hold good. Gowers some years ago showed that the rate of ankle-clonus was eight per second.

Dealing with the share that the motor corpuscles of the brain and those of the anterior horns take in the production of the tetanus and the other waves, Mr. Horsley suggests that the spinal motor corpuscles may become polarised, and merely act as transmitters of certain kinds of vibration originating in the cerebral motor cells. Schäfer and Horsley contend, in opposition to François Franck and Pitres, that, whatever be the rate of an adequate stimulus applied to the cortex, it causes the motor corpuscles to discharge at the fundamental rate of eight per second, or some multiple of it. The view of Franck and Pitres would reduce the cortical motor centres to the level of simple conductors. It is important to observe that stimulations from the cortex, corona radiata, cord, and nerve give very different modes of tetanic spasm. Experiment proves in Mr. Horsley's hands that the motor tract of the spinal cord is irritable to the interrupted current, for contraction of all the muscles on the *same* side followed stimulation of the lateral tract. This fact militates against the idea of intimate commissural union between motor centres in opposite sides of the spinal cord. Tracings from a case of traumatic epilepsy closely resembled those taken from experimental stimulation of cortical centres, affording further confirmation of the professor's view. He thinks that if a tracing from a muscle shows sustained tetanus, with a gradual fall and marked along its whole course by small waves, and finally followed by waves indicative of clonic spasms, the diagnosis of cortical discharge should be irrefutable. The fundamental feature of this lecture is the importance that he attaches to the different tracings obtained by stimulation of different parts of the motor tract. The tracing from cortical stimulation is, so to speak, pathognomonic, and cannot be confounded with that obtained from other parts of the motor path.

LECTURE III.

EMOTIONAL NERVOUS DISORDERS DUE TO LOSS OF THYROID GLAND AND PITUITARY BODY.

Disorder in the nutrition is the first event that happens in "functional" nervous disorders. In artificial myxœdema, tremors, clonic spasms, and paralysis were to be observed in this definite order, and constituting the stages of a typical progress of functional "dissolution." It had been shown in the first lecture that the hiatus produced in the continuous chain of metabolic processes caused by the loss of the thyroid started an increasingly defective state of nutrition, and that the motor nerve corpuscles were almost the first tissues in the body to evidence the defect. Mr. Horsley prefers also to invoke the aid of loss of inhibition to account for the occurrence of tremors or their nervous equivalent—rhythmical discharges. He, moreover, does not incline to the view that mere defect of nutrition leads to rhythmical action in nervous centres. He holds that each discharge is the result of actual irritation, in the form of ordinary constantly occurring stimuli. As confirmatory of his view he remarks that slight lowering of the external temperature increases the tremors or induces them. Tremors due to alcohol, mercury, and those occurring during convalescence, are also regarded as illustrations of his view, as well as confirmatory of the law of the rate of discharge from motor centres. Paralysis agitans and the tremor of senility have each the same rate of eight to ten per second. With Hughlings Jackson, Mr. Horsley thinks the cause of paralysis agitans should be looked for as the result of direct interference with general nutrition—i.e., of the centres governing general nutrition. This interference may be produced by disease of the apparatus of metabolism, or, as at first suggested, by trophic changes in the muscles themselves. Emotion may damage the nerve centres, in which the causation of paralysis agitans [illegible] may be regarded as an example. Removal of the thyroid gland means injury of the apparatus of metabolism. The lecturer next describes the results of stimulating the nerve centres, whose nutrition has been depressed by loss of the thyroid gland.

The curve of tetanus caused by stimulation of the normal cortex being borne in mind, that resulting from stimulation of the cortex of a dog suffering from the tremors of artificial myxœdema differs in the fact that the curve of tetanus drops immediately the stimulation ceases; in fact, the end of the tracing closely simulates that obtained from the cut corona radiata. The clonic spasms that marked the curve obtained from the normal cortex were very imperfectly marked, and altogether irregular. The first effect of stimulation of the cortex is to produce in the neurotic stage of artificial myxœdema a condition of hyper-excitability followed by rapid exhaustion. Stimulation of the other parts of the pyramidal tract evoke nothing of any importance, unless it be signs of rapid exhaustion. The tremors can be suppressed alike by stimulation of the cortex and of the corona radiata. Stimulation of the divided spinal cord up to the point of fatigue was practised in the hope that the rate of discharge of the spinal cord might be obtained; this turned out to be possible, for after the disappearance of the primary tetanus from fatigue the tonic fusion of course ceased, and so allowed the individual discharges from the spinal centres to come out; the wave rate of these discharges was found, as expected, to be from eight to ten per second. Mr. Horsley regards this fact as of great importance as a means of diagnosis. The same results are obtained from the dog as from the monkey. In patients suffering from myxœdema, the sluggishness of the movements is due to the affection of the nerve centres, and especially those of the cortex, for the delay in the latent period which was observed in the experimental stimulation is especially a feature of the curve obtained from the cortex; those from the spinal cord and muscle being fairly normal in this respect. The loss of energy therefore affects chiefly the cortical centres. The gradual loss of nutrition resulting from removal of the thyroid body shows itself, first, by diminishing the power of the cortical centre in maintaining the tetanic character of the movement it generates; and, secondly, by the gradual abolition of the tendency to epileptoid seizures. The final stage is apparently one of complete loss of function of the central nervous system as far as movement is concerned. Mr. Horsley points out that we cannot have a more illustrative example of disorder leading to total loss of function, due in this case to general disturbance of the whole metabolism of the body.

The pituitary body has resemblances to and relations with the thyroid body. Mr. Horsley has removed this structure twice successfully; the animals (dogs) lived five and six months respectively. During life no nervous or other symptoms were noticed. Experimental stimulation of the cortex of the brain showed in both the dogs that there was a great increase in the excitability of the motor region. Stimulation with a fairly moderate strength of faradaic current gave an enormous tetanus, followed by severe and prolonged epilepsy or clonic spasms, fully as long and as severe as he has ever seen in the traumatic epilepsy of man, and far more severe than he has ever seen from stimulation of the normal cortex, or from the cortex in cases where the thyroid gland has been removed.

It seems clear that the greater the dissolution the quicker is the rate of the rhythm. He observed a tetanus of the rectus femoris in a case of traumatic epilepsy to have a rate of twenty-four per second, and this rate is but rarely obtained; but it existed in the two dogs from whom the pituitary body had been removed. In the same dogs, if the stimulus to the cortex were kept up for a quarter of a minute, clonic spasms were found to appear on the falling curve of the tetanus. A further point noticed was the termination of epilepsy by the occurrence of one tremendous spasm, instead of a gradual dying out of the clonic spasms.

MEMORIAL TO THE LATE DR. LANCHESTER.—There has just been erected in the hall of the Croydon General Hospital a tablet to the memory of the late Dr. Lanchester. It consists of a latten brass tablet carved in bas-relief with a representation of the parable of the Good Samaritan, and bears the following inscription:—"This tablet is erected by members of the medical profession to perpetuate the memory of Henry Thomas Lanchester, M.D., F.R.G.S., Surgeon to the Hospital from its foundation—a highly-prized friend and a valued colleague, whose death, at the early age of 46 years, they deeply deplore. Born A.D. 1839. Died A.D. 1885."

A NOTE ON CERTAIN MODIFICATIONS OF THE

SUPRAPUBIC OPERATION FOR STONE OR TUMOUR OF THE BLADDER.

BY SIR HENRY THOMPSON, F.R.C.S.,
SURGEON EXTRAORDINARY TO HIS MAJESTY THE KING OF THE BELGIANS, LATE PROFESSOR OF SURGERY AND PATHOLOGY TO THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, CONSULTING SURGEON TO UNIVERSITY COLLEGE HOSPITAL, EMERITUS PROFESSOR OF CLINICAL SURGERY, ETC.

THERE is a modification of the suprapubic operation necessary when dealing with the female bladder, since it cannot, without very special apparatus, be permanently distended like that of the male. And the same condition occurs in that of the male also, if, after opening the urethra for the purpose of exploring the bladder for tumour, and finding one, it is deemed necessary immediately to operate above the pubes. This may happen when by means of the urethral opening it is discovered that the tumour is too large to be removed by the perineal route, or is so situated that it can be only safely attacked from above. In either case the distension of the rectum is to be fully made as usual; but as no fluid can be securely retained in the bladder in the circumstances described, the incision must be made on a director previously passed into the viscus. This director should be in the form of a well-curved hollow steel sound, with an open end, neatly closed by an olivary bulb attached to a strong stylet running through the instrument and capable of being fixed at the handle. Fig. 1 shows the sound, and Fig. 2 the stylet, with the bulbous end. At the extremity of the sound, a wide open slit, about three-quarters of an inch long, is made in the concave aspect. See Fig. 3, with the bulb in place. Fig. 4 shows the end of the instrument when the bulb is withdrawn.

FIG. 1.

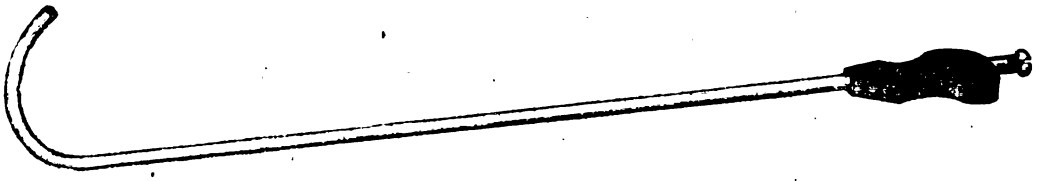

FIG. 2.

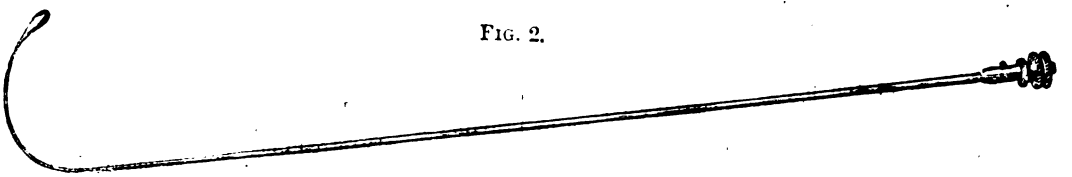

FIG 3.

FIG. 4.

The rectum being distended as before directed, no injection of the bladder takes place, but the sound containing the stylet is passed and retained in place by an assistant. The dissection is now carried on in the median line, as usual, until it has nearly reached the bladder, when the olivary end is plainly distinguished, and the stylet is withdrawn by the assistant. The end of the sound and the slit therein are now easily felt through the tissues by the index finger. When the fibres of the bladder are laid bare at and around this spot, the hook is passed deeply into the slit, so as to take up a portion of the vesical coat and hold it securely, while it is perforated by a scalpel in an adjacent spot. By this means the bladder is prevented from collapsing and slipping down out of sight or reach—an accident very apt to occur and to embarrass the operator if he opens the viscus on the end of an ordinary sound, which usually emerges by the opening, while the bladder disappears by contracting and shrinking around the instrument. In these circumstances it has often been found difficult to introduce anything into the cavity by the side of the sound, a dilemma which the little contrivance proposed above efficiently provides against. In the old method of operating on a staff, without distension of the rectum, this accident not infrequently happened, and I have little doubt that the endeavours to re-establish the route into the bladder sometimes occasioned disturbance of the cellular connexions around the neck, and so induced the infiltration there, formerly said to have been one of the risks of the operation.

Reverting to the use of the index finger-nail as a divider of tissue in the operation, and its marked superiority to the knife, it has occurred to me that a more generally applicable instrument might be constructed in ivory. Accordingly, Messrs. Weiss have made one to my design, of which the woodcuts Figs. 5 and 6 give a representation on a scale of exactly half the linear measurement. The lower, or slightly convex, end seen at Fig. 5 is very finely serrated, and acts as an artificial finger-nail; the hooked termination for drawing aside a vein is shown in a lateral view of the instrument at Fig. 6.

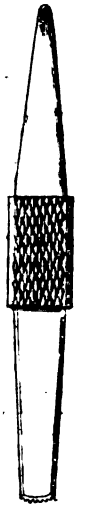

FIG. 6.

CONSEQUENCES OF NARROWING OF THE MITRAL VALVE WHEN OCCURRING IN CHILDHOOD.

BY SAMUEL WILKS, M.D., LL.D., F.R.S.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

IN the year 1844 my late colleague and teacher, Dr. G. H. Barlow, of Guy's Hospital, delivered the Gulstonian Lectures, having for their title "Diseases arising from Defective Expansion of the Lungs in Early Youth." The author illustrated this theme by examples of young persons who about the period of puberty exhibited symptoms of pulmonary obstruction, and often of dropsy, and in whom there was found after death a narrow chest, small lungs, a corresponding small trachea, and at the same time a heart diminished in size and the mitral orifice much contracted in calibre. He believed that if any cause existed which tended to contract the chest, pulmonary expansion would be impeded, the lungs would become small, and the mitral orifice, through which passed a diminished stream, would become proportionally contracted. There can be no doubt that a very interesting series of cases was observed by Dr. Barlow, but I have long thought that his reasoning about them was incorrect. His facts with reference to the relation between the organs of circulation and the attenuation of the body generally were no doubt true, and opened up a subject of great physiological interest, but I

Digitized by Google

am inclined to think that in the majority of such cases as he described the prime cause was not to be found in the contracted chest, but in the heart itself. A valve simply diminished in size is sometimes met with, but according to my own experience this is very rare, the contraction being usually accompanied by some indication of a previous inflammatory process. It is a curious fact that in very many cases there is a corresponding narrowing of the tricuspid valve. This might appear to prove that an endocarditis had undoubtedly at one time been present, although on the theory of adaptation the narrowing of the two valves at the same time would not be so remarkable. Two or three years ago Dr. B. Fenwick brought before the Pathological Society a large number of cases of stenosis of the tricuspid valve, and in nearly all of them the mitral was similarly contracted. The fact is one of great interest as showing the relation between the orifices of the two sides of the heart, for even if a rheumatic endocarditis had been the starting-point for the change, I cannot but think the determination of the size given to the softened and contracting valve was fixed by and was a measure of the amount of blood passing through it. Now since stenosis of the mitral is only occasionally accompanied by a corresponding narrowing of the tricuspid, but a contraction of the tricuspid is nearly always associated with a similar condition of the mitral, it may be fairly argued that the one is dependent on the other. The explanation appears easy, since in most instances of stenosis of the mitral the blood is thrown back on the lungs and right side of the heart, so that the latter becomes large and the orifices retain their natural size; whereas in primary obstruction of the tricuspid, which allows only a small quantity of blood to pass into the right ventricle and lungs, a diminished supply is sent to the left heart, and in this way its cavities, with its orifices, would become reduced in size. If this is possible, there seems no reason why a primary cause in the lungs which diminishes the amount of blood circulating in them should not produce the same effect, and by such an argument we see a justification of Dr. Barlow's theory. I might here remark that my experience accords with that of Dr. Fenwick, that in nearly all such cases of narrowing of the auriculo-ventricular valves, and more especially when it occurs on the right side, the subjects are women.

The object of the present communication is to draw more particular attention to the fact that if mitral contraction occur at a very early period of life, whether as a primary affection or secondary to a corresponding narrowing of the tricuspid, other parts of the circulatory system become accommodated to it, and that the patient may reach adult life before the narrowing shall have produced any symptoms; or, as sometimes happens, such contraction may be found accidentally after death without a history of any cardiac symptoms whatever. I saw lately a lady of forty-five years of age, suffering from cardiac dropsy, who informed me that a mitral bruit was known to exist as long as she could remember; and she had grown up conscious of it as part of her being. In various ways the effects of heart-disease are different as occurring in the growing child and adult. After a marked endocarditis in the child, resulting in thickening and narrowing of the mitral valve, there may be observed great enlargement of the left auricle, with hypertrophy of the right side, becoming sometimes so great as to cause bulging of the chest. In these cases the pulmonary artery partakes of the hypertrophy of the ventricle, and is often found thicker than the aorta. Many years ago, when demonstrating this condition, I used to teach that in all probability the second sound of the heart was produced more by the pulmonary than by the aortic sigmoid valves, and this was before I became aware of the clinical fact pointed out by Skoda that the second sound was more accentuated over the pulmonary orifice in mitral disease. But in cases where there has been no history of endocarditis, although it probably might at one time have been present, where the valves have become contracted without much thickening, and therefore retained their efficiency, these secondary effects do not and need not occur. It is evident that the whole of the blood of the body coming back to the lungs and then passing again to the left side, is measured by the size of the mitral orifice. If this be small, the blood passing through it is diminished in quantity, and it becomes a gauge of the reduced circulation. The left ventricle is therefore small, and the whole heart correspondingly diminished in size. The lungs are small as well as the chest, and the respiratory process correspondingly lowered, and with this probably the whole body is impoverished; at all events, the organism is working with a diminished amount of blood. I admit that these simple cases of narrowing are exceptional, for most frequently with the contraction there is some thickening which in course of years manifests itself by symptoms denoting an imperfection of the valve.

It is, however, the exceptional cases to which I wish to draw attention, those in which the mitral orifice, when narrowed, acts first by producing a diminished stream of blood, the amount in the system being measured by the small mitral orifice, and then, as before said, by a shrinking of other parts of the circulatory system. During the present year I have seen two such cases on the post-mortem table. One was that of a woman of middle age who had died of some long-standing disease of the brain. In her body was found a very small mitral aperture, admitting only the point of the finger, but having its edges pliable and in every way efficient as a valve. The ventricle was very small and the whole heart was diminished in size, proving that no obstruction or regurgitation had occurred at the mitral orifice. The lungs were not indurated, nor did they show in any way the congestive conditions so well known in heart disease where the blood has been impeded in its course, nor did the other organs display any indications whatever of analogous congestive processes. A very intelligent student expressed his surprise at the absence of the well-recognised conditions usually met with in obstructive mitral and other valvular diseases, and that there was not the slightest appearance in the body suggestive of stenosis of the valves of the heart. My answer to him was that there was no disease; the mitral orifice was smaller than natural, but an effective valve. The contraction had no doubt occurred at an early period of life, and so reduced the amount of blood, of which it was the gauge; that the whole heart became in consequence reduced in size, and an entirely new state of things set up. This condition is very different from what occurs when a person is full grown and becomes the subject of a stenosed mitral valve, but even then the prolongation of life is due probably in some measure to the reduced amount of blood in the system. This probably was the case in the example of the woman with dropsy before mentioned, who reached middle age before the condition arising in infancy produced any marked results. The fact is well known to all careful observers that a mitral bruit may exist for a great many years without the presence of any marked symptoms, and in such cases it is rightly said that the hypertrophy of the left auricle and enlargement of the right side compensate for the obstruction. This is no doubt true; but I wish also to show in this communication that in some cases the narrow mitral orifice cannot be looked upon in the light of disease; it has so modified the circulation in amount and caused all other parts of the system to conform to it, that a fair amount of health has existed during a lifetime. In such cases, in all probability, no bruit has existed, but merely an imperfect first sound.

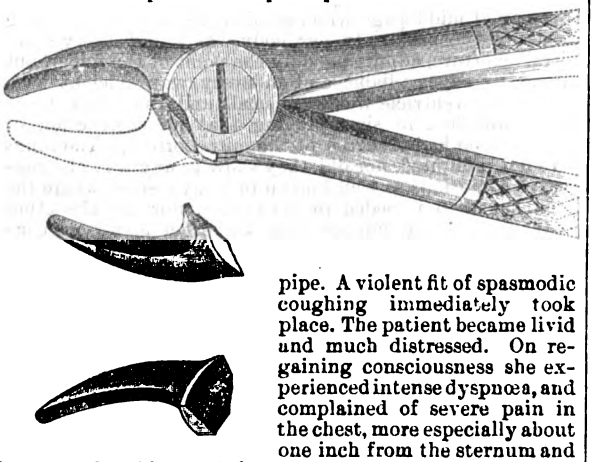
CASE OF

EXTRACTION OF THE BLADE OF A TOOTH-FORCEPS FROM THE RIGHT BRONCHUS.[1]

BY SIR WILLIAM MAC CORMAC.

PRISCILLA C——, aged twenty-four, a domestic servant residing at Barnstaple, was admitted on Nov. 23rd, 1885, into St. Thomas's Hospital, under the care of Sir William Mac Cormac. Seven weeks ago she determined to have several roots and teeth extracted previous to getting a new set of teeth. For this purpose chloroform was administered by Mr. Henry Jackson, of Barnstaple, on Oct. 13th, while she lay semi-recumbent upon a couch, the head being raised by pillows. Mr. Sanders, also of Barnstaple, extracted in succession the lower right wisdom tooth, five molar roots, one bicuspid root, and the upper right wisdom and upper right second molar teeth, ten pieces in all. A bicuspid forceps, one of Evrard's,[2] was then applied to the right upper second bicuspid tooth. Three outward and inward movements failed to shake the tooth, and the instrument

[1] From notes by Mr. W. F. Brook, dresser.



[2] Several dental surgeons who have seen the forceps are disposed to doubt that Evrard was the real maker, and from certain small differences in the forceps believe them to be a spurious imitation.

Digitized by Google

slipped slightly over the crown. It was readjusted, and again three times a lateral movement applied, always with downward pressure, when suddenly the palatine blade of the forceps broke short off at the thickest part of the shoulder-joint. At the same moment the patient made two or three deep inspirations, and on looking immediately into the mouth the bicuspid tooth was seen to be intact, while the broken portion of the instrument had disappeared. (Fig. 1.) It had passed through the glottis into the wind-

FIG. 1.

Bicuspid tooth forceps and portion broken off.

pipe. A violent fit of spasmodic coughing immediately took place. The patient became livid and much distressed. On regaining consciousness she experienced intense dyspnœa, and complained of severe pain in the chest, more especially about one inch from the sternum and between the third and fourth ribs. Several unsuccessful attempts were made, by inverting the patient and shaking her, to remove the piece of steel. An emetic was also given. Since the accident the patient has remained in bed, suffering from fits of coughing, accompanied by a good deal of pain, and thick, yellowish expectoration, occasionally streaked with blood. On two or three occasions she believes she distinctly felt the foreign body move, and the sputum afterwards contained blood. Once a small clot of blood was brought up. Three weeks ago she attempted to move about a little, but the pain and other symptoms became much worse, and she had to return to bed. The cough and dyspnœa have always been worse after any movement.

On admission, the patient complained of distressing spasmodic cough, pain in the right breast, especially after coughing, radiating to the right shoulder, down to the elbow, and up the right side of the neck; much dyspnœa, especially after coughing. Respiration is accompanied by general rhonchi. A rough, harsh, whistling sound can be heard both with expiration and inspiration, and this most distinctly over the right second intercostal space, just outside the sternum, and posteriorly on the right side on a level with the spine of the scapula. Râles are to be heard over the rest of the right lung; the left is comparatively free. Both sides of the chest move freely and there is no dulness.

Nov. 24th.—The patient woke up last night with an attack of dyspnœa, which lasted about ten minutes. There was no cyanosis. The expectoration is not abundant.

25th.—The patient has been much troubled with cough, which keeps her awake at night. She thinks the pain gets worse and the shoulder more painful. From the history and the tolerably clear evidence afforded on auscultation, Sir William Mac Cormac concluded that the broken blade of the tooth forceps was probably lodged in the right bronchus, and that there was no chance of its spontaneous evacuation. The plan of treatment decided upon was first to open the trachea very freely, and then to try to extract the piece of steel with forceps, the chief difficulty expected being that it would probably be found embedded in the wall of the tube, and from its smooth surface, with little to catch upon, would be difficult, perhaps impossible, to extract. A pair of strong polypus-forceps, slightly bent laterally near the extremity, was selected, as most likely to hold, being chosen from a number of others by trying which of them would hold best on a tooth-forceps blade.

Nov. 26th.—The patient being under chloroform, Sir Wm. Mac Cormac performed tracheotomy. The shoulders were well raised, and the head thrown back and steadied by an assistant. The incision through the skin extended from the cricoid cartilage nearly to the notch of the sternum and was about three inches and a quarter long. On dividing the skin and fascia, two large anterior jugular veins were seen. Cutting between these, the fascia stretching between the sterno-hyoid muscles was recognised and divided, and these muscles separated. The sterno-thyroid muscles were also pulled aside. There was but little difficulty in exposing the trachea below the thyroid body. Above the isthmus there were many veins, some of which bled when attempting to divide transversely the fascia from the upper margin

FIG. 2.

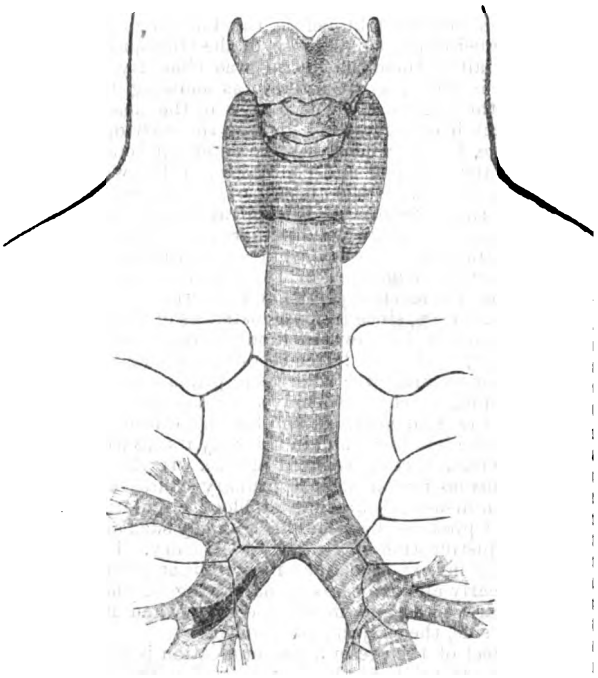


Diagram of the relations of the trachea in an adult female, half natural size, with the foreign body in the right bronchus, where it was believed to have become impacted.

of the thyroid. The trachea, therefore, was cleared in the lower part, and in order to give ample room it was decided to divide the thyroid isthmus. This was done by passing an aneurysm-needle, carrying a double silk thread, from below upwards, tying the tissue of the gland on each side and dividing between. It would have been otherwise impossible to manipulate the forceps, as was afterwards done. The isthmus of the thyroid was large, and covered three or four rings. As soon as it was divided the trachea became thoroughly exposed and accessible throughout its cervical portion. There was very little bleeding; several large veins had been seen and avoided, others clamped before division, and the wound was practically dry. A central incision was now made into the trachea from below upwards, an inch and a half long. Violent spasmodic coughing immediately ensued, but this failed to dislodge the forceps blade. A loop of silk thread having been introduced on each side into the margins of the tracheal incision, they could be widely drawn apart; the superficial soft parts were held aside by retractors, and it was possible to see some distance down the tube. The pair of forceps previously selected were then passed down the trachea; at first the blades were kept shut, and the instrument was used as a searcher. The septum at the bifurcation could be distinctly recognised, and the instrument passed on into the left bronchus, which felt empty. By reason of its curved extremity the forceps could be also readily passed into the right bronchus, and there it seemed to strike against the foreign body. At first the sensation was not distinct, the blade of the tooth-forceps being, it was believed, more or less buried in the wall of the bronchus, granulations having probably formed around it. Attempts to grasp it at this stage failed. A gunshot probe was introduced, and a metallic sound became audible to the bystanders, the body being struck about four inches below the wound. A series of unsuccessful attempts to extract the forceps blade was

Digitized by Google

now made with every instrument available. It was seized by the forceps several times, but each time slipped out of their grasp, and this was evident both by sound and sight to those present. The blade could each time be reached at the same place; it did not change its position. Its proximal extremity was, so far as one could judge, an inch and a half below the bifurcation, in the right bronchus or one of its primary subdivisions, and, as previously mentioned, quite four inches below the lower extremity of the tracheal opening. (See Fig. 2.) There could be no doubt whatever as to the exact position of the body, for it was felt again and again, and the forceps introduced to extract it slipped again and again from its smooth surface. A piece of fine drainage-tube was slipped over one blade, in hopes that a better hold might be obtained on the piece of steel; but this failed. The patient had been placed in an almost inverted position, so that if loosened the piece of steel might fall towards the opening in the trachea. She was also well shaken, but without result. A wire loop was passed, in the hope of getting beyond and dislodging it, but this plan likewise failed, and the forceps were again resorted to. Urethral forceps and others were used, but with the same result as before, until the pair of polypus-forceps first selected were again introduced. This time they fortunately retained their hold, and the piece of steel was at length successfully withdrawn. The blades had grasped the narrow claw of the tooth-forceps; the larger end had probably lodged in the subdivision of the bronchus. The broken portion of forceps is shown in Fig. 1. It is about an inch long, with sharp margins and very irregular form. The weight is sixty-three grains. The position it was believed to occupy is indicated in Fig. 2.

Some trifling bleeding took place from the interior of the air-passage. It was decided, however, to close the wound. The loops of silk thread were withdrawn and the edges of the trachea brought accurately together by silk sutures; two drainage-tubes were put into the external wound, and the latter closed by four silk sutures and dressed with iodoform and iodoform gauze. All this time—about an hour and a half—the patient was kept partially under the influence of chloroform administered through the tracheal opening by a tube. She was conscious enough, however, to murmur thanks the moment the blade was extracted. When the patient was taken back to the ward a steam kettle containing water and some eucalyptus oil was placed at the head of the bed, which was screened off.

27th. — The patient had little sleep until early this morning, when a hypodermic injection of one-third of a grain of morphia was administered. When she coughs she complains of much pain and soreness in the right side of the chest, especially just above the level of the right nipple. She has coughed up a little blood and mucus. The wound was dressed, and presented a healthy appearance. At first air passed through it when the patient coughed; very little appears to pass now, and there is no emphysema of the neck. The tongue is clean; the pulse 112. Temperature at 8 A.M., 100·8°; respiration 20. She has a tranquil appearance: no anxiety or respiratory distress.

28th.—The patient slept well after two morphia injections, one at 4 P.M., the other at 10.30 P.M. She still complains of great soreness in the chest and right shoulder, especially on swallowing or coughing. There is no impairment of resonance over either lung; no difficult respiration, but scattered rhonchi are audible over both lungs, and moist sounds at the base of the right. There is but little cough; the expectoration is muco-purulent, and scarcely stained with blood. The temperature at 8 A.M. was 100·2°; pulse 112; respiration 21. The wound is looking healthy, but is gaping a little between the sutures below, and some air escapes through it. There is no emphysema.

Dec. 3rd.—The sutures were removed, and the upper part of the wound supported with strips of adhesive plaster.

5th.—Temperature, pulse, and respiration are reported normal. Expectoration very slight, with the merest trace of blood-staining. She feels well, and the wound is healing satisfactorily. Some air still escapes from its lower end, but there never has been any other trouble.

Very soon after the 11th, the wound was reported completely healed, save a very small opening below, through which a little air escaped. The patient seemed quite well.

The history of the case may be summed up very briefly. Except at the lower part the wound soon healed; here for a short time some air passed in and out, but by the middle of December the wound had all but closed, a slight amount of air gaining exit only on the patient coughing forcibly. The pain and other chest symptoms gradually and steadily abated, and had completely disappeared by December 10th.

Dec. 24th.—The patient may now be pronounced quite convalescent. The wound is perfectly closed, the cicatrix being linear. She has been up and about for the last week, and is enjoying her usual health. The chest sounds are normal. She says she feels perfectly well; her appetite is good; she sleeps soundly; and, in short, is in no respect different from what she was before the operation. Discharged.

Remarks.—This interesting case affords another example of the greater relative frequency with which foreign bodies in the air-passages find their way into the right bronchus. So far as I can learn, the accident here related is absolutely unique. Teeth have passed into the trachea, and tooth-forceps have broken many times before now, but the broken portion has fortunately not been inspired. The forceps in question has the imprint, at all events, of one of the very best makers. In this case the nature of the foreign body, its size, and pretty surely its exact position, were all known beforehand. This is very often otherwise in the case of foreign bodies supposed to be in the air-passages; the history is generally imperfect, the symptoms frequently obscure, or at times they may be altogether absent, so as to render the presence or absence of the foreign body doubtful. Yet, with all the knowledge we in this instance possessed, the extraction of the blade was only accomplished with the greatest difficulty. In an analysis of 1000 cases of foreign bodies in the air-passages, published in Vol. I. of the Transactions of the American Surgical Association, Dr. Weist states that "when the foreign body is impacted in one of the bronchi the chances of expulsion at the time of operation are small, and attempts at extraction by instruments generally end in failure." The measures at first employed in this case — inversion and emetics — cannot be regarded as free from the most serious risk of sudden death, unless the surgeon is prepared at once to perform tracheotomy; indeed, I consider tracheotomy should always be first performed before either is resorted to. Probably the body was in this case firmly impacted from the first, as it certainly was when attempted to extract it. The only means, I think, untried was a magnet, and that, although thought of, could not be obtained. I do not know of any other method more likely to succeed than by means of a forceps such as I first thought of, which ultimately proved successful. To this and the free opening of the trachea are due the credit of success. It is fortunate that so sharp and angular a body had not produced more serious ulceration. The air-passages bore the prolonged manipulation well, and the reaction afterwards was moderate, being limited to some localised broncho-pneumonia, that soon passed off. There was no hæmorrhage of any importance. The patient was kept under the influence of chloroform throughout, by a tube introduced from time to time through the opening in the trachea.

The drawing of the trachea and its relations is from the hand of my colleague, Mr. Anderson. It represents an average female trachea, half the natural size, and the position the body was believed to be in. The septum of bifurcation is from half an inch to three-quarters higher inside than it shows outside, so that the body is really much further from the bifurcation than the drawing apparently indicates. From the position it occupied between the blades of the forceps after extraction, it must, I think, have lain in the bronchus as it is represented in the figure, and its larger extremity had doubtless passed some distance into the principal subdivision of the bronchus, which is practically a continuation of the main tube.

Harley-street, W.

PATHOLOGICAL SOCIETY.—The following is the list of Officers and Council proposed for election for the year 1886:—President: Dr. Bristowe. Vice-Presidents: Dr. Charlton Bastian, Dr. Cayley, Dr. T. H. Green, Dr. George Johnson, Mr. Morrant Baker, Mr. Hulke, Mr. Sydney Jones, Mr. T. P. Pick. Treasurer: Mr. John Wood. Honorary Secretaries: Dr. Coupland, Mr. Butlin. Council: Dr. Carrington, Dr. Finlay, Dr. Goodhart, Dr. Hadden, Dr. Longhurst, Dr. Norman Moore, Dr. Semon, Dr. Seymour Sharkey, Dr. Charlewood Turner, Dr. Samuel West, Mr. Arthur E. J. Barker, Mr. Bowlby. Mr. Watson Cheyne, Mr. Henry Hugh Clutton, Mr. Frederic S. Eve, Mr. Golding-Bird, Mr. John Hammond Morgan, Mr. Henry Morris, Mr. Samuel G. Shattock, and Mr. Charters Symonds.

ON CHOREA, WITH REFERENCE TO ITS SUPPOSED ORIGIN IN EMBOLISM.

By W. HOWSHIP DICKINSON, M.D.CANTAB., F.R.C.P.,
PHYSICIAN AND LECTURER ON MEDICINE AT ST. GEORGE'S HOSPITAL, CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN.

DR. ANGEL MONEY, in a paper, published in the current volume of the Medical and Chirurgical Transactions, relates some experiments in embolism which have an important bearing upon the origin of chorea. Dr. Money introduced minute artificial emboli, starch-globules, and grains of carmine into the hearts and arteries of rabbits, guinea-pigs, cats, and dogs, with the production of embolism of the brain and cord, and the supervention, when the cord was affected, of choreic movements—"involuntary movements indistinguishable from those of chorea." The embolic theory of chorea, fathered by Kirkes and espoused by Dr. Hughlings Jackson, has thus received a sort of confirmation—a confirmation by synthesis, one to which it is impossible not to attach significance. This introduction of a new fact makes it necessary for those who, like myself, have been opposed to the embolic theory to reconsider their conclusions. Clinically, while the connexion of chorea with acute rheumatism is consistent with, and probably suggested, the embolic theory, the no less frequent origin of the nervous affection in mental emotion, particularly fright, is inconsistent with that hypothesis. It is a familiar observation that though the chorea of mental origin continually becomes associated with a cardiac murmur, yet that the chorea precedes any alteration in the rhythm or sounds of the heart, as if the cardiac were the result, not the cause, of the nervous disorder. Again, chorea displays a preference for families in which insanity, epilepsy, neuralgia, or other neuroses have declared themselves, as if nervous structure rather than vascular accident were in question.

I have a number of sections from the nervous centres in chorea which helped to form the basis of a paper in the fifty-ninth volume of the Medico-Chirurgical Transactions. I have reviewed these with the help of Dr. Money's observations and ten years' additional experience on my own part, and will proceed briefly to state the facts as they now present themselves, and collect the light which they throw upon the nature of the disease.

The facts of morbid anatomy may be thus summed up. There is in fatal cases of chorea a remarkable fulness of both arteries and veins in the upper part of the spinal cord and in the brain between the top of the cord and the lateral ventricles. The veins are more generally filled than the arteries, though the filling of the arteries, being more exceptional, is the more significant. Usually the vessels, whether arterial or venous, contain blood in a recent or unaltered state; but notably in one instance an artery under the corpus striatum, apparently a branch of the middle cerebral, contained decolourised clot, whether an embolus or a thrombus. This did not necessarily indicate more than past stasis, whatever its cause. The arterial fulness in this position so closely resembles what I have figured as occurring with diabetes mellitus,[1] that it is to be inferred that what is the nature of the one is the nature of the other. Whatever difference of opinion there may be as to the origin of the diabetic congestion, I presume there is none as to its existence, nor can there be any suggestion that it is embolic. In many parts, both in the brain and cord, but most numerously in the cord, are seen the results of erosion, exudation, and hæmorrhage. I say nothing about the so-called miliary sclerosis, or punctiform degeneration of the nervous tissue, which was found in some cases in close relation to the bloodvessels, because it is doubtful how far this is post-mortem leakage—post-mortem leakage from the distended vessel possibly favouring a peculiar kind of cadaveric change in the adjacent substance. Speaking, therefore, only of the unequivocal consequences of vital action, distension, erosion, exudation, and hæmorrhage, these are distributed with some approach to regularity in the affected regions, with greater frequency in some parts than others, more in the grey matter of the cord than in the white, more in the lateral portions of the grey horns than elsewhere, and more in the lower parts of the brain than the upper. The changes frequently approach, and sometimes present with completeness, a condition of bilateral symmetry; they are often further advanced on one side than the other, but it is the rule rather than the exception to find that if there be a marked hæmorrhage on one side, as in one horn of the cord, a lesser degree of hæmorrhage, or possibly only vascular fulness, will show that the corresponding part on the other side is in a similar or allied condition.

I will dwell in a little further detail on this tendency to bilateral symmetry, because, though it is not unknown for embolic accidents to occur with some approach to similarity on the two sides of the body, yet, if this symmetry can be shown to present itself with anything like constancy, a cause which acts with more regularity than embolism must be suspected. First as to hæmorrhage. In one case a great hæmorrhagic extravasation was found occupying a large portion of the grey matter on one side of the cord, while on the other side, in the corresponding position, were remarkably distended vessels. At the same level blood was extravasated into the anterior fissure, close to the commissure. In another case were considerable extravasations in the grey matter of the cord, in both dorsal and lumbar regions, similarly placed at the same level on both sides, at what may be considered the junction of the anterior and posterior horns. Blood was also found in the anterior fissure. Thus the extravasation especially affects the grey matter—I have never seen it in the white,—and is apt to concern both sides symmetrically. This points to selection rather according to function than by chance.

In other cases were symmetrical changes of other kinds, which were even more conclusive against embolism. In that of a boy who died with heart symptoms while convalescing from a severe attack of chorea, which had set in nine weeks previously, were found remarkable tracts of translucent degeneration in almost exactly the same regions on both sides of the grey matter of the cord, accurately bounded so as to exclude the white. The grey matter, which was changed chiefly by a destruction and removal of the nervous elements, the fibroid remaining unaffected—the degeneration would probably be called sclerosis, but I avoid the use of the word, as it has been applied to changes of a different and somewhat equivocal nature,—was affected with certain differences at different levels, but at each level in such a way that one side of the cord was almost exactly the counterpart of the other. In the paper referred to I have given a drawing of one half of the cord in this case, which drawing would serve, *mutatis mutandis*, to represent with almost equal accuracy the other half of the section. The parts chiefly affected were the lateral regions of the grey matter, together with the outer portions of the posterior horns. It is to be observed that the parts thus affected were nearly those which in earlier cases were the seats of hæmorrhage.

To conclude the evidence of bilateral symmetry in the lesions of chorea, and of their incompatibility with an embolic origin, I will briefly advert to a case related and figured in the Medico-Chirurgical Transactions—that of an old woman who died of chorea, which had lasted for four years. In the cervical and upper dorsal regions of the cord were *masses* or *pools* of nearly structureless exudation, which formed striking objects under the microscope. I say "masses" or "pools" because, though the exudations presented themselves as solid after the action of chromic acid, it is possible that they might not have been so during life, but have consisted of serum, which the hardening agent coagulated. Solid or liquid, they were there, were symmetrical, and occupied much the places which were chosen by other choreic lesions. The intruded material was similarly disposed in each half of the grey matter, chiefly at its outer or lateral parts and at the beginning of each posterior horn; it was also found in the anterior fissure. The post-mortems upon which I have drawn were seven in number, of which, it will be observed, I have been able to appeal to four in evidence of a systematic placing of the lesions, which must be regarded as purposive rather than accidental.

In further regard to the pathology of chorea and of embolism, it is to be noted that, while the lesions of chorea are mainly in the cord, though not confined to it, this part of the nervous system rarely presents the known and admitted signs of embolism. We easily recognise the appearances which this accident gives rise to in the brain; they are often visible, even conspicuous, upon the pia mater; but we do not see them in the cord, excepting as pyæmia,

[1] Renal and Urinary Affections, part i., pp. 36 and 37.

Digitized by Google

and then infrequently. It is true that the cord is less often exposed to view than the brain, but often enough to enable us to say at least that spinal embolism is rare, while chorea is common.

Again, if embolism of the cord ever occur, and no doubt it may without being found, it would probably be in those cases in which, together perhaps with evidences of embolism in many parts of the body, there is general and minute embolism of the brain. I have seen such cases, but never found chorea among their symptoms. Further, it may be stated as a general truth that where embolism is certified to after death by blocks, impactions, or other indubitable results of the process in one organ or many, there is no history of chorea. This statement will find confirmation in the experience of every physician who frequents the dead-house as well as the wards. But not to trust to impression or recollection, I will appeal to facts in detail as presented by the very complete post-mortem and case books of St. George's Hospital, together with those belonging to the Hospital for Sick Children, which are kept on the same plan.

I have examined the St. George's records from the time when I became curator in June, 1861, by which time embolism had become well understood, until October, 1885, comprising twenty-four years and 6787 examinations. One hundred and forty-seven of these gave evidences of embolism in the well-known shapes of blocks in the kidney, spleen, and liver, and plugging of arteries chiefly in the brain. From this enumeration I have excluded embolism confined to the right side of the heart and the pulmonary vessels, as the left side of the heart, and the systemic circulation only, can be supposed to be in relation to the nervous system. Among the 147 cases were but two in which there was any record of chorea. The subject of one of these was a girl of seventeen, whose chorea began with and was apparently due to illegitimate pregnancy. There was no history of rheumatism. The endocarditis and embolism succeeded upon the chorea and were apparently consequent upon it. There were blocks in the kidney and liver; there was no sign of embolism in the brain. The other case was that of a young woman who died at the age of nineteen, with heart disease and embolism, not cerebral. At the age of twelve she had had an attack of chorea, which, as far as was known, did not recur. These were the only instances of chorea among the 147 cases of embolism. The series included, generally many times over, every recognised result of embolism. There were thirty-four examples of cerebral embolism, together mostly with embolism elsewhere, and of these thirty-four were several in which the brain was permeated with "embolic dust"—emboli so finely divided and widely distributed as to promise any result which minute embolism general to the nervous centres could produce. To add to this the experience of the Hospital for Sick Children, I find that from January, 1860, to June, 1885, there were 1867 post-mortem examinations and eleven of embolism. Embolism, by this showing, is less frequent in children than adults. Chorea, as is well known, is far more frequent in children. In the eleven cases of embolism were two in which chorea was simultaneously present; one in which it had occurred, along with acute rheumatism, three years previously. Thus, of 158 cases of embolism from both sources, there were three in which chorea coexisted, two in which there was a history of it; at most, then, 5 cases of chorea in 158 of embolism. Thus, if chorea is a result of embolism, it must be a very infrequent one.

Let us take now another aspect of the question, and look at the co-evidence of embolism and chorea from the standpoint of chorea, these three cases in which embolism and chorea co-existed—the chorea displayed in the last illness and the embolism found afterwards—were the outcome of 27 cases of chorea, of which the post-mortems were recorded in the same books at the same time, 14 from St. George's, and 13 from the Hospital for Sick Children. Thus, in 27 cases of death with chorea, embolism was recognised but in 3. Considering the frequency of heart disease in chorea, whatever may be the nature of the association, embolism strikes one as occurring less often than might have been expected. Among these 27 cases of chorea, endocarditis was present in a recent state in 22 cases, with which in 5 pericarditis was combined. I have elsewhere discussed the nature of the connexion between heart disease and chorea. That embolism does not form the link is shown by its infrequency when endocarditis is present, and further by the exceeding infrequency of embolism when endocarditis is present. It is clear from the [illegible] that the endocarditis of chorea is often rheumatic; we do not as yet know how chorea is connected with rheumatism, though it is sufficiently obvious that it is so. In many cases where heart disease and chorea have concurred it has been manifest to clinical observation that the chorea has come first, the cardiac disturbance afterwards.

Table presenting concurrence of Chorea and Embolism in 8654 cases, with post-mortem examination: 6787 from St. George's, 1867 from the Hospital for Sick Children.

	St. George's.		Hosp. for Sick Children.		Total.		
	Male.	Fem.	Male.	Fem.	Male.	Fem.	Both sexes.
Embolism	83	64	8	3	91	67	158
Chorea	2	12	3	10	5	22	27
Embolism with chorea	—	1*	1	1†	1	2	3

* Besides this, there was one case in which a girl who died at nineteen with heart disease and embolism had had chorea at twelve.

† Besides this, there was a case of a girl in whom chorea and acute rheumatism had occurred three years before death, with embolism.

Human pathology, from whatever point of view we have as yet regarded it, gives no encouragement to the embolic origin of chorea; while it is almost conclusive against what is the same thing in a different light—chorea as a result of embolism. The clinical consequences of embolism are well known as gathered from cases in which the characteristic lesions have been found after death. Chorea has no place among them. Cerebral embolism often presents itself with sudden hemiplegia, which may be, but more often is not, briefly preceded by convulsive movements in the affected limbs, in no respect resembling the movements of chorea. The paralytic attack is usually without loss of consciousness; it is often on the right side, and with aphasia. Shivering, vomiting, pain in the head, sudden blindness, epileptiform convulsion,[2] drowsiness, delirium, and finally coma, are each occasionally present. Besides these, as the symptoms of the more chronic and localised shape in which the accident happens, there is an acute form in which "embolic dust" is widely distributed, which is characterised by symptoms which resemble those of meningitis or of one of the specific fevers—headache, vomiting, repeated rigors, high fever, and active delirium, but no localised paralysis. In this form the wide and probably general scattering would lead us to expect chorea, could this symptom result in the human subject from such a cause; but neither in the limited nor in the general form of the disorder is any such consequence to be recognised.

I will now apply another test to the supposed association of embolism and chorea as cause and consequence. It has been shown that chorea and the recognised manifestations of embolism have little tendency to present themselves together in the same individuals; do they concur in the same classes of persons as to age and sex? If the disease is a result of embolism, it is but likely that there will be some correspondence in the incidence of the two conditions—that where one is abundant there will the other occur with some frequency. Whether this is so, the following facts will show. Of the 147 cases of embolism from the post-mortem books of St. George's Hospital, 83 were in male and 64 in female subjects. This is of value as the experience of a large general hospital. Male admissions at St. George's Hospital are more numerous than female in the proportion of three to two. This does not rest on any inflexible hospital arrangement, but on the greater frequency with which men apply, owing, no doubt, to their greater share of accidents and exposure. The post-mortem books at the Hospital for Sick Children give 8 cases of embolism in the male and 3 in the female. Thus it appears that at every time of life embolism is the more frequent in the male. It must at least be allowed that this disorder does not fall upon the female with any preponderance. Now as to chorea, the proclivity of which for the female sex is almost too familiar to need illustration. A glance at the annexed summary of post-mortem results shows 22 deaths of females to 5 deaths of males from this cause; and clinical evidence tells in the same direction. At the Hospital for Sick Children I had charge for a time of both boys and girls—for a time of boys only, for a time of girls only. Putting

[2] See report of two cases of Cerebral Embolism by W. H. Dickinson, British Medical Journal, May 21st, 1881.

Digitized by Google

aside the fatal cases which I have already spoken of, I was enabled to tabulate in the paper already referred to the particulars of attacks of chorea affecting 69 children. Of these, 50 were girls, 19 boys. To take the more recent experience of the same hospital, and as a whole, without distinction of physician, I have learned from Dr. Chaffey, the present registrar, that in the last seven years 472 patients were admitted with chorea—336 girls, 136 boys. Thus embolism and chorea differ in their incidence. One has little sexual preference. Of the other the sexual preference is strongly marked.

Next as to age. Embolism is connected with antecedent disease—rheumatism or other. Acute rheumatism is less frequent in childhood than in early adult life, and the other changes to which embolism is due are mostly more chronic and of still later occurrence. Thus embolism belongs rather to adult life than to childhood, while chorea belongs rather to childhood than adult life. At St. George's Hospital, where patients of all ages are admitted, the results of embolism were found on an average once in 46 post-mortems. At the Hospital for Sick Children, where the patients range from two to twelve, these results were found once in 169 post-mortems. Thus embolism is nearly four times more frequent in a mixed community than in a community of children. At St. George's the patients admitted with embolism varied in age, the males from 15 years to 74 years, the females from 3 years to 66 years. The average age of the males was 38, of the females 29, of both together 34. As to chorea, the ages of the two male subjects was in each case 11 years. That of the females varied from 7 years to 54 years, giving an average of 17, raised thus high by what may be termed the accidental or at least the exceptional inclusion of the case fatal at the unusual age of 54. The average of the male and female cases together was 16. Thus from the experience of a general hospital, where there is no exclusion on the ground of age, persons die with embolism at a mean age of 34, with chorea at a mean age of 16, the last figure being no doubt higher than it would commonly be owing to the exceptional case to which reference has been made. Chorea thus belongs to an earlier period of life than embolism.

To recapitulate the evidence which has been adduced for and against the embolic origin of chorea.—When chorea is associated with acute rheumatism, endocarditis often precedes the nervous affection. When chorea arises otherwise, as in fright, the nervous affection may precede any cardiac disturbance, the valvular lesion in such cases being, so far as clinical observation can show, not the first departure of the disease, but acquired in its course. Chorea is apt to occur in neurotic families. Pathologically, though the lesions of chorea are mainly vascular and perivascular, as are those of embolism, yet the parallelism does not extend into particulars. The distended vessels of chorea almost invariably contain blood-corpuscles, not fibrine; and the lesions have a bilateral symmetry, and proneness to repeat themselves in certain places functionally chosen—habits consistent with an origin in nervous disturbance, not with one in embolism and accident. After death with chorea the embolic process was found to have occurred in some part of the body in a tangible proportion of cases—3 in 27. But taking the frequent concurrence of valvular disease and chorea, however accounted for, the proportion of embolism is probably no more than would be reckoned on as due to the heart disease, even though it were presumed that the accident had no connexion with the nervous disorder. That there is no necessary connexion between embolism and chorea appears by the absence of the disease among the recognisable consequences of embolism. One hundred and forty-seven cases in which this lesion was found at St. George's gave but one of chorea; among children chorea presents itself with more frequency, but, nevertheless, 3 in 158 represents the total concurrence. Next, embolism is distributed between the sexes not very unequally, the male taking the larger share. Chorea is about three times more frequent in the female than in the male.

Finally, it has been shown that embolism selects a later time of life than chorea, the average difference being probably under-stated by that between thirty-four years and sixteen. This selection by chorea of females and the young, while embolism displays no such partiality, is not conclusive against their relation as effect and cause, though it tells in that direction. It is conceivable that female children may have a special susceptibility, in virtue of which they develop chorea from a cause which is insufficient to produce it in the male. Alcohol causes paraplegia in the female, seldom in the male; delirium tremens in the male, seldom in the female. It is not improbable that some of the causes of chorea may be presented equally to both sexes, but affect them unequally; and so it may be with embolism. But embolism is a coarse, mechanical accident, the consequences of which are not likely to be dependent on special susceptibilities. A storm of emotion may shake or shatter the more tender structure and leave the tougher unhurt; but we have no reason to attribute any such partiality of effect to the impaction of clots. The probability is that if chorea is a result of embolism, where embolism is there will be chorea. Putting all the evidence together, it appears to me to be conclusive against the embolic origin of chorea. Dr. Money's artificial embolism caused many varieties of abnormal or forced movement, of which chorea was one. If the right place be irritated, we have no reason to suppose that the irritant must always be the same. The irritation, for aught we know, may begin in one case in the vessel and affect the nerve, and in the other begin in the nerve and affect the vessel. The artificial process may be somewhat similar in its results to the natural one, and yet the *modus operandi* of nature and art be essentially different. In both we can recognise plugged or distended vessels, and must infer the irritation of certain motor centres, but we need not assume a resemblance in all particulars or identity of origin. It by no means follows that because choreic movements are among the results of artificial embolism in animals, chorea as a disease is the result of embolism in man. Dr. Money, in his valuable and judicious paper, carefully abstains from drawing this conclusion, and I venture to think that the facts I have adduced justify his caution in this respect.

Chesterfield-street, Mayfair, W.

NOTE ON

ANKLE-CLONUS AS A SYMPTOM IN CERTAIN FORMS OF NERVOUS DISEASE.

BY W. S. PLAYFAIR, M.D., LL.D., F.R.C.P.

I HAD not the advantage of being present at the discussion at the Medical Society at which Dr. Gowers read his very interesting paper on the "Diagnostic Value of the so-called Tendon Reflexes." In this Dr. Gowers maintains, but with more reservation than in his book on "Diseases of the Spinal Cord," that the occurrence of distinct ankle-clonus may generally be taken as a proof that a given case of hysterical paraplegia, as well as other cases of supposed functional nervous disease, is really of structural origin. If this fact could be relied on as a certain sign of such structural changes in the spinal cord as preclude the hope of permanent cure, or of such amelioration in the walking powers as is tantamount to it, it would be an immense help to those who have to face the almost insuperable difficulties of diagnosis which sometimes present themselves; for the symptom is one easily tested. The fact that I have chanced to direct attention in THE LANCET to the so-called "Weir Mitchell Method" of treating certain forms of functional nervous disease in women has given me the opportunity of seeing many obscure cases of this kind, and I have naturally had my attention directed very closely to this point in the hope of avoiding an error of diagnosis. In many doubtful cases I have had the advantage of consultation with Dr. Buzzard, as well as with other neurologists equally distinguished, and to some of these Dr. Buzzard referred in the discussion which followed the reading of Dr. Gowers' paper, when he said he had seen with me "ankle-clonus, quite indistinguishable from that which was characteristic of lateral sclerosis, occur in many cases of hysterical paraplegia, in which, on recovery, it ceased to be elicited." I am perfectly satisfied that if the presence of true clonus should always be taken as a contra-indication to a well-directed and systematic effort to cure certain cases of functional or "nutritional" nervous disease, as Dr. Gowers so wisely suggests they should preferably be called, then the serious error would be fallen into of leaving untouched cases quite within the possibility of cure. Dr. Gowers says: "I have never seen an unquestionable instance of it"; I can positively state, on the other hand, that I have

Digitized by Google

seen not one but many cases in which, at first, a perfectly characteristic clonus was obtainable, and in which, under the improved nutrition and increased strength following systematic treatment, this symptom steadily and progressively diminished, being constantly tested from time to time, until at last it could not be elicited at all. In these I commenced treatment with doubt and anxiety on account of the presence of the clonus; and, had it not been for Dr. Buzzard's encouragement, some of them would have remained uncured to this day, so far as I am concerned. As was only natural, therefore, I paid very particular attention to this point, and I cannot be mistaken as to the issue.

It is needless to burden this note with cases, but I may refer, in illustration, to two marked examples which I well remember.

Mrs. D——, aged fifty-two, completely paralysed in her lower extremities for twenty-five years. Has never moved off her couch all this time except occasionally across the room on crutches. Exaggerated knee-jerk and distinct clonus. A year has elapsed since I last saw this patient, and then it was impossible to elicit any clonus at all. She has since remained perfectly well, is able to take long walks, to visit amongst her friends, &c.

Miss I——, aged thirty-five. Seventeen years practically bedridden. Here, again, clonus was quite distinct. Two years have elapsed since this patient was under my care.

I select these cases because Dr. Buzzard saw them with me, so that there can be no doubt that the clonus noted was not the "spurious foot-clonus" Dr. Gowers refers to.

Dr. Gowers says very pertinently: "Cases of hysterical paraplegia with excess of myostatic contraction get better, but do they get well? The patients regain the power of walking, but not of walking well; they remain what is popularly called bad walkers, soon tired, even with standing." This seems to me exceedingly probable, but it is obvious that if such patients can be made so far better that they discard their crutches, give up their beds, and cease to be the miserable invalids so many of them are, then they get, at any rate, well enough to justify any efforts at cure, in spite of the pre-existence of an excess of myostatic irritability. I by no means intend to under-estimate the grave import of this symptom; all I contend for is that it must not be too exclusively relied upon in settling the diagnosis of a doubtful case. I heartily wish, for the comfort of those who are responsible for the diagnosis, that it could. The solution of the riddle will probably be found in the direction of Dr. Gowers' suggestive remark: "That in many of these cases there must be a change, and a considerable change, in the nutrition of the nerve elements—sometimes, it may be, springing out of a mere functional derangement, but always maintaining and increasing that derangement." It is because of this, I believe, that the systematic treatment of these cases often has such surprising results. Beyond and above the moral effects of removal from unwholesome domestic surroundings, and the personal influence of the medical attendant, the improved nutrition of her whole body is such as no one can believe who has not seen the results, and with this increased nutrition comes the disappearance of the symptoms. But that there is always a considerable risk that in old-standing cases of this special form of neurosis the impaired nutrition of the central nervous system may have led to the establishment of progressively increasing structural disease is a fact which, I believe, increased experience in this very obscure class of disease will prove to be the case. This, I cannot doubt, is the true explanation of the occasional want of success in the treatment of cases in which the diagnosis of so-called "functional" disease was beyond question. This everyone who has tried to cure many of these cases must have met with; nor is it any reason why the attempt should not be made. Hitherto, when we have had to deal with a case of "hysterical" or "functional" disease, we have all been too much in the habit of simply establishing the fact, forgetting that patients come to us, not to be diagnosed, but to be cured. If the patient have the good fortune to come under a "faith cure," or to go to Lourdes, or to fall into the hands of anyone, whether a regular or irregular practitioner, who has sufficient moral influence over her, now and again a cure of this lamentable illness may occur in a hap-hazard sort of a way; otherwise she may linger on for half a lifetime, a burden to herself and all who come in contact with her, but no medicine will touch her case. Whereas, as a matter of fact, she is suffering from a class of disease which, rationally and scientifically treated, is more completely within the resources of our art than almost any of the diseases which "flesh is heir to," although doubtless the cure requires an enormous amount of patient work.

ON THE

IMMEDIATE OCCLUSION OF THE CORNEAL WOUND AFTER EXTRACTION OF CATARACT.[1]

BY DR. GALEZOWSKI.

THE operation of extraction of cataract has made of late very rapid progress, and the results obtained now are most satisfactory, failures being only seen in cases altogether exceptional, such as traumatisms, or when the general condition of the patient is extremely weak and broken down. The success of the operation depends, without doubt, on the manner of operating, as well as on the subsequent care and post-operative dressings. After the labours of Jacobsen, Mooren, and De Graefe, ophthalmologists throughout the world adopted the principle advocated by these eminent German authors—that, in the extraction of cataract, it was necessary to excise the iris, as by so doing the suppuration of the corneal flap was prevented; and they used to practise it either on the peripheral border (sclero-corneal) or on the sclerotic proper, thus enabling the wound to take almost linear form and become easy of coaptation. This was the opinion that prevailed among ophthalmologists, and which has been accepted until now by the majority of surgeons.

I was the first who, in 1882, had the idea of returning to the extraction of cataract without incision and avoiding the incision of the sclerotic and placing it altogether on the cornea, seeing that suppuration supervened after extraction in spite of previous excision of the iris, as recommended by Mooren, or the extraction proper. The results of this operation have been more favourable than those of De Graefe, as it has been demonstrated by my memoir to the Société de Chirurgie in 1882, and also by my report to the Société Française d'Ophthalmologie and to the Congress of French Surgeons. In all these reports I have tried to demonstrate three important points, and upon which I insist to-day more than ever. 1. That if I abandon the German method and incline myself to the French method, it is because there are in my incision and *modus operandi* other conditions of execution altogether peculiar, that allow me to consider it as my own special procedure. 2. That the excision of the iris cannot and must not be abandoned entirely, but must be reserved for cases altogether exceptional, such as when the iris is adherent, posterior synechiæ, when the lens is dislocated or the nucleus floating, when the capsule is opaque, and when it is to be extracted at the same time as the lens. 3. That the results of the operation depend as much on the manner in which it is practised as on the post-operative dressings. In a work I am now preparing, and which follows my studies on cataract in general, I intend to develop successively all the questions that relate to my first two points. My third proposition, which relates to the post-operative dressing plays a very important *rôle*, as I have already stated, and has engaged my attention for a long time. I was constantly endeavouring to ascertain the cause that brought on suppuration of the wounds in certain individuals without any plausible reason. The general hygienic conditions, atmospheric influences, and morbid constitutions have been analysed and computed successively, but nothing could explain these accidents, which arose sometimes where one least expected them. Returning to the principles of Pasteur, that suppuration could not be produced except by the poisoning of the wound by microbes, I thought that the tears might, even in normal conditions of life, contain microbes, and that in certain pathological conditions they could multiply and be brought into contact with the corneal wound, infect it, and bring on suppuration in it. This question could only be elucidated by delicate microscopical observation of the tears. I entrusted one of my pupils, Dr. Salterain, of Monte Video,

[1] Memoir read at the Academy of Medicine, Oct. 6th, 1885.

Digitized by Google

to make a complete study of the microscopical composition of the tears. He has made it, with the kind help of Dr. Poey, of Monte Video, and here follows the result of their first research:—

"*Microscopical researches on the microbes of the tears.*—The result of the first experiments, which require to be repeated and controlled, were made at the Clinique d'Accouchements, and is described in the following manner. The direct examination of the tears by the microscope not having given any positive results, we took a drop and deposited it in one of the globes of culture used for these experiments. Three days afterwards the broth became turbid, and on examining the liquid we found in almost every instance (three were doubtful) monococcus, diplococcus, and masses of zooglœa. In one of the globes we also discovered some long chainettes well developed. The number of experiments has been fourteen, and, with the exception of three cases, we found the same elements in all."

What conclusions can we draw from these researches? Is it not that the same element that has been observed in purulent ophthalmia and in the pus of the lacrymal sac of dacryo-cystitis exists, though in smaller quantity, in the normal tears? The recent labours of Schmitt-Rimpler and of Satler have demonstrated that the pus of the lacrymal sac contains varied forms of micro-organisms. The existence, then, of microbes in healthy tears, mixed with the pus of the lacrymal sac, is no longer doubtful. It is easily understood that if the microbes multiply while the lids are closed, and the secretion of the ocular mucous membrane and of the sac increases and is retained, the corneal wound, remaining open and lubricated by the tears, more or less altered, suffers an imbibition and impregnation of the latter, the microbes penetrate the wound and develop an irritation, an infection of its borders, and a suppuration, with all its consequences. To remedy this danger I have sprayed the eye during and after the operation with phenicated vapours, that could not diminish the predisposition to the multiplication of germs. I employed, following the example of other authors, the antiseptic treatment of boric acid, of phenic acid, and sublimate; but all these means can only be of use when brought in contact with the wound, as they lose their action the moment the eye is closed and the lids are compressed by the bandages. The suppurative accidents took place, however, though less often than with the old dressing.

After all these unsuccessful experiments, directed especially against the microbes that I wanted to destroy, I thought that there would be more advantage in trying to protect the wound against the penetration of microbes, and to favour cicatrisation by first intention. My object was to apply a glutinous substance directly over the corneal wound. The problem was difficult to solve, as it was necessary to find an adherent substance which would not by its contact irritate the cornea or the conjunctiva. After numerous experiments I was able to compose a species of gelatinous plaster that can be easily borne by the eye, becomes adherent to the wound, melts gradually in the tears, and disappears at the end of ten or twelve hours. This preparation is no other than very thin sheets of gelatine, very flexible, and prepared for me by Mr. Wusk, the pharmacist. To employ with advantage these sheets of gelatine, and to keep them in position a sufficient length of time, they must have a certain thickness; those I use ordinarily are half a millimetre thick, but I think they can be made thicker. To enable the eye to resist better the gelatine, I have both surfaces of the sheet covered with a concentrated substance of cocaine, and I add also a weak solution of sublimate in the proportion of 25 centigrammes per 1000. One face of the sheet is also covered with a layer of special glue, that fixes it lightly on the cornea, and prevents its displacement by the friction of the lids. By calculating the amount of sublimate and cocaine employed in the preparation of the gelatine sheets, I may say that a square centimetre contains on either side, more or less, 0·01 of chlorhydrate of cocaine and 0·0005 of sublimate. I use habitually small squares of one centimetre and a half, with rounded angles, and in which I make small cuts on one of the sides. The pieces of gelatine, thus prepared, I take with a pair of thin and flat forceps, and after dipping them in warm water I insert the non-cut border under the upper lid; I place then the cut border under the lower palpebral border, and close the eye by applying a compressive bandage. The results of this dressing have been until now extremely satisfactory. I have applied it in many of my cataract patients, and the closing of the wound by first intention with complete coaptation of the borders of the wound have been most rapid. I usually open the eye from forty-eight to seventy hours after the operation, and I have always found the wound united and the eye almost completely cured; in this way I have been able to remove the bandage on the fourth or fifth day. I have never found in the eye the smallest trace of the gelatine sheet, which proves that it dissolves completely in the tears. Some of my patients have complained of some heat and prickings for half an hour to an hour after the operation; others have complained of grittiness the first night, but never so strong as to require interference. I have already used this gelatinous dressing in nineteen cases of extraction of cataract, in one case of conic pellucid staphyloma, and in one iridectomy made in a case of perforating ulcer of the cornea, and in all these cases I have obtained union by first intention, without the slightest trace of irritation. One of my cataract patients had an old suppurative dacryo-cystitis with double cataract. Living in the country, he could not wait to have his lacrymal complaint cured, so I was forced to operate on him in spite of the suppuration of the lacrymal sac, and the gelatine dressing gave in this case as satisfactory results as in the others. The wound was united by first intention after the fourth day, and I then removed the bandage and was able to resume catheterism of the nasal duct on the following day. The following is the clinical history of this case by my *sous-chef de clinique*, M. Desjagnets:—

"*Right cataract; operation; suppurative lacrymal tumour of the same eye; cure, with complete re-establishment of sight.*—Mr. T——, seventy-two years old, farmer at Gouvieux (Oise), had a left double complete cataract. This eye was operated on at the Clinique on Sept. 28th, 1875. The operation was performed by the method adopted by M. Galezowski for the last three years—upper corneal flap without iridectomy. The dressing was made with a sheet of antiseptic gelatine placed on the wound. The patient previously had lacrymation of the same eye, for which the inferior lacrymal point was incised and catheterism practised for eight days. The lacrymation and subsequent conjunctivitis had been sufficiently alternated to enable the operation of extraction to be performed. The day after the operation the bandage was not removed, as the patient complained of no pain whatever. On the second day the eye was examined and found in excellent condition. Good coaptation of the wound resulted, the anterior chamber was re-established, the pupil being very free, but the whole anterior region of the sac was red, swollen, and inflamed. By pressing lightly on this region pus exuded from the lower incised point. A lacrymal tumour had formed in the sac, which had been sounded eight or ten times previously. In spite of the recent extraction, a sound was again passed, and a compressive dressing applied. After that date the dressing was every day saturated with pus. When removed, the eye was found bathed in the same pus; nevertheless, the eye remained without inflammatory reaction and in a perfect state. Every day the sounding was made, and after emptying the sac twice a day the eye was washed with a carbolic solution of 1 per cent. After eight days the suppuration disappeared almost completely, and the cicatrisation of the corneal wound was almost complete. On Oct. 9th the patient was discharged with a splendid eye, the normal acuity being V=1."

It would be superfluous for me to insist further on the advantages of the gelatinous antiseptic dressing; these have been daily evidenced. The satisfactory results obtained until now make me think that it will soon become generally adopted, not only in the treatment of corneal wounds after the extraction of cataract, but also in the dressing of ulcers of the cornea, and wounds and burns of the cornea and conjunctiva; and also that different remedies can be incorporated with the sheet and brought into contact with the cornea, and act successfully in cases of perforating ulcers and other forms of keratitis.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The following officers have been elected for the Session of 1885-86:—President: Dr. Robert E. Carrington. Vice-Presidents: Messrs. C. H. Hartt and F. B. Jessett. Council: Mr. Brindley James, Mr. W. C. S. Burney, Mr. Hughes G. Cable, Dr. W. Collingridge, Dr. A. Forsyth, Mr. J. Marshall, and Mr. F. Moon, M.B. Treasurer: Dr. Prior Purvis. Secretary: Mr. H. W. Roberts. Librarian: Dr. J. B. Saundry.

THE ETIOLOGY OF FOOT-AND-MOUTH DISEASE.

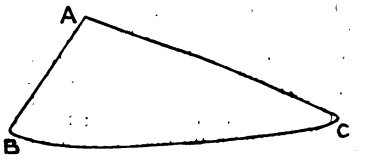
BY E. KLEIN, M.D., F.R.S.,
LECTURER ON GENERAL ANATOMY AND PHYSIOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, LONDON.

FOR some time past I have been engaged in an inquiry into the etiology of foot-and-mouth disease carried out for the Medical Department of the Local Government Board, and I have ascertained that this disease is caused by a micrococcus, which I obtained by cultivating artificially the lymph taken from the vesicles of a sheep affected with this disease. This micrococcus is present in the lymph and in the tissue of the vesicles as dumb-bells and as chains. It grows well in alkaline peptone and broth, in solidified blood-serum, in solid agar-agar peptone broth mixture, in solid nutritive gelatine mixture (which is not liquefied by it), and in milk. Its mode of growth in solid media is so typical and characteristic that by the naked-eye inspection alone it can easily be detected. When any of the above solid media is inoculated with this micrococcus, after several days a thin limited film makes its appearance at and immediately around the point of inoculation; this film slowly spreads, but from the outset and afterwards presents a very characteristic appearance to the unaided eye, being in fact *a collection of closely-placed minute granules or droplets.* These gradually and slowly enlarge, and assume a whitish, translucent character. If the inoculation is made with the point of a needle or platinum wire, or of a capillary pipette, pushed into the solid medium, the channel of inoculation becomes, after several days to several weeks, marked as a linear aggregation of minute granules or droplets; in addition to this there is on the surface the above-mentioned film of granules starting from the point of inoculation. The growth of this micrococcus is extremely slow; in solid nutritive gelatine mixture, kept at temperatures from 18° to 22° C., the first traces of the growth in the shape of a small cluster of transparent granules visible under a lens are noticeable at the end of from five to eight days, or even later; in agar-agar mixture, kept at 35° to 38° C., it is of course sooner visible, but even after six or seven months, in all media and under all conditions, the growth remains of limited extent. Also in milk, kept at temperatures varying between 35° and 38° C., the progress of the growth is extremely slow; the milk retains perfectly its natural aspect and condition; no curdling occurs, although the reaction becomes distinctly acid.

In artificial media the micrococcus forms, besides dumb-bells (diplococcus), beautiful chains (streptococcus). These differ in length according to the number of micrococci composing them, the short chains being a linear series of four, six, or eight micrococci, the longer ones of more than eight up to thirty and more micrococci. The longer chains are always curved, and even convoluted. The above-mentioned characteristic granular appearance of the growth is owing to the presence of smaller or larger masses of chains matted together.

Subcutaneous inoculation with artificial cultivations produces no perceptible disorder, but by *feeding* sheep with [illegible] with a twentieth generation—*the typical disease has been reproduced*—viz., vesicles and ulcerations on the feet. From the vesicle of such an animal lymph was obtained which, on cultivation, yielded the same micrococci, characterised by the same slow growth and the same typical general appearance as those used for the experiment. There can, then, be no question about the identity of this peculiar micrococcus with the cause of the disease.

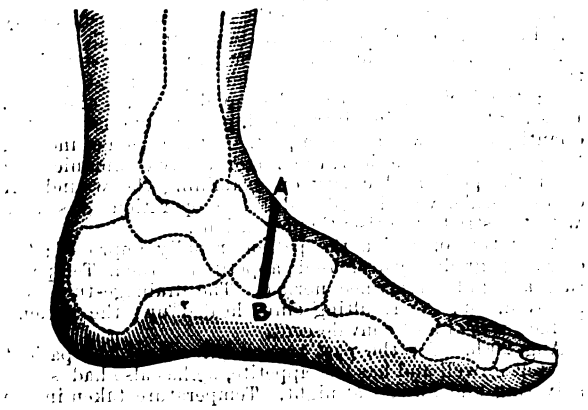
Five sheep have been subcutaneously inoculated with active cultivations of the micrococcus, but neither locally nor generally was there any definite perceptible change produced. Subsequent feeding of these same sheep with the active micrococcus had no result. I conclude from this that [illegible] subcutaneous inoculation with the micrococcus [illegible] animals with immunity against the disease. I hope [illegible] to be able to test this point on a larger series [illegible].



[illegible] inoculation of the same micrococcus into [illegible] produced no result; feeding was followed by [illegible] two to three weeks. Out of six animals [illegible] with their food a small quantity of milk containing the micrococci, three died—one from ulceration and perforation of the upper end of the duodenum, and two from ulceration and perforation of the large curvature of the stomach.

OSTEOTOMY WITH CHAIN-SAW FOR TALIPES EQUINO-VARUS OR VALGUS.

BY HORATIO P. SYMONDS,
SURGEON TO THE RADCLIFFE INFIRMARY, OXFORD.



FOR some time, having noticed how exceedingly prolonged was the treatment of even a simple case of talipes—and I may add how bad sometimes was the result,—it occurred to me that if we were to divide the bones in the same manner in which we divide the tendons a far better result might be obtained; better because quicker, since many cases fail on account of the patient's lack of confidence through seeing improvement taking place so slowly. I may state that I have performed the wedge-shaped removal and pegging, as advised by Dove and Ogston, but did not find the result sufficiently satisfactory. The operation I perform in all severe cases of talipes is to pass a chain saw round the tarsus, in front of the astragalus. Taking the tarsus as a triangle, pass a metal-handled tenotomy knife through the sole of the foot in front of the os calcis, B C, commencing from the inner side (see Fig. 1).

FIG. 1.

Then let the chain follow the knife through the sole, and repeat the proceeding from the outside to the dorsum of the foot (A). Complete the skin incision (A B), and then cross the chain so that it can gradually work its way outwards. The inner wound is sewn up, no drainage being necessary. The foot is then fixed on to a Volkmann's splint for a fortnight, at the end of which time, after manipulating it into a good position, it is fixed in plaster-of-Paris for three months (see Fig. 2). I recently saw a case in which I had

FIG. 2.

performed this operation eight months previously, and the patient was then walking without apparatus of any kind, and the foot, which before the operation had been very markedly deformed, was restored to its normal position. I need hardly say that the operation must be done with strict Listerian antiseptics, particular attention being paid to the condition of the saw.

SIR JAMES SAWYER, M.D., was entertained on the 22rd ult. at a banquet, at Birmingham, by a number of his professional brethren who were desirous of showing their appreciation of the honour—that of knighthood—recently conferred upon him by the Queen.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum propriis collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SEAMEN'S HOSPITAL, GREENWICH.

THREE HEPATIC ABSCESSES; OPERATIONS; RECOVERY.

(Under the care of Dr. CURNOW and Mr. JOHNSON SMITH.)

FOR the following notes we are indebted to Mr. E. H. Booth, M.B. Lond., house-physician to the hospital.

Frederick W——, aged seventeen, sailor, was admitted on July 14th, 1885. He came to the hospital complaining chiefly of pain over the lower part of the right side of his chest, and of cough. The following were the chief points in his history. He had been quite well up to fifteen months ago, when he had a severe attack of dysentery whilst in Java. He recovered at the end of three months. His present illness commenced nine months ago; he attributes it to his getting wet through and remaining for some time in his wet clothes. Soon after he suffered from pain of an aching character over the lower part of the right side of his chest, together with a dry cough, occasional shivering, and perspirations, the latter being worse at night. These symptoms had persisted, and, becoming more severe, he had come to the hospital for advice.

On admission, he appeared to be well nourished, though somewhat anæmic. He had pain and tenderness over the lower part of the right side of his chest, the pain extending from the back round the side; he also had a troublesome dry cough. Tongue dry; no appetite; bowels constipated. Tenderness on deep pressure over the hepatic region. Liver slightly enlarged, the edge just being perceptible to touch beneath the margin of the ribs. His chest was dull over the base of the right lung, and some dry crepitations and a few crackling friction-sounds were heard. There was a slight deficiency of vocal fremitus, breath- and voice-sounds over the same area. Temperature 103°; pulse 104.

July 27th.—Patient remained in much the same condition up to this date; his temperature rising at night to 101° or 102°, with slight shivering and sweats, falling in the morning to 98° or 99°. The chest mischief remained stationary. A puncture with the exploring needle was made in the eighth intercostal space; the needle was pushed fully two inches into the liver and a little pus drawn off.

29th.—An anæsthetic having been given, an incision about two inches long was made in the eighth space, parallel to the ribs; the incision was carried deep down into the liver. Dressing forceps being introduced, pus freely escaped; the quantity let out was almost a pint. At the region of incision there were no adhesions, the finger freely communicating with the peritoneal cavity on examining the wound. A drainage-tube was introduced. The operation was done with the strictest antiseptic precautions.

After this operation the patient rapidly improved; the discharge gradually decreased; appetite returned. Temperature and pulse remained normal. The drainage-tube was removed, and the resulting sinus healed up; the patient, in fact, was almost convalescent.

Aug. 20th.—For the past two or three days the patient has felt unwell and has lost appetite, he has also had slight shivering and sweats at night. Temperature taken in the evening was found to be 100°.

25th.—These symptoms continued; evening temperature rising to 102°, morning temperature 99°. It was suspected that pus had reaccumulated in the old abscess cavity. An anæsthetic was given and the old sinus laid open, the incision being carried deep down—i.e., into the site of the old abscess. Only a little blood-stained serum escaped. On introducing the finger, the old abscess cavity was found contracted to the size of a walnut. Pus being suspected in some other region of the liver, an exploratory puncture was made in the tenth space behind, about one inch external to the erector spinæ, and pus was drawn off. An incision about two inches long was made in this region. This incision had also to be carried deep down before reaching pus, when about half a pint was let out. One finger introduced into this abscess cavity, and another finger into the old abscess cavity, showed that the two abscesses were distinct, the two fingers not being able to get near one another. A drainage-tube was introduced. This operation was also performed antiseptically, and, as in the first, the finger in the wound was in free communication with the peritoneal cavity.

The patient again rapidly improved and was almost convalescent, when, on Sept. 10th, he began to feel ill, shivered, and had perspirations. The temperature, which had been normal morning and evening since the day of the last operation, again went up to 102° at night. Under an anæsthetic, the sinus leading into this last abscess was opened up, but only a small quantity of blood and pus escaped.

Sept. 19th.—The symptoms continued. Temperature in the evening 104°. Patient getting very thin and unable to retain food, and during the last three or four days has had severe diarrhœa. On careful examination a very slight bulge was detected high up in the axillary region—i.e., over the fourth and fifth intercostal spaces. Exploration was made and pus drawn off. An anæsthetic was given and a free incision was made into this third abscess; about one pint of pus escaped. On introducing the finger, the abscess was found to be situated in the upper region of the liver, the layer of liver substance between the abscess and the diaphragm feeling obviously thin and flaccid.

The after-treatment in this case did not differ in any way from that following the two previous operations. The drainage-tube was removed on Oct. 13th. The patient visibly improved from the day of the operation, recovering appetite, diarrhœa ceasing, and rapidly gaining flesh. He was discharged from the hospital on Nov. 20th, convalescent.

Notes by Dr. CURNOW.—This case well illustrates—(1) That in all cases of suspected abscess of the liver, explorations should be made in many directions; fluctuation, bulging of the ribs or local œdema should not be waited for, otherwise an abscess may exist and not be found. (2) The advantages of the treatment by free incision with the strictest antiseptic precautions, over aspiration or partial evacuation. 3. The non-necessity of waiting for adhesions before operating; in fact, the difficulty is rather to find the abscess, than to treat it under the Listerian method when its existence has been proved. The case is further remarkable for the successive formation of three distinct abscesses, and must suggest the possibility of their being due to absorption from the colon, for this patient had previously suffered from dysentery, and this has been our invariable experience at the Seamen's Hospital.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY.

CHOREA AND EPILEPSY.

(Under the care of Dr. FRANCIS HAWKINS.)

CASE 1. *Choreic movements in a boy five years old; recovery; purpura four months afterwards.*—Giles J——, aged five years, a schoolboy born in London, was admitted on Aug. 14th, 1885, complaining of having spots over his legs, and "pains" in both knees. His father, a tailor by trade, has very good health, the mother also is strong and well; there are four other children, two boys and two girls, older than the patient, all of whom are quite well. There is no history of any nervous disease or of rheumatism in the family, nor in any of the patient's ancestors. The house is comfortable, and much better than the majority of houses inhabited by the poor. The food has been fairly good, with the exception that no vegetables except potatoes have been eaten for some time. The patient has never had measles or scarlet fever, and was quite well until Dec. 24th, 1884, when the mother noticed that both arms "twitched" a good deal. The twitching continuing and increasing, the patient was taken to Middlesex Hospital on Jan. 13th, 1885, when the following note, taken from the out-patient card, was made:—"Slight choreic movements of both arms (more especially the left), which have existed for three weeks." The choreic movements gradually became less, and the patient ceased attending at the Middlesex Hospital on March 9th, 1885. The present illness began on July 22nd, when the mother noticed a number of small spots on both legs. The spots have continued to the present time (August 14th), but vary in brightness. The patient is well developed and fairly muscular. The hair is fair; face, lips, and gums are pale;

Digitized by Google

teeth much decayed; temperature 99·3°; appetite good; thirst not excessive; bowels regular; fæces dark (the patient has been taking iron for the last ten days). Neither the lymphatic glands nor the spleen are enlarged. There is no cardiac murmur, nor are there any signs of lung disease. The skin is pale generally. Over both legs and thighs are a number of purpuric spots, varying much in size, distribution, and colour: the spots are larger in size and more numerous over the right leg, being small between the ankle and knee and large from the knee to the groin. With the exception of a few purpuric spots over the penis, none are higher than Poupart's ligament anteriorly, and, posteriorly, a line drawn horizontally across the posterior iliac spine. There was no blood or albumen in the urine.—August 16th: The feet and legs are swollen, and, with the exception of a few small patches of healthy skin, the whole leg below the knee is of a yellowish-green colour. Yesterday (15th) the child complained of a cough, and the mother applied a poultice to the right side of the chest, and now in the situation of the poultice are a number of purpuric spots. The pain in the knees is better. Temperature 99·8°. The child continued under observation until October 1st, during which time purpuric spots came and went in regular succession; but since September 1st gradually disappeared and were gone by October 1st.

CASE 2. *Chorea in three members of the same family; complete recovery in two members; chorea followed by epilepsy in the other.*—Florence S——, aged seventeen, of no occupation (owing to her having fits), born in London, was admitted under the care of Dr. Hawkins suffering from "fits," which have occurred at intervals for the last five years. The father and mother are quite healthy. There is no history of any nervous disease or of rheumatism in any member of former generations. There are two brothers and three sisters. One brother had measles when two years old, scarlet fever when eleven; he then became quite well, and when thirteen years old he had choreic movements in both arms and legs, which continued for three months, but have never recurred since. One sister had measles when five years old, scarlet fever when six; then became quite well, and when nine years old she had choreic movements similar to the boy above mentioned, which lasted for four months, but have never recurred. Her brothers and sisters are older than the patient. There is no history of any intermarriages in the family. The house is very good, as also the food, the people being in fairly good circumstances. The patient was quite well until she was seven years old, when she had chorea; the movements were "all over the body," and she could scarcely walk. This lasted for one year, when the patient became quite well. When nine years old she had scarlet fever; she recovered completely from this and remained quite well until she was twelve years old, when she had a "fit." In the morning her brother noticed that she was dull and stupid, and appeared strange in her ways. She then, without any warning or scream, suddenly fell down and foamed at the mouth. Arms and legs moved in a jerky manner, and during the fit the patient bit her tongue and micturated. During the fit the mother noticed that the face was drawn to the left side. This, however, was not noticed after the fit had ceased. The mother cannot say how long the fit lasted, for the patient went off to sleep, and remained so for some time. For two years the patient remained well; she then had some occasional twitchings, but these disappeared, and then in twelve months after she had another fit similar to the one described. The last fit was on July 7th, 1885.

CASE 3. *Epileptic fits followed by ecchymosis (purpura).*—Isabella A——, aged thirty, married for six years, and has four children. Was admitted complaining of fits, from which she had suffered for nineteen years. To the best of the patient's knowledge there have been no intermarriages in her family, neither is there rheumatism, nor has there been any nervous disease till the present generation—one brother had convulsions when a baby, now he is quite strong and healthy; one sister had a "paralytic stroke" some years ago, but the exact date and a more accurate description cannot be obtained. The patient has never had any other illness, and she attributes her fits to a fright on leaving home when eleven years old. A description of the fits at this time cannot be given with any accuracy; they occurred about two in a year. The patient began to menstruate at fourteen; this made no alteration in the fits. At twenty-four she was married, and after the birth of her first child the fits became more frequent, having had two in the first two months after the birth of her child, which she did not nurse. In thirteen months after the first child was born she had her second child; while carrying the child no fits occurred, but soon after the child was born she again began having fits. In one year and seven months after the birth of the second child she gave birth to another, and the fits were absent while carrying the child; soon after its birth the fits began to occur. In two years after the birth of the third child, another was born; this last is now four months old, and since its birth the patient has had three fits in six weeks. The following is a description of the fits from which the patient is now suffering. For about two weeks previous to the fit the patient noticed that her memory became bad, and a few days before the fit she had headache, and there was a feeling of swelling and bursting in both head and neck. Then, without any other warning, and usually at night, what the sister describes as a "strange" noise is made, and if standing or sitting the patient then falls, clenches her hands and her teeth, fixes her eyes, moves her arms in a jerky way, and bites her tongue; this last for two or three minutes, according to the idea of time of the sister who lives with her. After the fit, on first seeing any person, she always has the sensation of "dying," and for some days afterwards, when placing her hands in cold water, she feels as if touching ice. After the fit the patient has what she calls "blood spots" come out on the face, equally on both sides of the face, but only on the left side of the neck; these have shown themselves as long as the patient can remember, and they appear to be in proportion to the severity of the fit. On one occasion (a very bad fit) the patient, in falling, cut her nose, which bled very much; the spots were then very few in number, and the patient got over the feelings which she always has while in a fit quicker than usual. The spots usually disappear in a week or ten days. Eight years ago the patient micturated in a fit, but has not done so since.

Remarks by Dr. HAWKINS.—While there is nothing original to be mentioned in connexion with the above cases, they appear to be interesting not only in themselves but also taken as a series, for we have chorea followed by purpura, then chorea followed by epilepsy, and thirdly, epilepsy followed by ecchymosis. Taken separately, Case 1 is interesting from many points, but I will merely allude to the fact that there were choreic movements present for eighty-nine days, followed by complete recovery for 101 days, and then pains in the knee-joints and purpura manifested themselves, and continued for 105 days. While there is no history of rheumatism in the parents or other members of the family, we must, I think, regard the case as one of chorea and rheumatism, and it may be questioned whether it is always necessary to have the evidence of rheumatism to prove that the cause of chorea is similar to that which causes it when rheumatism is present. Indeed, lately I have been frequently asking myself whether rheumatism, heart disease, chorea, epilepsy, asthma, and phthisis are not merely different outward manifestations of a common basis, just as one soil, if left to itself, brings forth a variety of weeds differing from each other and yet peculiar to that kind of soil; but I must not enter into this at present. The fact of purpura occurring so soon after choreic movements suggests to one the question whether in this case a similar condition—in fact, a purpura of some parts of the nervous system—occurred and caused chorea? Case 2 is interesting in chorea having occurred in three members of the same family, recovering completely in two members, while in the third it was followed by epilepsy. And it appears to me worthy of notice that, in the two cases in which recovery took place, measles and scarlet fever occurred prior to the chorea, while in the third case there was scarlet fever afterwards, while she has never had measles. Case 3, while including no special point of particular interest taken by itself, yet taken with the foregoing cases it is interesting from the fact of an ecchymosis somewhat similar to the purpura occurring after the fits, and lasting ten days. Trousseau, Van Swieten, and others speak of the occurrence of ecchymosis after fits as being very common; while Trousseau found the ecchymosis, which lasted for so long a time as ten days, usually occurred in cases of paralysis after epilepsy; but in this case there was no paralysis, and the main interest is that we have chorea followed by purpura in 101 days, and we have an epileptic fit followed immediately by ecchymosis. Can we, then, trace any relation between the causation of these two diseases?

NORTH STAFFORDSHIRE INFIRMARY.

TUMOUR OF SPERMATIC CORD SIMULATING HERNIA, CAUSING SLOUGHING OF SCROTUM; OPERATION; CURE.

(Under the care of Mr. SPANTON.)

FOR the notes of the following case we are indebted to Mr. R. Cann, assistant house-surgeon.

Isaac G——, aged fifteen, residing at Hanley, apprentice potter, was admitted into the North Staffordshire Infirmary on July 14th, 1885. The patient, a strong healthy boy, had observed some months before admission a swelling in the right groin, sometimes reaching into the scrotum, at others passing up the inguinal canal out of sight. The tumour had all the usual characters of an omental hernia, was evidently solid, passed into the inguinal canal when gently pressed up, and descended on coughing or straining. It was apparently attached to the spermatic cord. For some time this remained in much the same condition, causing no trouble, until one day, a few weeks before admission, sickness came on, with great pain in the neighbourhood of the tumour, and constipation. Added to this the tumour could not be reduced as formerly. The scrotum became œdematous, the induration around the cord increased, and everything seemed to indicate an inflamed and strangulated omental hernia. He was advised to go to the infirmary for operation. On admission the right side of the scrotum was inflamed and œdematous; the testicle could not be felt. Under chloroform Mr. Spanton made an incision over the right spermatic cord, and the subcutaneous tissue was found sloughy for some distance. On dissecting this away, a hard firm mass occupying the position of the cord came into view, extending up to the external abdominal ring, about two inches in length, and about the size and shape of a large pigeon's egg. A ligature was applied as high up as possible on the cord, and the whole mass with the right testis dissected away. Sublimate gauze dressing and silver wire sutures were used, and the wound rapidly healed. The growth, when cut into, was of almost cartilaginous hardness, and consisted of dense connective tissue. So long as it was small enough to slide up and down the inguinal canal it caused no trouble; but as soon as the inflammatory swelling occurred in and around it, the vessels in the cord were so much compressed as no doubt to interfere with the vitality of the parts below, and hence led to the rapid sloughing which took place. The case is one more illustration of the wisdom of the old maxim, "When in doubt, operate."

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Aneurysm of Innominate Artery.—Chronic Poisoning by Bisulphide of Carbon.

The last ordinary meeting of the year of this Society was held on the 21st ult., Dr. W. M. Ord, President, in the chair.

Dr. B. W. RICHARDSON read a paper on a case of Aneurysm of the Innominate Artery. The aneurysm was of the dissecting variety. The external indications of the aneurysm were remarkably variable. The patient was a woman aged sixty-two, in whose personal and family history there was but little that had any bearing on her final history. Twelve years ago she had suffered from an abscess of the antrum, for which surgical treatment was sought. In October, 1884, a large pulsating tumour the size of an orange was found in the right infra-clavicular region. The right radial pulse was feeble; there was a systolic bruit, but no thoracic symptoms. The patient was ordered absolute rest, and she was not heard of again till May of the present year, when the pulsating tumour had disappeared, and the patient declared that she was quite cured. There was, however, dulness, a systolic bruit, and a small pulse on the right side. In June three pulsating tumours had appeared: one was situate above the clavicle, and two below that bone; the inner one was over the sternum. The tumours pulsated synchronously, and with the right radial artery. By September the outermost tumour below the clavicle had subsided under the influence of complete rest. From this time onward the patient was carefully watched. On October 23th, blood escaped from two small openings in minute quantities. Cotton-wool soaked with perchloride of iron formed a protective covering. A few days later a large opening had formed which measured three-quarters of an inch long and half an inch across, and was blocked by clotted blood. The patient died, without a struggle, hæmorrhage, or pain, on November 30th. The parts concerned were preserved in vapour of ammonia in a box, to which Dr. Richardson drew special attention. The aneurysm springing from the arch of the aorta caused absorption of bone of the first and second ribs and inner end of the clavicle. The tumour had pressed on the œsophagus, and displaced it to the left. There were grooves in the last two cervical and first dorsal vertebræ due to absorption of bone. The chief sac was filled with laminated fibrin. There were two pouches; one that followed the course of the right common carotid, and the other from which the blood came. No exciting or predisposing cause could be made out. The patient had suffered in early life from a goitre, and there might be some kind of relation between that goitre and the occurrence of aneurysm. The absence of dyspnœa, dysphagia, and other symptoms of pressure on the various organs included within the thorax was commented on. The long continuance of life was remarkable, since the only separation between life and death lay in the thin covering that protected the opening into the aneurysm.—Dr. Low remarked on the interest of the clinical and anatomical features of the case. He considered that retrocession of an aneurysmal tumour was a sign that lamination of the blood-clot had occurred.—Dr. DE HAVILLAND HALL spoke of the beneficial effect of very large doses of iodide of potassium combined with rest and strict limitation in the quantity of fluids taken. In reply to the President, he said he could not explain the mode of action of iodide of potassium.—Dr. ANGEL MONEY admitted the immense value of iodide of potassium, and thought its mode of action was probably of a sedative and depressant nature.—Dr. W. B. HADDEN was very sceptical of the action of iodide of potassium in aneurysm.—Mr. W. ADAMS remarked on the atheromatous state of the ascending arch of the aorta.—Dr. KINGSTON FOWLER had no doubt of the value of iodide of potassium in the treatment of aneurysm.—Dr. ORD asked for information as to the reasons for regarding the aneurysm as dissecting in nature. Iodide of potassium was useful probably because syphilis was frequently operative in the production of aneurysm; moreover, it had a remarkable power of absorbing inflammatory deposits.—Dr. RICHARDSON, in reply, said he was not sure that the subclavian artery was completely blocked. He had given iodide of potassium on Balfour's plan, and not with any idea that syphilis had been in existence. He thought the mode of action of iodide of potassium was still doubtful. He considered that we could by means of the sphygmograph distinguish an aneurysmal tumour from one which pulsated merely by contact with an artery. The aneurysm was not really "dissecting" but "wandering" in kind.

Dr. W. B. HADDEN read a paper on a case of Chronic Poisoning by Bisulphide of Carbon. The patient was a man aged forty-five, who was employed at an indiarubber factory, where he had to inhale the vapour of bisulphide of carbon and chloride of sulphur. The main symptoms were loss of power over the extremities, with a tendency to stagger and incoördination generally. He had no defect of vision. His fellow-workman had also been under treatment at St. Thomas's Hospital with general muscular weakness and visual defect with colour-blindness. The case was reported in the Ophthalmological Transactions, vol. v., in which the report of the Special Committee would also be found.—Dr. RICHARDSON said that pure bisulphide of carbon was a powerful anæsthetic, and caused painless death. He had frequently used it to destroy dogs. Delpech, in 1866, was the first to describe the effects of chronic poisoning by this agent. This form of poisoning was more common in France, but even there it had diminished with improved hygiene of the workshops.

ACADEMY OF MEDICINE IN IRELAND.

Double Fœtal Monster.—Recent Progress in Obstetric and Gynæcological Medicine.—Axis Traction in Instrumental Delivery.—Fibro-myomatous Polypus.

AT the meeting of the Obstetrical Section on November 27th, 1885,

Dr. KIDD showed a Double Fœtal Monster, aged about five months, which had been forwarded to him by Dr.

Digitized by Google

Keeper of Armagh. The specimen had been retained in utero for some time after its death, and upon delivery was already somewhat lacerated and decomposed. There were four upper and four lower limbs, and a single head. Two completely formed bodies were united to one another along the line of the sternum and the anterior abdominal wall, and a single funis was attached to the lower part of the abdominal wall. It was therefore one of the most common forms of a double monster. For very many years the formation of such monsters had puzzled pathologists—some affirming that they originated in the partial cohesion of separate embryos, thus indicating duplicity tending towards unity; and others affirming, on the contrary, that they resulted from the double formation of individual parts in a single embryo, being thus the expression rather of unity tending towards duplicity. The researches of Dr. Allen Thomson had settled this question in favour of the latter hypothesis, which was now the theory almost universally believed to be the true one.

The President of the Section, Dr. T. MORE MADDEN, then delivered his opening address on "Recent Progress in Obstetric and Gynæcological Medicine." He said: "The consideration of those points in the history of the recent developments of obstetric and gynæcological science on which I shall venture to address you this evening will supply much reason for congratulation on the modern advancement and present position of these twin sciences, as well as solid ground for hope in their still greater progress in the near future. Thus, for instance, childbirth has been largely divested of its former sufferings and dangers. By the more general employment of anæsthetics the throes of labour have been rendered endurable. By the earlier and more judicious use of the forceps, and the other recently improved methods of affording assistance in all cases of difficult parturition, the duration and risks of that formerly too often protracted period of agony and danger have been diminished. By the aid of the means now available for the prevention and treatment of post-partum hæmorrhage, that cause of obstetric mortality has been almost completely removed. By those antiseptic prophylactic measures now taken for obviating puerperal fever, the occurrence of that whilom most frequent and most serious of the dangers consequent on childbirth has been strikingly lessened. If, however, as still may happen, notwithstanding these precautions, septicæmic puerperal disorder should supervene, we are now armed with effective and rational therapeutic resources for its treatment, and are no longer, as of old, in the position of helpless spectators of the irresistible course of disease to an inevitably fatal termination. Lastly, by the general substitution of version, the induction of premature delivery, and other methods of practice compatible with the safety of both mother and child, in cases where formerly embryoplastic operations were unhesitatingly, and too often recklessly, resorted to, the proportion of cases in which such procedures are now employed has become so minimised as to lead to a confident expectation that in the still more perfect midwifery practice of a not distant future the great objects of obstetric science—viz., the delivery of living children with safety to their mothers—will be yet more generally realised than even at the present time is the case. This expectation is fully justified by the steady annual diminution of late years in the mortality of childbirth and the puerperal state, as recorded in the successive reports of the Registrar-General. Thus, in the ten years from 1861 to 1870, the deaths from childbirth and puerperal fever in England and Wales averaged 60 in every 100,000 women living between the ages of twenty and fifty-five; whilst during the five years from 1876 to 1880 they fell to 53 in the same number. Not many years have elapsed since it was estimated by Dr. Matthews Duncan that the average mortality in connexion with childbirth in these countries was something like 1 in every 120 women confined. Now, if we turn to the most recent report of the Registrar-General—that issued this year,—we find that in 1883 the maternal death-rate in England and Wales from all causes in connexion with parturition was about 1 in 230 births. In the Dublin Lying-in Hospital the same happy result of modern science is equally well proved. Thus, in the seven years which ended in 1864 there were 8224 births in the Rotunda Hospital, with 252 maternal deaths, or 1 in 32; whilst in the same institution, according to the recent report of the Board of Superintendence, the total last year was 1148 and only 9 maternal deaths, or 1 in 122. And finally, from the report of the Irish Registrar-General we learn that the death-rate from puerperal fever in this country last year was only 300, being 70 below the average mortality from the same cause during the preceding ten years. In the discovery and practical application of the various improvements in obstetric art which have so happily conduced to its advance, and to the saving of life and diminution of suffering thereby, the Dublin School of Midwifery has taken a foremost part ever since the foundation, 140 years ago, by Bartholomew Moss, in this city, of the first British lying-in hospital. And as the credit of some of these improvements has been claimed by recent authorities in Germany, France, and elsewhere, I may remind the Academy that it was here that the practice of delivery by version as a substitute for craniotomy in cases of pelvic contraction was first suggested by Dease, and revived by M'Clintock: it was here that by Beatty and Johnson the advantages of the timely, judicious, and more frequent use of the forceps were earliest recognised and demonstrated; it was here that the method of following down the uterus for the prevention of hæmorrhage and for the expulsion of the placenta, with which the name of a modern German authority is now incorrectly associated, was first introduced by M'Clintock, and has been carried into effect by every obstetrician educated in the Dublin School for a century before the birth of Steele. It was in this city that the so-called modern methods of obviating perineal laceration and of their immediate reparative treatment were first suggested and have been since constantly acted on. Turning now to the second of the two branches of medicine with which this section of our Academy is especially concerned, it will be apparent that, remarkable as has been the recent progress of the obstetric art, still more wondrous has been the contemporaneous development of gynæcology. To illustrate the recent change which has taken place in this department of medical practice I shall briefly contrast the imperfect diagnosis and unsatisfactory treatment of various utero-ovarian diseases some twenty years since with the results now attained by the modern science by which the defective gynæcological knowledge that then prevailed has been so happily replaced. At that time the cavity of the living uterus was a sealed book—a *terra incognita* to uterine specialists then unprovided with any efficient means for exploring its condition, or with any trustworthy method of dealing with those intra-uterine disorders which, thanks to the procedures suggested by Hagar, Kidd, Atthill, and Ringland, may now be easily recognised and effectually treated. In the pre-antiseptic surgical period to which I refer it would obviously have been impossible to foresee the successful results which in so many instances are now attained in the removal by abdominal section of ovarian and uterine tumours and other intra-peritoneal and pelvic morbid conditions. Nor was it merely subperitoneal tumours that were then generally looked on as being outside the range of operative assistance; those interstitial and intra-uterine submucous fibro-myomata which are successfully treated by every modern gynæcologist were, only twenty years since, too commonly regarded as beyond the possibility of removal. In those days, too, the reparative treatment of vesico-vaginal fistula was more frequently a failure than a success; and, notwithstanding that Simpson had previously done much to prove their curability, it was not until the subsequent adoption of the variously modified plastic operations introduced by Marion Sims, Bozeman, Goodell, and, above all, Emmet, that women suffering from extensive disruptions of the vesico-vaginal walls ceased to be abandoned to lives of hapless misery. Fifteen years ago, when attention was recalled to this subject, the pathological importance and frequency of uterine displacements were unrecognised, and their treatment remained unsatisfactory. In the same way the physiology and pathology of menstruation have only of late become understood as the result of the labours of Williams and Wiltshire; the management of its abnormalities was previously largely empirical. The bearing of cervical laceration on pelvic disorders was ignored until the subject was elucidated by Emmet. Lastly, many of the morbid conditions of the uterine appendages, such as salpingitis, pyo-salpinx, and hydro-salpinx, to which so much importance is now attached, were wholly unknown in the student days of the majority of those I have now the honour of addressing."

Dr. NEVILLE detailed the various instruments by which it had been attempted to give effect to the principle of Axis

Traction in Instrumental Delivery. To Tarnier should be given the credit not only of having exposed with freshness and clearness the defects of the ordinary forceps, but also of having been the first to construct one which answered to the true demands of theory. The main defects of Tarnier's most recent model consisted in its complexity, amounting to clumsiness, and its cost, which is prohibitive to a general practitioner. Some of the chief modifications of Tarnier's forceps were exhibited and explained, Professor Simpson's being that best known in this country. The alleged advantages and defects of these instruments were critically considered, the true requirements being stated to be that the forceps should be constructed so as to allow of the whole force employed being exerted in the axis of delivery, and so as to leave the spontaneous movements of the head uninterfered with. So far as the author knew, all those who had hitherto devised a true axis-traction forceps had adopted Tarnier's plan of using steel traction rods, permanently attached by pivot joints just below the fenestræ of the blades. Yet such rods were certainly open to many objections which would make it very desirable, if the same results could be otherwise attained, to do without them. They add to the cost and complexity of the instrument, make it more difficult to introduce, prevent the shanks being passed well back towards the perineum without danger of injuring it during delivery, and introduce the chief difficulty in all these forceps—that of securing them in some neat and effective manner to the rest of the traction apparatus. The forceps which he exhibited was without such traction rods, but he had the very high scientific sanction of Mr. G. F. Fitzgerald, F.T.C.D., for stating that mechanically it gave the same results in another way. The forceps to which the traction apparatus is applied may be Barnes', Simpson's, or other double-curved forceps, according to individual preference; but the author on many accounts preferred the first-named. Immediately beneath the lock a curved steel bar is fastened rigidly to the handles, and projects backwards sufficiently far to reach the imaginary continuation of the axis of the blades. At this point a pivot joint, admitting of free motion in the horizontal plane of the forceps, connects the traction bar with another short one which terminates in a joint so arranged as to permit motion in a plane perpendicular to that allowed by the first joint. From this point the traction apparatus is continued onwards into a transverse traction handle, with which it is connected, exactly as in Simpson's axis-traction forceps, by a rotatory joint. The advantages claimed by the author for this instrument were that it is much simpler, cheaper, more portable, and easier of application than any of the modifications of Tarnier's forceps, while possessing all their merits; that it gets rid of the disadvantages of traction rods within the vagina; that the traction apparatus consists of one piece, which can be immediately applied after the blades have been locked; and that the same instrument may, by means of this apparatus, serve either as an axis traction or an ordinary double-curved forceps.—Dr. MACAN thought Dr. Neville gave too much credit to Dr. Tarnier and too little to Hubert, Hermann, and others, who had been working at the same problem of axis traction before him. He did not attribute the same importance as Dr. Neville did to the special construction of Tarnier's forceps allowing of rotation, because he believed that rotation could, and often did, occur within the blades of the forceps without their partaking in it. He had himself used Dr. Neville's forceps in several cases in the Rotunda Hospital, and found it answer extremely well. The elimination of traction rods he considered an immense improvement, and the ease with which the traction apparatus could be applied, as well as its portability, were distinct improvements. It would be an advantage if it had some kind of indicator which would show the exact direction in which to apply traction.—Dr. ATTHILL said that the instrument devised by Dr. Neville appeared to him to be the best and simplest axis traction forceps he had yet seen. He was not, however, an advocate of axis-traction forceps. He objected to the compression screw, which seemed a necessary part of them all. It might cause such a pressure on the child's head that death would follow. He had used Tarnier's first model when he was Master of the Rotunda, but founded it so complicated and difficult to apply when the head was above the brim that he had abandoned it.—The PRESIDENT doubted whether axis traction would long continue to be practised. Tarnier's instrument he considered entirely too complicated.

Dr. KIRKPATRICK exhibited a Fibro-myomatous Polypus removed from a multiparous woman in Sir P. Dun's Hospital. The patient had been suffering from symptoms of a uterine tumour for over two years, and of late had frequently had alarming hæmorrhages. The tumour had several times protruded from the vagina, and had been replaced by the patient herself. When about to remove the polypus he had found it separated by a very distinct pedicle from a completely inverted uterus. He removed it with an écraseur, and some vessels were tied in the stump, which was afterwards seared with an actual cautery. He had not since had an opportunity of examining the parts. The tumour, examined microscopically by Dr. H. Bewley, proved to be most unusually vascular.

Dr. MACAN showed a somewhat similar Polypus removed from a patient under his care in the Rotunda Hospital. He also exhibited an eight months' fœtus with general anasarca and curious folds on the skin.

Reviews and Notices of Books.

The Principles and Practice of Medicine. By the late CHARLES HILTON FAGGE, M.D., F.R.C.P. Two vols. London: J. and A. Churchill. 1886.

[FIRST NOTICE.]

FEW works have issued from the medical press of late years which will receive a more hearty welcome than the one before us; and deeply as we deplore the fact that he who wrote it is no longer with us to accept the reward of his labour, it must be a source of gratification and solace to his wide circle of friends to feel that they possess in these writings the sum of his learning and experience. It is true that, knowing how ardently he devoted himself to medical science, much has been expected from him in this long-looked-for work; but we venture to think that it will fully come up to these expectations. We do not mean to say that it is free from defects, or that its author would himself have felt satisfied with it, for we are told in the preface how great was the care he expended in writing and rewriting it, so as to render it as complete as possible. A perusal of its pages shows that it is one of the most scientific and philosophical works of its kind, being in truth a mine of clinical and pathological facts, which are dealt with in so masterly a manner that we know not which to admire most—the patient labour and thought expended in bringing them to light, the learning and acumen that illustrate them, or the calm and judicial spirit in which they are estimated and criticised.

It would be an impossible task within the limits of a review such as this to convey an adequate idea of the contents of these volumes; and we must fain be content with such an outline as will, we hope, excite the desire of our readers to study the work for themselves. The introductory chapter contains, in the remarks upon the essential features of diseases, the principles upon which a nosology should be based, and the true light in which so-called "predisposition" should be regarded as an etiological factor, that stamp of independence and freedom of thought which characterises the whole book. It is this which will make it so highly valued, for it not only gives to it an abiding interest, but serves to stimulate thought in the reader by presenting him with facts in a new light. Again, in the same chapter there is an extended discussion upon the modes of dying which deals with the matter in a far more rational way than is met with in text-books. Bichat's triune division has done service so long that it is refreshing to find it clearly demonstrated that it is incorrect, and that, strictly speaking, there are only two distinct modes of dying—viz., by the lungs and by the heart. Under the former head Dr. Fagge distinguishes between arrest of respiration by sudden paralysis of the respiratory centre in

Digitized by Google

the medulla, and the more gradual process of asphyxia, a distinction which is strictly true, but seldom fully recognised; whilst death by failure of the heart's action may be sudden, from cardiac paralysis or spasm, or "shock" producing fatal inhibition, or more gradual, as in syncope, or from hæmorrhage or collapse. At the same time there remains that exceptional form of death which may almost be termed "natural," where "all the vital functions are brought to so low an ebb before any one of them is absolutely arrested, that to determine the order in which their ultimate extinction takes place is superfluous, even if it be not impossible." The subject of Contagion is next discussed, the definition of *specific* diseases being "those diseases which have a definite cause arising from without, but acting within the body, distinct from the causes of all other diseases," and the classification of such diseases into—(1) miasmatic, (2) contagious, and (3) miasmatic-contagious, is adopted. The germ theory and the part played by microzymes in infection are adequately discussed, the evidence in favour of a *de novo* origin of infective disease being held to be insufficient. The remarkable fact of acquired immunity is assumed to be due to the blood or tissues undergoing such a change in the course of the disease as to no longer afford the conditions requisite for the development of the special microzyme; and it is pointed out that otherwise an individual might constantly reinfect himself. As regards protective measures, Dr. Fagge points out the inutility of measures of quarantine, doubting even if it be right to speak of the diseases as "preventable"; but he looks forward to a future in "vaccination," going so far as to say, "One could not render a greater service to humanity than by discovering how to transmit the contagion of scarlet fever through any of the lower animals in such a way that when reintroduced into the human subject it should carry protection without risk. I am not sure whether it might not be well to expose children on purpose to infection from this disease, when it happens to be epidemic in a mild form." Although the tendency of modern investigation does, indeed, point in this direction, we confess to be unwilling to contemplate the extension of protective inoculations with equanimity; and rather hope, before the time arrives when the "attenuated virus" of each of the contagious diseases shall have been isolated, that some other, but equally efficacious, method of its introduction into the system shall be discovered. The modes of entrance of contagion into the body are next discussed, Naegeli's views being for the most part accepted, and the chapter concludes with some practical directions upon disinfection.

The interesting problem of Fever forms the next chapter, opening with some observations upon clinical thermometry. Liebermeister's doctrine of pyrexia is accepted to the effect that pyrexia follows the same laws as the physiological regulation of the heat of the body, only that there is an alteration of the point at which this regulation is set. The subjects of Inflammation, Tubercle, and Tumours are, as can well be imagined, treated by the author in a manner which will be sure to attract attention, for, as a pathologist, Dr. Fagge had earned a high reputation. He adopts Cohnheim's doctrines upon inflammation, but with an important addition, in the view that the damaged cells of the injured part are removed by the exuded leucocytes. This view, he points out, was substantially held by Goodsir, and it makes of the inflammatory process something more than a merely physical effect of damage to vessel walls. In speaking of the various inflammatory exudations, Dr. Fagge shows how different the catarrhal is from the fibrinous, owing to the great production of epithelial cells, probably from the increase of pabulum; and he suggests that the absence of fibrinogen in pus may be due to the leucocytes using up that material for nutriment. That croupous and diphtheritic exudations depend upon local death of the epithelium and tissue upon which they occur, as believed by Cohnheim, is apparently accepted by Dr. Fagge, who, however, points out that no one has yet suggested that the endothelium of a serous cavity must die before plastic lymph can form upon it, which logically should follow Cohnheim's explanation of fibrinous deposits—viz., that exudations do not coagulate within living tissues. Upon the subject of Tubercle, Dr. Fagge says that he has always been in accord with Laennec's teaching, which says much for his clearness of vision; for since Laennec's time we have witnessed a widespread tendency against these views, culminating in a no less remarkable reaction towards them. Dr. Fagge, perhaps rightly, assigns much of the waywardness of doctrine to the histologists, and asserts, *inter alia*, that a fictitious importance has been given to the giant-cell. His own view is explicit enough, for he believes that "tubercle" is a modification of the inflammatory process due to a special irritant, and therefore he sees no difficulty in accepting epithelial proliferations as well as granulation tumours as tubercular according to the nature of the tissue exposed to the irritant. It is needless therefore to remark that he is a strong upholder of the doctrine of the unity of phthisis, and even would admit as tubercular such destructive lung disease as occurs in those exposed to the inhalation of dust. He finds also in the discovery of the tubercle bacillus a confirmation of those views, for it supplies the missing link in the chain of evidence that there is a specific irritant at the root of all tubercular processes. It is interesting to read his criticism upon the earlier work on "artificial tubercle," where he foretells with accuracy the fallacies, since admitted, that underlie such inoculation experiments with non-tubercular substances. He doubts the possibility of distinguishing bovine tuberculosis from the human disease; and the fact that the bacillus is found in both goes far to substantiate this. Nevertheless, he hesitates to accept the doctrine of contagion of tubercle from without, seeing how scanty is the clinical evidence in support of it. We must confess that the alternative with which he presents us is not very satisfactory, especially in view of the doubts thrown upon Buchner's once famous discovery of the conversion of a pathogenic into a non-pathogenic bacillus. Dr. Fagge, after speaking of the difficulties associated with accepting either the view that the tubercle bacillus is constantly finding access to the body, and only implanting itself when the tissues have their local resistance lessened by inflammation, or the other view that the bacillus may remain long latent in the body until some accidental circumstance calls it forth into activity, goes on to say: "It seems to me there is a third possibility—viz., that under certain unknown conditions the occurrence of what is at first a simple inflammatory process may cause microzymes, already existing in the body, to acquire specific properties that they did not previously possess, and to convert the simple inflammation into a tuberculous one. For this hypothesis there are abundant analogies among the acute infective inflammations." The chapter on Tumours calls for little remark; it is a thoroughly scientific review of the subject, and among its more interesting and original contributions are the details of cases of multiple sarcoma, and the bold attempt to transfer the term epithelioma to its more appropriate place as significant of all epithelial new formations, and to consider carcinoma to include the following varieties: (*a*) simple; (*b*) keratoid—i.e., "squamous epithelioma" of writers; (*c*) columnar. Cohnheim's doctrine of embryonic relics being the starting-point of new growths, is held to be inapplicable universally, although it is manifest that Dr. Fagge believed that the generalisation contains probably a good deal of truth.

Passing from these preliminary chapters, the descriptions of diseases open with one upon Syphilis. It contains an

Digitized by Google

impartial discussion upon the question of the nature of the soft chancre, and the opinion is expressed that one commonly sees mixed forms of the combined local and infective sore, the suggestion being further made that the ulcerative process in the former may in some cases destroy the syphilitic virus which has been inoculated at the same time. The description of the syphilides is excellent; and throughout the article it is obvious how careful has been the study of the writings of Hutchinson and other syphilographers. It is interesting to note that Dr. Fagge expresses some doubt as to the fibrous testis being an unequivocal sign of previous syphilis, for it often happens that this is the only lesion present in the body. In the section on congenital syphilis we note that cranio-tabes is regarded as being due to concomitant rickets. Each of the specific diseases is then discussed in turn, especial prominence being given to their etiology and pathology. The *de novo* origin of enteric fever is rejected, and it is pointed out with full illustration that the virus of this disease can be communicated in four different ways—viz., by aerial infection, by drinking-water, by milk, and by meat. Irvine's views upon the relapse of enteric fever are stated. But in this—as, indeed, in each of the articles devoted to the infective diseases—the section on treatment is somewhat inadequate. Antipyretic methods are referred to, but hardly discussed; whilst as regards such affections as scarlet fever and small-pox, the details of treatment are decidedly deficient. The article on Rötheln is devoted to a criticism upon prevailing views, in which discrepancies are prominently brought into view, and the conclusion arrived at is that the evidence is not sufficient to warrant its being regarded as an independent affection. In Dr. Fagge's opinion, rötheln is only an ill developed or anomalous form of measles, and he does not consider this view invalidated by the occasional supervention of a second attack of measles in the individual. Ague, erysipelas, and diphtheria are dealt with in an admirable manner; and as regards diphtheria, Dr. Fagge asserts that a primary laryngeal affection is rare, for, in his opinion, this disease is not identical with sporadic membranous croup. The etiology of cholera is illustrated by the evidence afforded in the epidemics in this country. It is held that Pettenkofer's "ground-water" theory, ingenious as it is, requires more proof before it can be accepted; whilst, at the same time, it does not (when modified by Naegeli's hypothesis) negative the occurrence of direct contagion, which Dr. Fagge thinks sometimes indubitably occurs. The two years that have elapsed since the author's death have, as we all know, revived the cholera question with renewed intensity; but although, in consequence, this book contains no discussion upon the comma bacillus, its perusal shows how very little we have really advanced beyond the position arrived at when Dr. Fagge wrote.

Eminent Doctors; their Lives and their Work. By G. T. BETTANY, M.A., B.Sc. Lond., F.L.S. In Two Volumes. London: John Hogg.

BIOGRAPHY is a branch of literature or of knowledge which every wise man will cultivate alike for the pleasure and for the instruction which it yields. The true remedy for much of the poor trashy reading which we see, and the poorer lives which so many of us lead, is in good sound conscientious biography. At a season like this especially it is valuable, and we do not know that any wise father designing a good Christmas present to his son could do better than give him the book which we are now noticing. If both the father and son be of the great medical calling, so much the more appropriate will be the present; but we should by no means restrict our suggestion within such limits. Medical science is becoming every day a thing with which every intelligent man should become more familiar, both because it is a part of the great field of true science, and because of its enormous human interest. Besides, in any selected group of members of our profession, such as are included in these volumes—numbering about fifty-six—it is impossible not to be struck with the force and variety of character in one direction or another of a profession which includes Sydenham and Jenner, Liston and Corrigan, Cullen and the Hunters, Stokes and Alison, Parkes and Simon, Paget and Lister. It is one good feature of these volumes that they are not written by a medical man, but by one who views medical work from a scientific standpoint. Such a writer may occasionally be at fault, and may fail to observe points which a medical critic would regard as important, but there is an advantage in seeing ourselves as "others" see us, and that advantage we have in these volumes, which we have perused with much interest.

We do not always approve of the selection of the lives. There are some great omissions—as, for example, the life of Professor Alison, who, though incidentally noticed as the influential teacher of Williams, Stokes, Watson, and others, and characterised by so high a judge as Stokes as "the best man I ever knew," is not honoured with a special chapter. Amongst other conspicuous omissions which occur to us is that of Dr. Fothergill, who was an admirable representative of the profession in the last century, both in medical and public respects. It would be possible, too, to criticise the author in regard to his selection of living members of the profession. The book would have been very much less valuable and interesting than it is if he had excluded living medical men, who, it is gratifying to think, have carried the torch of truth far beyond the point at which they received it. But it would be difficult to justify all the author's living selections, and one or two of the gentlemen honoured with a biography would certainly have suffered nothing by waiting a little longer to see their literary portrait. But the book is worthy of much praise and careful reading. Men of all schools will find their heroes recognised. Certainly the Edinburgh school has no right to complain, for the chapters on the Munros, Cullen, the Gregorys, and John Bell are among the best in the book; and the enormous influence of the Hunters on the London school, and of the Edinburgh University on the last generation of London teachers—Cooper, Abernethy, Williams, Bright, Addison, Marshall Hall, &c.—is well brought out. Though we have questioned the ripeness of two or three lives selected for notice, we repeat that there are chapters on living leaders—notably those on Paget, Wells, Lister, and Jenner—that are very well worthy of the study of all the members of the profession, and of the public too. The chapters are not only entertaining reading, but suggestive. The enormous industry of our leading men is well shown. The heroes of medicine are not all saints, though in most of them there is that deep reverence which is far removed from the atheism with which we are too often credited by superficial people; but they have their faults and their quarrels and jealousies, which are not spared in these volumes. Those of the Edinburgh school especially are faithfully reproduced, and show how a sort of Billingsgate corner often exists in the greatest minds. There was one even in Milton. It is gratifying to believe that this corner of great minds becomes more and more attenuated both in Edinburgh and London, and doubtless elsewhere, under the influence of larger truth and widening temper. We must not trust ourselves to go into minute notices of individual lives. We are grateful to Mr. Bettany for reproducing from our own columns almost forgotten passages of forecast, which it is pleasant to us to see again. His book shows well the great problems of science and humanity with which our profession has to deal, and is dealing, with ever-increasing effect.

Medical Book-keeping.—MR. C. M. KEMPE, Chantry House, New Shoreham, sends us specimen pages for the General Practitioners' Visiting List, Journal, Almanack, and Memorandum Book, which is said to facilitate posting. The signs look a little complicated, but the plan seems calculated to save time and trouble. The author alleges that the posting into a ledger of a large practice can be done "in four or five hours a month." The forms are published by Silverlock, 22, Blackfriars-road, S.E.

Diaries, &c.—MESSRS. LETTS and Co.'s series of Memorandum Books, Diaries, Account Books, &c. for 1886 exhibit their usual excellence. They are of all sizes, and are made to suit the convenience of professional and commercial men in the various details of their work. It is difficult to conceive how the onerous duties of medical practitioners could in these days be carried out without the aid afforded by such books as those under notice.

New Inventions.

SWAIN'S EMERGENCY TRACHEOTOMY CASE.

THERE are few operations in surgery which the practitioner is more frequently called upon to perform in a hurry than tracheotomy. The hospital surgeon, the busy general practitioner in town, or the country doctor remote from all help, may suddenly be required to open a windpipe when the loss of moments may involve the sacrifice of life. As a rule, the best provided surgeon, when so called, rushes to his instrument cabinet. He picks out a tube here, a box of scalpels there, retractors in another place, and in the end gets to his case with perhaps something of importance left behind. Mr. Paul Swain has therefore conferred a benefit on the profession at large in having caused Messrs. Meyer and Meltzer to construct a tracheotomy case which appears to contain every possible requirement for the operation The following are the contents of the case, and are mentioned as nearly as possible in the order in which the various instruments are used in the course of the operation; 1. Two scalpels. 2. Two double-pronged blunt retractors. 3. Pair of blunt-pointed scissors. 4. Two pairs of ordinary dressing forceps. 5. Sharp hook. 6. A scissor-shaped

dilator. 7. Three tracheotomy tubes, of Parker's pattern. 8. Pair of artery forceps. 9. Dilator to be retained in trachea in cases in which a foreign body remains impacted. All these instruments are fitted into a tray, whilst underneath is Parker's suction instrument for removing blood or false membrane. There is also a place for ligatures, tape, needles, &c. The whole is contained in a strong, neat, unpolished mahogany box.

A NEW BED-LIFT.

DR. BATSFORD, of St. John's, New Brunswick, forwards [illegible] adapted for the lifting of patients, in order to examine the head and other purposes. It consists of a framework the size of the bed or mattress, the sides of which are made of wooden bars, and the end pieces of plate iron an inch and a half wide and three-sixteenths of an inch in thickness, pivoting in the centre. These are so contrived that when the lift is placed on the bed the framework falls on each side, the canvas is slackened, and the patient rests on the mattress or bed provided for him; but when the framework is lifted a catch prevents the pivot acting beyond a straight line. Transversely across this framework canvas is securely stretched, excepting for about the middle fourth; here one or more wide strips are fastened by hooks, and are readily removable. Strong cords are fastened to the framework of the lift by means of hooks and rings, four in number, and are attached to a ring through which the hook at the end of a lever six or seven feet long is passed. This lever has a second hook, which is attached to the end of a chain suspended from the ceiling, and at its extreme end is a chain which can be fixed to a staple or some secure hold whilst the patient is being attended to after having been lifted from the bed. This lift, which can be easily and cheaply made, has been tried by Dr. Batsford at the Marine Hospital of St. John's, and would be very useful in cases where the medical man was short-handed and the patient required much nursing.

PECK'S AMBULANCE.

THIS, which would probably be more correctly termed a stretcher, appears to be well adapted for the purpose of removing cases of severe injury, especially accidents which occur in mines or pits. It possesses the advantages of portability, lightness, and strength, combined with moderate price. It may be used as a hand stretcher, or borne upon the shoulders of two men, and may also be slung in a carriage or cart by means of straps and spiral springs in such a manner as to obviate jolting. We consider it to be a good workable means of transport for the sick or injured.

THE CONTAGIOUS DISEASES ACTS.

THE Select Committee of the House of Commons reported favourably, as we have seen, of the Contagious Diseases Acts. They expressed an opinion that by their means venereal diseases had been diminished, and that the efficiency of the army had been increased. They declined to recommend their repeal, and they recommended the maintenance of the periodical examinations of prostitutes. In spite of this, however, these latter were discontinued shortly after the passing of Mr. Stansfeld's resolution on April 21st, 1883. It will therefore be both interesting and important to ascertain, so far as we can, whether any, and if so what, increase of disease has occurred among the soldiers in the various localities formerly protected by these Acts in which these periodical examinations were regularly enforced, which are still for convenience termed the protected stations; for although the Acts are in abeyance in these localities, they are not repealed; this cannot be effected without another vote of the House of Commons. Three Parliamentary papers, dated respectively March 7th, 1884, May 22nd, 1885, and August 6th, 1885, enable us to give some of the effects of the abolition of these periodical examinations. It will be remembered that the Acts were fairly in operation at all the fourteen stations from the commencement of 1870, but the promulgation of the order stopping the pay of men in hospital for primary venereal affections in 1873 led to considerable concealment of disease, and rendered the returns untrustworthy for the time. This order was cancelled late in 1879, and its repressive influence on the admissions removed. Early in 1883 (as we have seen) compulsory examinations of women were suspended, and their admission to hospital became voluntary on their part. There were thus two periods of three years each—1870–72 and 1880–82—in which the Acts were fairly in operation without either influence interfering with the results. The millesimal ratio of admissions for primary venereal sores, secondary syphilis, and gonorrhœa, at the fourteen stations under the Acts, at the fourteen never

Digitized by Google

under them, and at all the stations never under the Acts, for these two periods, with their percentage of increase or decrease, are given in the following tables:—

Stations.	Period.	Primary venereal sores.	Secondary syphilis.	Gonorrhœa.
Fourteen protected stations ...	1870–72	53·1	20·3	106·7
Do. do. do. ...	1880–82	75·6	26·6	98·9
Increase or decrease %	—	+42	+31	−7
Fourteen unprotected stations	1870–72	109·8	31·7	103·4
Do. do. do.	1880–82	175·9	38·7	128·2
Increase or decrease %	—	+60	+22	+24
All unprotected stations	1870–72	87·8	27·7	98·3
Do. do. do.	1880–82	123·0	32·5	110·5
Increase or decrease %	—	+40	+17	+12

These facts show that primary sores and secondary syphilis were much more frequent in all the groups in 1880–82 than in 1870–72; the increase at the protected stations was 42 per cent. for the primary sores, and 31 per cent. for the secondary form of the disease, as against 60 per cent. and 22 per cent. for the fourteen unprotected stations; or, if all the unprotected stations be included, the increase for primary sores was 40 per cent., and for secondary disease 17; but it must be observed that at both the lower ratios of 1870-72 were much in excess of the higher at the fourteen protected stations in 1880-82. As regards gonorrhœa, there was a decrease of 7 per cent. in 1880-82 at the fourteen protected stations, while in the other groups there was an increase of 20 and 12 per cent. in the same period. It is obvious from these details that the operation of the Acts limited the prevalence of venereal affections in a very marked manner, as compared with their frequency in other parts of the country where they were not enforced.

In THE LANCET for October 31st it was shown how the admissions of women into the certified hospitals began to fall off immediately after the compulsory examinations ceased in consequence of the vote in the House of Commons. The number now admitted is less than half that of former years, but this does not convey an adequate idea of the evil done. The women are admitted now on their own voluntary application, and the consequence is, as it has always been, that they do not apply in the early stage of disease, but later on, when from physical suffering they can no longer continue their calling. This circumstance explains the enormous amount of disease which is spread by these women when their diseases give them little or no suffering, while it also shows how much of this can be prevented by compulsory examinations.

We have seen how the Acts prevented disease among the troops stationed in those districts where they were enforced prior to 1883. Let us now see what effect the suspension of compulsory examinations had upon the men in the years 1883 and 1884. The admissions for primary venereal sores, secondary syphilis, and gonorrhœa among the troops in these years in the respective groups of stations already mentioned were per 1000 of strength as follows:—

Stations.	Period.	Primary venereal sores.	Secondary syphilis.	Gonorrhœa.
Fourteen protected stations ...	1883	109·5	25·2	99·4
Do. do. do. ...	1884	138·3	25·6	100·6
Fourteen unprotected stations ...	1883	188·3	44·3	133·7
Do. do. do. ...	1884	159·9	49·1	136·6
All unprotected stations	1883	116·5	28·5	105·0
Do. do. do.	1884	125·2	30·2	105·4

So that at the fourteen protected stations in 1883, when the operation of the Acts had been suspended for eight months, the admissions for primary venereal sores rose 45 per cent. above their average for 1880–82; and in 1884 there was a further rise of 38 per cent., when the ratio was 138·3, which was almost as great as it was at these stations in 1860 and 1861, when it was at its highest for the last twenty-five years. There was no corresponding increase elsewhere at the fourteen unprotected stations; the admissions for primary venereal sores in 1883 were only 7 per cent. higher than the average of 1880–82, and in 1884 they diminished sensibly; and if all the unprotected stations be compared, the ratio of 1883 shows a reduction of 5 per cent. on the average of 1880–82, though it regained this in 1884. Secondary syphilis presented little change in the last two years from what has been met with from 1880-82 at the fourteen protected stations, but in the fourteen unprotected there was a marked increase in 1883, which went on in 1884. When all the unprotected stations are taken together, however, the fluctuation is considerably less. Gonorrhœa has altered very little in the respective groups, but has remained most frequent at the fourteen unprotected stations.

In an early part of their voluminous report the Select Committee stated: "The extent of the subject induced your committee to exclude from their hygienic inquiry any special investigation into the effects of the Acts on the navy, and to direct their attention principally to the army, which affords adequate basis for observation and inference." We have already seen that the Royal Commission of 1870 reported favourably of the Acts in reducing syphilis in the navy, though there was an increase of gonorrhœa probably more apparent than real. In 1877 a Parliamentary paper was published giving a return showing the ratio of venereal disease in the crews of ships stationed at five home ports under the Acts, and at five home ports not under the Acts, from 1860 to 1875. The ports under the Acts are Dartmouth, Plymouth, Portsmouth, Queenstown, and Southampton. The ports not under the Acts are Greenock, Hull, Kingstown, Leith, and Liverpool. The result as regards the diminution of syphilis corresponds very closely to that obtained in the army. Thus in the years 1860-63, before any Acts were passed, the average annual ratio of syphilis was 75·02 per 1000 at the five ports since placed under the Acts, and 70·05 per 1000 at the five ports not placed under the Acts. In the years 1870-75, with the Acts in full operation, the average annual ratio was 43·52 per 1000 at the protected and 96·37 per 1000 at the unprotected stations; so that, latterly, the amount of disease at the former has been considerably less than half that recorded at the latter. The ratio fell 31·45 per 1000 at the one, but rose 26·32 per 1000 at the other. The cause of this rise at the unprotected stations, whatever it may have been, was probably also in operation at the others, and would have shown itself in them had it not been kept in check by the influence of the Acts, which should be credited, therefore, with the prevention of the rise as well as with the positive diminution. The difference, therefore, comparing the two sets of stations before and after the Acts, amounts to 57·77 per 1000 in favour of the protected stations.

As regards gonorrhœa the result is not so satisfactory, for there has been a very considerable rise in recent years. Thus, the ratio of gonorrhœa, which at the ports now protected was only 26·51 per 1000 in the years 1860–63 before the Acts, was as high as 63·08 in the years 1871–75, and at the unprotected ports it rose from 29·34 in the former to 52·36 in the latter. This increase of gonorrhœa is explained by the Director-General, Sir Alexander Armstrong, by the fact that, previous to the passing of the Acts, it was not the custom to place cases of gonorrhœa, unless severe ones, on the sick list; thus the majority of cases were not recorded. Since the Acts the attention of medical officers has been more closely directed to these diseases, and a large number of cases have been brought under notice which would otherwise not have been seen. The apparent increase which, it will be observed, has taken place at all the stations, whether under the Acts or not, may be attributed to the greater number of cases recorded, rather than to any real increase of disease.

Returning to the recently published Parliamentary papers already referred to, the naval returns do not specify the forms of venereal affection, but give all under one heading for successive half-years. The ratio per 1000 of the average force at Portsmouth and Plymouth of those admitted into Haslar and Plymouth Hospitals for "venereal diseases" were for the half year ending

	Haslar.	Plymouth.
June 30th, 1882	192·4	125·0
December 31st, 1882	191·7	104·1
June 30th, 1883	235·5	149·9
December 31st, 1883	283·7	230·7
June 30th, 1884	322·0	163·3
December 31st, 1884	312·7	156·1

Here, as in the case of the troops at the protected stations, the increase of the admissions after the suspension of the compulsory examination of the women (May, 1883) is very marked.

It has been therefore conclusively shown that the Acts were instrumental in preventing disease, and also that the abolition of their most important feature—the compulsory medical examination of prostitutes—has resulted in the reduction of women admitted into the certified hospitals, and in the increase of disease among the troops and among naval seamen.

THE LANCET.

LONDON: SATURDAY, JANUARY 2, 1886.

Anno exeunte a sober-minded retrospect becomes classes or bodies of men not less than individuals. There is always much to sadden in looking back; if it be only to think of the opportunities lost or inadequately utilised, or to compare performances with promises, the work actually done with that we intended to accomplish. *Anno ineunte* it is not less wise to think and speak soberly, but there is withal sound policy in taking a fairly rosy view of life and its prospects, if it only be to enable the mind to call into action its utmost energies for the initiation of good enterprise. We wish we could say that the outlook in medical science, and politics were even reasonably hopeful. It is far from our wish to pose as cynics or pessimists. We are, above all things, anxious to cherish a spirit of hopefulness. Nevertheless, it must be confessed, in all honesty, that the outlook *anno ineunte* is not of a nature to inspire cheerfulness.

In respect to medical politics—always distinguished from the politics of medical men—there is no good hope, or reasonable ground to anticipate, that the year upon which we are entering will differ widely from those which have immediately preceded it. Unless some great change should come over the spirit of the country and the Legislature the attention of public men will be so engrossed with matters of state policy at home and abroad, that very little, if any, time and thought can be spared for those concerns of the art and profession of healing and health-preservation which, while they really constitute the *conditions* of national prosperity, are readily crowded out of sight and forgotten when more clamorous business demands the lead. It is useless to cheat ourselves with the anticipation that the present or any other Parliament charged with such seemingly weighty matters as the pacification of Ireland, the reorganisation of Egypt, and the establishment of peaceful relations with the Powers of Europe and the world in general, to say nothing of such near future questions as that of the disestablishment of the Church, will have time or be in a mood to busy itself with the intricate questions of medical reform. If it should happen that these subjects are brought under the notice of Parliament, it will be at odd moments and, so to say, in the cuttings and parings of time. Clearly recognising this fact, we ought at once to perceive the immense practical importance of settling all disputes and adjusting differences *among ourselves*, so that any proposals that are made to the Legislature shall take the form of carefully drafted agreements, asking only the seal of authority to make them binding. It is useless, and would be fatuous, so far as any intelligible policy except that of delay is concerned, to go to the Government or to the Houses of Parliament with measures still in dispute. There cannot possibly be time for debate. If we are to get anything, it must be in direct reply to a special request. This applies to all questions of medical reform, whether general or special. It is simply puerile to expect the discussion of any measure in Parliament. The utmost that can be accomplished is the passing of some Bill agreed upon between ourselves, and so perfected that nothing remains to be done for us by the Legislature. If medical reformers of abuses will take this for granted, something may possibly be accomplished by their endeavours, but failing the perception of this fact there can be no progress.

For example, if London is to be placed on the same footing with other large cities in respect to the facilities afforded to students for obtaining degrees in medicine, there must be a final agreement as to the bases of any change which may be legally necessary before the question at issue is raised in Parliament. It will be worse than useless to send up vague prayers to the framers and makers of public law, because these gentlemen will be far too busy to hear us and answer our petitions. It is beyond question a scandal that residents in the metropolis should be compelled to go to the provinces or even into other divisions of the United Kingdom, for qualifications which ought to be obtainable at the fountain-head of authority. The admittedly grand *rôle* of the so-called University of London as an examining board is all too grand for the majority of students and practitioners. The degrees it confers are unquestionably proofs of learning on the part of those who receive them; but the efforts to obtain these high honours are out of all proportion to the exigencies of every-day life and practice. Both as regards the time they take and the work required, the game is not worth the candle to the many, and even to some who, perhaps, *could* gather the golden fruit if it seemed likely to repay the trouble of climbing so high for it. It is easy to understand that the medical graduates of the London University—to whom all honour—should be unwilling that the distinction which they have expended much time and thought to win should be placed within reach of the less ardent. This is not only perfectly natural, but right and just. Men with any self-respect who have not now that degree, which is practically an "honours" degree, would, we must believe, be averse from taking it if the conditions of its attainment were lowered. There is therefore obviously nothing left, save to meet the urgent need of a degree within reach of the average student in London by creating a more popular, and in a sense more genuine, university in the metropolis; and it seems clear to us that the only way of accomplishing this purpose is to bring about an affiliation of the existing schools in London, with a central body constituting a Senatus, thus creating out of the existing excellent materials a metropolitan university. There ought not, so far as we can see, to be any insuperable difficulty in carrying out this scheme. As far as a medical faculty is concerned, individual schools of medicine could be effectually represented by the conjoint Colleges of Physicians and Surgeons.

The prospects of medical reform in Parliament are *nil*; but medical reform may and will be attainable, even in the busy year before us, if only there be *substantial* and *detailed* Bills before the Legislature, the opposition to which has been previously threshed out and broken down, by the parties interested among themselves. If we will learn from the past, we shall succeed. Medical reform would have been easily accomplished two or three years

Digitized by Google

ago, but for the opposition offered by unsatisfied parties when measures came before Parliament. It is perfectly useless expecting to pass any Medical Bill for some years to come, unless opposition is averted. If medical reformers will lay this to heart and arrange accordingly, disappointments and unavailing regrets may be avoided.

THE moral success was complete of the meeting of Fellows and Members of the Royal College of Surgeons of England, held on the 17th ultimo, whatever may be its immediate effect upon the Council. A report of the meeting was published in our last issue, though the statement of the Council which was then formally presented had already appeared in our issue of Nov. 28th as a part of the report of an extraordinary meeting of the Council which was held on Nov. 24th. So far as it is possible to discover any meaning in the jumble of contradictions, inconsistencies, and sophistries of which the "statement" of the Council is composed, it would perhaps, on the whole, be more correct to say that the reiterated demand of the Fellows and Members for a larger share of the management of the College is evaded rather than refused. It was therefore merciful and pitiful to give the Council one more chance of redeeming its reputation and of saving its dignity by abandoning a position never secure, but now altogether untenable. Mr. HOLMES, as the spokesman of the Association of Fellows, moved the following resolution:—"That the answer of the Council is not satisfactory, and that the Council be respectfully requested to reconsider the subjects (1) of the representation of Members of the Royal College of Surgeons, and (2) of submitting for approval any alterations proposed to be made in the constitution, or in the relations of the College, or in any of its bye-laws, to a meeting of Fellows and Members." This was seconded by Mr. GAMGEE, as the mouthpiece of the Association of Members, and after a long, intelligent, and earnest discussion, was carried by an overwhelming majority. It is indeed both noteworthy and significant that, while several persons, including both Fellows and Members, spoke cordially in favour of the resolution, only two persons could be found, in a large and crowded meeting, to give utterance to the semblance of a contrary opinion, and neither of these ventured to move an amendment. Of these two speakers, one seemed to base his opposition upon an insurmountable dislike to changes of any and every kind; the other, on an apparent belief that, as the rights of Fellows and Members were defined by the Charters of the College, nothing could be done to alter them. This assumption implies ignorance or forgetfulness of the fact that the ostensible motive of the present agitation was the proposal of the Council to obtain certain alterations in the Charters. It was because the proposals of the Council did not go far enough that the resolutions were proposed and carried at the meeting of March, 1884. The history of the College furnishes several disproofs of the assumed finality and inalterability of a Charter. For instance, the notorious Charter of the year 1843 did materially alter and disturb the constitution of the College as founded by the Charter of the year 1800, and did gravely modify the rights, status, and relations of all Members of the College. If the Charter of the year 1843 could create a new order of Members to be called Fellows, and if it could confer upon these Fellows certain exclusive rights and privileges, it does not require much perspicacity to conceive that a Charter may be granted in, say, the year 1886, which will, among other things, provide for adequate representation of the Members of the College in the Council. What the precise nature and extent of the representation should be may still have to be definitively settled; though it is satisfactory to learn that the Association of Members has practically, and in the main, accepted the principle laid down at the general meeting of the Association of Fellows held last May—namely: "That it would conduce to the welfare of the Royal College of Surgeons, and would tend to promote the interests of medical polity and education, if Members of the College were empowered to take part in the election of members of the Council, provided, first, that no Member shall be eligible to vote until he have been such Member for a period of at least ten years; and secondly, that the number of members of the Council elected by the Members of the College shall not exceed one-third of the whole Council." (See THE LANCET, May 23rd, 1885, p. 963.)

Mr. RIVINGTON, in his sensible and appropriate observations on the resolution proposed by Mr. HOLMES at the general meeting held in the College last month, suggested that the Council should take steps to ascertain the individual opinions of the Fellows and Members on the points at issue. This is a practical and practicable way of proceeding. If the Council is really actuated by the lofty and disinterested sentiments it so persistently professes, let it issue the resolution of the Association of the Fellows and ask each Fellow and Member to signify his approval or dissent by the word "Yes" or "No."

THE charitable world has been startled by the proposal of "A Middlesex J.P." that every subscriber to a hospital should contribute on the condition that 25 per cent. of his subscription shall be given to the payment of current expenses, and 75 per cent. invested—that is, that a quarter shall go for the present wants of the hospital, and three-quarters for the future. We find it difficult to speak with proper patience on such a suggestion, which has met with telling replies from Mr. HENRY C. BURDETT and from Mr. F. C. CARR COMM, chairman of the House Committee of the London Hospital. The principle advocated by "A Middlesex J.P." is the very contrary of that generally approved by the intelligent supporters of hospitals, who rightly argue that the main duty of every generation of subscribers is to make generous provision for the sick poor of its own day, and leave to the benevolent of a future day the duty and the pleasure of providing for the sick of its own period. No doubt it is reasonable in the administrators of a hospital, large or small, to have a little reserve against a rainy day—for "some days must be dark and dreary"—like those we have at present. But that it is the duty of the present subscribers of hospitals to lay by 75 per cent. of their contributions for the benefit of future patients or a future generation is one of the most curiously wrong notions which we remember to have met with. The case would be different if we had met the misery which exists with adequate generosity—if we had subscribed enough "and to spare." But this is notoriously not the case; many

Digitized by Google

a poor man, woman, and child are suffering in straitened homes for want of a bed in a hospital, which the slightest curtailment of our luxuries would suffice to supply. Criticism has taken in many minds the place of charity. A keen eye for abuse has taken the place in them of a keen eye for suffering, and any charge against hospitals is entertained: "they are sectarian," "they are abused," "they are extravagant," "unfit persons gain admittance," and half a dozen other things are said of them, which damp enthusiasm, and serve as an easy excuse for not sending the subscription which every benevolent man feels disposed in his best moments to send, and which he would double if he could actually see the great care and skill with which the suffering are treated in any of our hospitals. We are not denying the occasional abuse of hospitals. We see by the *Newcastle Daily Leader* that Mr. JEAFFRESON, of Newcastle-on-Tyne, has been giving instances from his own experience. There is something in the retort of our contemporary that there is sometimes a want of accommodation in hospital surgeons to humbler patients in the matter of fees. It is also true that it is impossible to judge every case by a mere wage test or a rent test; and, further, it is true that many people avail themselves of hospitals for a big or occasional misfortune who ordinarily pay their medical man pretty well, and more than they would pay in any ordinary provident arrangement. But we do not doubt the existence of a considerable amount of abuse, though it has apparently been exaggerated. The abuse ought to be eliminated, but it is impossible to deny that our existing hospitals are inadequate to the charitable and kindly treatment of the really poor; and if Christianity itself is not to be discredited, if its favourite boast is not to be disproved, we shall have to exhibit far more generosity in hospital subscriptions and donations, and far less carping criticism. Let any humane man think of what the closing of wards of hospitals means in a community like London, and he will see the force of Mr. BURDETT'S and Mr. COMBE'S arguments in favour of more support for them. And the benevolent will not do badly if they consider that hospital the best whose expenses of administration are least, and which expends its money, not in investments, which, indeed, are now very attenuated in most London hospitals, but in receiving and relieving urgent cases of pain and disease.

A RECENT trial before the Lord Chief Justice, memorable alike for the forensic talent with which it was conducted and the weighty medical testimony with which it was supported, furnishes matter for serious contemplation of the physiological and pathological features of two complex functional disorders—diabetes and disturbed cardiac dynamism. It was admitted by the defendant company that an accident had occurred; but they denied, firstly, that the immediate injuries were as severe as alleged by the plaintiff, and, secondly, that neither the weakness and irregularity of the heart nor the glycosuria was the result of their negligence. Now, there is both experimental and ordinary pathological evidence that diabetes may be induced by injury to the cerebro-spinal system, and that part of it in particular which is known as the floor of the fourth ventricle. In fact, CLAUDE BERNARD demonstrated, and the observation can easily be verified, that puncture of the medulla oblongata at a certain spot—the so-called diabetic centre—is followed by the appearance of sugar in the urine. If the animal be left at rest, the glycosuria disappears in a few days, and, other injuries apart, it regains equilibrium of the glycogenic function. So, too in the human subject, it is not rare to find the urine of persons who have recently met with severe injuries to the skull to contain a trace—and it may be more—of glucose. With appropriate treatment, however, this chemical evidence of disordered innervation, vascular and special, vanishes in the great majority of cases, although it is certain that now and then, instead of being transient, it remains permanent. We are acquainted with a case of a man who was the subject of a very severe injury to the head, which produced a lasting crossed paralysis, palsy of the facial nerve, and hemiplegia on opposite sides. Twenty-seven years after the accident his urine was found to be loaded with sugar, and at the post-mortem examination a calcareous nodule, the size of a pea, was found in the medulla oblongata, and around it a tract of sclerosed nerve tissue. We imagine there can be little doubt that the lesion in question was the cause of the diabetes; to say the least, such an inference would have been considered by most medical men a fair interpretation of the facts, and one which a court of appeal would not be ready to set aside as "against the weight of evidence." We cannot subscribe to an assertion made at the trial recently concluded—viz., that because insensibility did not, as alleged, ensue upon the injury, that therefore the latter could not have produced diabetes, for the puncture experiment before referred to negatives such a conclusion. It seems to us that it is impossible to say with certainty that any one factor is the cause of diabetes in a given case. The decision must be grounded on the results of a balancing of probabilities, and this in the subject before us is necessarily a delicate procedure, for several theories may be found to fit the facts almost equally well. Diabetes in its minor degrees may certainly exist without the patient, or even his medical attendant, being cognisant of it. Nor need its existence cause any serious departure from accustomed health. The deaths from acetonæmia, which now and then occur without previous warning, support our contention.

Annotations.

"Ne quid nimis."

DECREASE OF ZYMOTIC DISEASES.

THE Supplement for the decennial period 1871–80, which has been recently issued by the Registrar-General, affords a remarkable confirmation of the value of the sanitary measures which now form so important an element of imperial and local administration in England and Wales. According to Dr. Ogle, the general rate of mortality has, when compared with that which prevailed during the ten years 1861–70, so far lessened as to exhibit a saving of 1144 lives annually to each 1,000,000 persons living; and the saving has to a large extent been effected by a decrease in the more preventable of the zymotic diseases. The scarlet fever mortality fell considerably, the annual deaths per 1,000,000 having diminished from 972 to 716; diphtheria exhibited a decrease from 185 per 1,000,000 to 121, but the

Digitized by Google

loose nomenclature used in connexion with this disease makes the returns under this heading unsatisfactory. The deaths from "fever," a term which includes typhus, enteric fever, and the ill-defined forms which are placed under such headings as "simple continued fever," fell from an annual average of 885 per 1,000,000 to 484. Enteric fever is essentially our English fever; it is the disease of all others the mortality from which affords a test of efficient sanitary administration, and a fall of no less than 45 per cent. is a testimony to a vast amount of excellent work. The deaths from diarrhœa also fell from an annual rate of 1076 per 1,000,000 to 935; in other words, there was an annual gain of 141 lives for each 1,000,000 persons living. The diminution in measles and whooping-cough was much less marked, and these are diseases which are hardly subject to such sanitary control as can be exercised. One disease, however, forms an exception to this general decrease—namely, small-pox, the mortality from which rose from 163 per 1,000,000 to 236. This rise was largely due to the fact that the serious epidemic of 1871 and 1872 is included in the decennial period referred to; but it has been partly due to an increase in adult small-pox amongst persons who have not been revaccinated, a subject to which we referred at length in our recent comments on the last annual report of the medical officer of the Local Government Board. This increase too, occurring as it has done in the face of a general decrease in the zymotic diseases which are essentially preventable ones, shows how incorrect it is on the part of those who deny the value of vaccination to assert that the general diminution of small-pox since the Vaccination Acts came into operation has been the result of improved sanitary administration. Apart from the protection afforded by vaccination and revaccination, small-pox is as deadly a disease as it ever was.

THE HOMES OF THE WINDSOR POOR.

WE have seen with much satisfaction that the opinion that Windsor must make a determined effort to improve the homes of its poorest inhabitants is gaining strength. In a leading article *The Times* has well urged the need of the improvements for which we have pleaded; and the Rev. Arthur Robins has in a letter which was published in that journal on Christmas Day again shown that the only effectual remedy which can be applied is the complete demolition of the worst areas, and the erection on their sites of habitations suited to the health and moral requirements of the people. Sir Henry Ponsonby has, at the instigation of the Duke of Connaught, promised to bring to the notice of the Queen the fund which Mr. Robins proposes to create, on condition that "the plan should be fully matured in conjunction with the authorities of the borough"; and we now learn that the Mayor has promised to meet Mr. Robins and his friends immediately after Christmas in order that they may take counsel together. There is, then, every prospect that a substantial beginning will be made of the steps which are necessary for the completion of the scheme. The purchase of the sites and the existing buildings can only be undertaken by the goodwill of the present owners. Unfortunately, the worst houses are those which remunerate most largely their owners. The poor invariably pay a rental which is altogether out of proportion to the character of the accommodation which is afforded them and of the money value of the property. A recent decision of an arbitrator of the Local Government Board, appointed to assess the value of certain insanitary buildings in St. Pancras, allowed no premium for compulsory sale, and had full consideration for the condition of the property. Proceedings taken under Torrens' Act by the local authority would, therefore, enable all houses which could be demolished under this Act to be removed at a reasonable cost. We presume, however, that arrangements will, if possible, be made for the clearance of sites without recourse to this measure, and, under these circumstances, it is earnestly to be hoped that the owners will meet the would-be purchasers in a liberal spirit. There should be no difficulty in the way of raising a considerable sum of money for the purpose of doing honour to the Queen and of improving the condition of the Windsor poor at the same time.

HOSPITAL PROVISION FOR INFECTIOUS DISEASES IN SALFORD.

THE relations that subsist between the guardians of the poor and the Town Council of Salford, as the sanitary authority for that borough, with reference to the expense incurred for the hospital isolation of infectious diseases, are just now under discussion in the General Health Committee of the Council. At the request of this Committee the medical officer of health (Dr. Tatham) has prepared and issued a special report on the subject, which has far more than local interest. In the provision of efficient hospital accommodation for the isolation and treatment of infectious diseases, Salford has taken a prominent place among the large towns of England. The local sanitary authority, at its Wilton Hospital, possesses 100 beds, which, as Dr. Tatham remarks, "*under ordinary circumstances*, will probably be sufficient for the isolation of such infectious cases as are likely to require removal, *with the one exception of small-pox*, which cannot safely be treated in close proximity to our present fever hospital." This hospital accommodation is supplemented by an arrangement with the authorities of the Monsall Hospital to receive such cases of infectious disease, including small-pox, as the Health Committee are unable to accommodate in Salford. Wilton Hospital was established in 1876 for the "isolation of such patients *other than paupers*, as could not be treated at home without risk"; but within a year of the hospital being opened an arrangement was made between the guardians of the poor and the Salford Town Council, by which paupers were admitted to the hospital on payment of a guinea a week by the Poor-law authority; and during the period from 1876 to the end of 1882 more than 37 per cent. of the patients treated in the hospital were paid for as paupers. In fact, during that period most of the patients were admitted on the order of the relieving officers. In 1883, however, the compulsory notification of infectious diseases came into operation in the borough, and through this agency the "sanitary inspectors received information of infectious sickness as early as, if not earlier than, the relieving officer, and consequently the patients were, in many cases, removed and their homes disinfected before application could be made to the Poor-law authority for relief." Under these circumstances the proportion of patients paid for as paupers declined to 6 per cent. in the two years 1883-84, although the proportion of patients in a position to contribute to the expenses of the hospital showed no increase. A deputation from the Health Committee therefore waited upon the guardians, and made such representations on the facts above referred to, that the guardians agreed to grant an annual sum of £500 to the Health Committee as a "contribution towards the treatment and maintenance in hospital of poor persons suffering from infectious disease." This arrangement received the sanction of the Local Government Board, and has since been in operation. The point now under the consideration of the Health Committee of the Town Council is an application to the guardians for an increased subsidy. Bearing in mind the large expense incurred by the maintenance of the hospital, and the undoubtedly economical

Digitized by Google

bearing of its operation upon the expenditure of the guardians in respect of out-door relief, it may be earnestly hoped that, in the interest of public health, as well as of Poor-law expenditure, the guardians will take a large and liberal view of the question, and of the request for an increased grant in aid of the expenses connected with the Wilton Hospital.

THE GOVERNMENT OF LONDON.

THE Parliamentary and General Purposes Committee of the St. Pancras Vestry have presented a report, which the vestry have adopted, upon the scheme which the Corporation of the City devised for the better government of London, and which is based on the principle of the establishment of a series of municipalities throughout the metropolis. The report agrees with the corporation scheme so far as it recommends that there should be a central body for common or metropolitan purposes, but disagrees entirely with the idea of ten separate municipalities. The committee are of opinion that there should be local municipal boroughs, each of which should have a council, which should manage all its local affairs, and the duties and powers of such local councils should be clearly defined in the Act; and also that there should be one central authority either elected from such local councils or by the ratepayers direct, and if direct, that they should be elected at the same time as the local councils, and those having the highest number of votes should be members of the central as well as of the local councils. The central council should have conferred upon it duties now performed by the Metropolitan Asylums Board, the School Board, and the Metropolitan Board of Works, so that there should be only one authority for metropolitan purposes, instead of the numerous and often conflicting authorities as at present. The new London government, the Committee think, should also deal with all questions of Poor-law administration. We observe in these recommendations the thoughts of Mr. T. Eccleston Gibb, the vestry clerk for St. Pancras, who has recently been elected M.P. for the Eastern Division of that borough. Mr. Gibb's presence in the House will materially strengthen the hands of any party seriously undertaking the reform of London government, and it may be expected that any legislation in which he takes part will have full regard for the health requirements of the metropolis.

FURTHER RESEARCHES ON MALARIA.

IN the current number of the *Fortschritte der Medicin* there appears a translation from the Italian of some further researches on malaria by Professor Marchiafava and Dr. Celli. The chief results so far obtained are thus summed up:—1. In the blood of individuals suffering from malaria there may be found in the interior of the red blood-discs minute organisms, composed of homogeneous protoplasmic particles, which are endowed with lively amœboid movements, and can be distinctly stained. These organisms are only found in the blood in cases of malaria, and are termed plasmodes or hæmoplasmodes of malaria. 2. In the interior of these units reddish or black pigment may be detected; but it is not an essential constituent, being merely derived from the hæmoglobin of the red disc. According as this pigmentation does or does not take place we have or have not melanæmia. 3. The hæmoplasmodes may be transformed by a process of fission into a group of granules which do not possess amœboid movements. This fission may occur in the pigmented as well as in the non-pigmented plasmodes, and it is most probable that this is the ordinary mode of multiplication within the human organism. Infection may occur as the result of the intravenous injection of malarial blood, as is shown not only by clinical experience, but also by the fact that in the blood of the receiver the hæmoplasmodes may be discovered. The units further increase as infection progresses, and diminish, until they disappear, as infection ceases, whether naturally or under specific treatment. The authors, in determining some of the last points, made experiments on a man aged forty-three, who was suffering from paralysis agitans, but who had never had any malarial fever. The blood was taken from a malarial subject during his apyrexial period, and the febrile movement commenced in the receiver the same evening.

A HIDDEN DANGER.

THE risk of conveying parasitic disease by means of the brushes and combs used in hair-dressing is not an imaginary one. It is no doubt much reduced in the better-class establishments by careful attention to cleanliness of the implements used, but even in them accidents are liable to occur at times from forgetfulness or neglect. A rush of customers cannot always be controlled, and there may not be time in each case to provide against the transference of contagion, which, perhaps, may be exceptional, and, as a rule, unlooked for in the course of a given business. Such unusual circumstances have nevertheless to be considered and dealt with. Some will insist that a good supply of brushes in permanent use, with regular cleansing, is the only reliable guarantee for all emergencies. Against the grounds of this argument nothing can, of course, be said. If the plan is borne out in practice, no ill can come of it. At the same time further suggestions are both admissible and welcome. Among such it may be well to note a method—in favour of which all others have been discarded—by a Liverpool operator. This consists in supplying each customer with a separate and personal brush, which is, in ordinary phrase, "given in" with the hair-cutting. The plan appears to pay, and we may readily believe the assurance of its originator—that by its employment the fear of parasitic troubles is reduced to a minimum. A comb is not mentioned as being given along with the brush; but this, again, can be much more easily and rapidly disinfected as required, and practically, we suppose, may be left out of account. Certainly the novel arrangement with regard to brushing is a gain on the side of healthy practice.

SANITARY SURVEY OF ST. LOUIS.

THE present and past sanitary history of St. Louis forms the subject of a volume by a number of contributors, the whole being a reprint from the Transactions of the American Public Health Association. The topography, climate, and sanitary administration are first entered into, and then come chapters on the sewerage and water-supply, and it is interesting to note how marked an effect proper sewerage and drainage schemes have had in reducing the mortality in those portions of the town which have been fully dealt with; but the absence of sewers in some localities leads, in this comparatively small town, to a mortality which exceeds that of London. All this is, however, in course of remedy, and in such details as the through ventilation of house-drains efficiency is now insisted on. The paving of the streets and minor thoroughfares, and a description of the milk service next follow, together with a review of the local industries, and of the chief local factors in the causation of disease. In an appendix is a brief account of the visitations from cholera which St. Louis experienced in 1849, from 1850 to 1854, and in 1866, and it is further shown how the sanitary organisation of that year led to a control of this disease in 1867, and to a rapid disappearance of the epidemic when it appeared for the last time in 1874. The last paper reveals one of the greatest dangers to which St. Louis is subjected—namely, the fact that the population resort to a

Digitized by Google

large number of local wells for water. Many of these wells are known to be foul, but we read of one sunk in a portion of the town which is thickly covered with old buildings, and from which the water is taken which provides the main manufacturer of soda-water. On three sides of the establishment are sewers, and close by is a filthy alley. So, also, this very block is described as a cholera centre thirty years ago. The detailed account of the public water service of St. Louis shows that it is not above suspicion either as regards its source or the quantity available for the population, but remedial measures were in contemplation when the report was written, and it is to be hoped that by this time further action has been taken in respect of this and other sanitary measures which are shown to be called for. It would be well if every city and town could refer to such a document for information as to its sanitary advantages and defects.

POISON FOR TWOPENCE.

THE evidence given at an inquest held last week by Mr. Bedford, the coroner for Westminster, serves to illustrate very strikingly the ease with which large quantities of deadly poison may be purchased without inquiry or restriction of any kind. It was stated that the deceased, a man named Winter, employed in the Catalogue Department of the British Museum, had suffered from periodical attacks of nervous prostation for some considerable time, probably for nearly six years; that he was of an excitable disposition, and would frequently absent himself from home for days together. About 11 o'clock on the morning of the 18th inst. he was seen to drink something from a tumbler, and on being questioned by his niece admitted that it was oxalic acid. He was removed to the Westminster Hospital, and died ten minutes after admission. We are not told how much was taken, nor what antidotal treatment was resorted to, but Mr. Swain, the house-surgeon, is reported to have stated in evidence that *for twopence enough poison could be purchased to kill two people.* This is an assertion which cannot be allowed to pass without inquiry and investigation. That deadly poisons are sold in this reckless way is almost inconceivable. If the Poisons Act permits the sale of oxalic acid to any and every chance comer, the sooner its powers are strengthened the better for all concerned. It is generally admitted that of late the responsible authorities have been slow to exert their powers.

BURNED TO DEATH.

IT is not less humiliating than terrible to think that for the want of obvious measures of safety ladies of position and refinement should succumb to "accident" by burning from the simple fact of a dress taking fire from a fallen candle, or in some similar fashion. Mingled with the very deep sympathy we feel for the victims of the last calamity of this sort—that which has just occurred at Stoke, near Devonport—there must needs be a deep sense of the grievous mistake so strangely made by even the most enlightened and well-informed in omitting to have dresses of the "light material" worn at balls so prepared as to render them non-inflammable. The initial fault, of course, lies with the manufacturers, who ought of their own forethought—or, if they will not, should be compelled by Act of Parliament—so to prepare the fabrics of which ball dresses are made that they shall be free from the peril of fire. That there is no insuperable difficulty in this process we all know, and it is one which ought to be generally adopted. It is idle to prescribe carefulness in the act of dressing or while wearing clothes of these specially light materials. "Accidents will happen" is an adage which none can gainsay. Nor is it possible to pen one word, except of regret, for the fate of the victim, whose impulse, fatal as it proved, was to run to the aid of the first sufferer. It is no use now to argue that the wearer of a similarly inflammable dress ought to have kept away instead of seeking to lend assistance. What would the world have thought of the poor lady if she had done the right and prudent thing in the emergency? The victim of her own good but impolitic impulse must be mourned by all generous hearts with respect rather than censure. The presence of mind shown by the step-father—who, happily for one at least of the sufferers, was at hand—is also to be highly commended; but it is heart-rending to think that not only might death and suffering have been prevented, but that the accident would not have occurred, if only the precaution had been taken to render the materials of which their dresses were constructed non-inflammable, by the manufacturer in the first instance, and by the laundress afterwards.

ALCOHOL IN INFIRMARIES.

MR. THOMAS ROBINSON, the secretary of the Sunderland Infirmary, has published a correspondence between himself and Dr. Philipson, of Newcastle, on the Consumption of Alcohol in the Sunderland Infirmary. He points out that the average cost per bed in Sunderland is 3*s.* 11*d.*, and not 9*s.* as stated by Dr. Philipson, the amount spent on alcohol in the Infirmary of Newcastle being 28*s.* per bed. Dr. Philipson, in reply, attributes the difference to the large proportion of severe surgical cases in the Newcastle Infirmary compared with that of Sunderland, and suggests that the mortality of such cases is less in the Newcastle than in the Sunderland institution. Mr. Robinson retorts in numerous letters, and with various statements. The chief of these is to the effect that in regard to medical cases the number of cures in the Newcastle Infirmary has steadily fallen in ten years from 58·80 to 24·86, and the death-rate has risen from 8·47 in 1875 to 12·01 in 1884; whereas in Sunderland the decrease was only that represented by 51·78 per cent. in 1885, and 64·37 in 1876. The average death-rate of surgical cases (including accidents) in Newcastle for ten years was 5·58 per cent., in Sunderland 2·45 per cent. Of capital operations in Newcastle, the average death-rate was 4·0 per cent., in Sunderland 2·43 per cent. We must say that we regard such wholesale statistics with very little confidence. It is scarcely conceivable that the mortality of medical cases in both the Newcastle and Sunderland Infirmaries is greater than it was ten years ago, and the cures less. We think the medical use of alcohol a question of great scientific and moral importance, but it is not to be settled by vague letters of this kind.

"RELIGIOUS HALLUCINATION."

WHAT is known as *religious hallucination* is really either the special development of a general morbid state—in other words, ordinary insanity putting on a particular type probably determined by the environment,—or it is a variety of hysterical excitement. There is in the weak and unstable minds of women a natural tendency to ecstatic engrossment with the subject of religion. This is fully accounted for by the fact that religious beliefs are the only remaining forms of mental excitation about the unknown and mysterious. The belief in fairies and witches and ghosts of all kinds has already died out in the minds of educated folk. No note need be taken of the lingering trace of these old phantasies which we find in the spiritism of the few who still cleave to the love of mystery. When the feminine mind, or the masculine mind of feminine grade, is perturbed, it naturally busies itself with the affairs of some other world. There is nothing in the least degree remarkable from a physiological point of view in this notorious fact. Nor is there anything strange in this particular form

Digitized by Google

of excitement, and others like it, being found to spread from one individual to another—in short, becoming epidemic. Just as stringed instruments are attuned to each other when long played in concert, and sensitive flames respond to vibrations propelled through the atmosphere, brains of like or "sympathetic" physical structure and organic habit are mutually responsive. The special features of any local or social development of the perturbation called "religious hallucination," are doubtless determined by the type of the class affected, and this, as we know, is determined by the conditions of heredity, life, growth, and education. There is nothing whatever wonderful in these phenomena. They are simple facts in the light of physiological science, and can be fully and clearly understood in this light only. The remedy for such visitations is further enlightenment. The time is probably not far distant when disturbances and phantasies of this sort will be wholly and everywhere things of the past.

STATE MEDICAL MATTERS IN VENEZUELA.

THE Venezuelan journal *El Ensayo Medico* mentions several reforms which seem greatly needed in Caracas, the capital of the republic. So many urgent cases occur in the night amongst people who are either so poor or so ungrateful that they do not pay a doctor when they summon him, that it is of great importance for the Government to establish a night service for providing medical aid to those in need of it. Again, there is, it seems, but one "municipal medical officer," who has long distances to travel and plenty of work to do; so that very frequently when he is urgently needed he cannot be found. The editor of *El Ensayo* mentions that people often come to him imploring him to go and look at a corpse, so as to give them a death certificate to enable burial to take place. Sometimes the case is of an infectious nature, and it is of the utmost importance that it should not be retained in the house; but it is impossible for a single municipal medical officer to be always able to attend to such cases without delay—and this, of course, is dangerous to those still alive. It is to be hoped that the city will see its way to making some better arrangements, whereby this delay may be avoided. A horrible system, too, is in vogue of taking the bodies from hospitals and the houses of the poor to the cemetery in shells, which, instead of being buried, are brought back and used repeatedly. These shells can hardly fail to be in many instances vehicles of contagious disease of various kinds from the dead to the living. There is one other point worth mentioning, and that is that the habit of going to church, especially on feast days, to pray for relatives who are sick or dead of an infectious fever, leads to the churches being in many cases dangerous hotbeds of infection. The editor has frequently seen people who have just been nursing yellow fever patients—feeding them, emptying their dejections and black vomit—praying in church, surrounded by numbers of other citizens. Surely medical men might do something towards minimising this danger by explaining certain necessary hygienic precautions to the families of patients afflicted with infectious disorders.

AZOTURIA.

AN estimation of the amount of urea discharged in a given time has been long regarded as a scientific means of diagnosis, not only in renal disease, but in other disorders which disturb the normal exchange of material. Within the last two or three years M. Rommelaere has made certain statements which, if true, would certainly afford additional help in the differential diagnosis of gastric diseases. Azoturia is a convenient term to signify the normal discharge of nitrogen in the urine. It used to mean hyper-azoturia, and we now also speak of hypo-azoturia. But difficulties still exist in the way of nomenclature, for no one knows the normal discharge of nitrogen. It is asserted in text-books of physiology that 500 grains of urea are the normal amount discharged by an average healthy man in the twenty-four hours. But this seems to be an arbitrary standard. The objections that have been raised against Rommelaere's conclusions (*vide* THE LANCET, p. 604, vol. ii., 1884) are four in number:—1. The estimate of thirty-two grammes for the normal azoturia is too large; in France it is given as twenty-one grammes. 2. Azoturia is proportional to the kind of diet. 3. A patient who is not fed, or who vomits his food, has hypo-azoturia, no matter what his disease. 4. Cancers may be associated with hyper-azoturia. Rommelaere admits the force of the first two objections, though he thinks his own conclusions are not perceptibly altered thereby. Theoretically there are objections, but not practically. He adduces evidence to show that the degree of azoturia is not in direct relation with the quality and quantity of the food in acute diseases, nor even in chronic affections.

THE BLACKWATER VALLEY.

THE stream into which some of the sewage of Aldershot, and the numerous hamlets along the marshy valley between Aldershot and Swallowfield, ultimately finds its way is, as we have already pointed out, in a very insanitary condition. Diphtheria has become almost naturalised along the line of this stream, and sporadic cases of typhoid occur from time to time. The surrounding district above the level of the valley is, with a few exceptions, very healthy. The soil of the higher ground is sandy, and permits filtration to take place to the lower ground, making this an unhealthy morass. A scheme is in contemplation for cleansing the Blackwater stream and lowering its level, so as to enable the valley to be drained. There is at present some want of unanimity among the local sanitary authorities interested in this matter. But it is a subject of far more than local interest; for adjacent to this valley, and more or less affected by its condition, stand the military schools of the country, as well as the military camp at Aldershot.

DIGESTIBILITY OF CHEESE.

THE digestibility of cheese depends a good deal, according to Klenze, on its physical properties. All fat cheeses are dissolved or digested with great rapidity, because the molecules of casein are separated only by the fat, and so the solvent juice can attack a large surface of the cheese at one time. Whether the cheese be hard or soft does not appear to matter, and there is no connexion between the digestibility and the percentage of water present in the cheese. The degree of ripeness and the amount of fat have, however, considerable influence, for both these conditions render the cheese more friable, and so allow of intimate contact of the juice. Cheddar took the shortest time to digest (four hours), whilst unripe Swiss cheese required ten hours for solution.

MEDICAL AGENCY.

AN important action has been tried in the County Court, Newport, in which Mr. Tritton, librarian of King's College, sought to recover £30 of Messrs. Elkington and Baddeley for introducing to them a partner—Mr. Morgan. It was not denied that Mr. Tritton had introduced Mr. Morgan, but it was contended that he was not a commission agent, and was not appealed to as such; and the defendants, while quite ready to pay a gratuity, objected on principle to pay Mr. Tritton as if he were a regular agent. In the end the jury decided that the defendants employed the plaintiff to

Digitized by Google

introduce a partner, and secondly, that the plaintiff did introduce Mr. Morgan. But they left it an open question whether the plaintiff should be paid for his services; and on being asked by the judge to say what would be a reasonable sum for his services, said £15, and judgment was given for that amount, each side to pay its own costs. Mr. Tritton would have done better not to have assumed the office of a medical agent. It is clearly not desirable that the officials of our medical schools should practise the callings of medical agents.

THE METROPOLITAN PUBLIC GARDENS ASSOCIATION.

THIS Society, in a circular issued a few days ago, has shown good reason why the sum of £4000 which is asked for in aid of its work should not prove too much for public liberality. Since its establishment in 1882-3, the Association has been engaged in 233 undertakings connected with the formation of playgrounds, public gardens, resting-places in thoroughfares, and gymnasia. Of these, eighty-three have been successfully carried out, eighty-five have been unsuccessful, and sixty-eight are now in progress. The year 1885 has seen the formation of twelve new spaces for recreation. The cost incurred on this head has varied from £46 to £1030 in different cases. For the payment of these amounts the Association has, in several instances, been much aided by the generosity of individual subscribers; in others, the weight of expense has been borne by its own funds. Another point worth noting is, that most of the labour devoted to these works has been sought for among the ranks of the "unemployed" labouring class. Trees have been planted in two thoroughfares, and seats provided where necessary. Money has been advanced to six public gymnasia in sums ranging from £10 to £100. The Public Gardens Association is not sectarian or illiberal in its aims or its donations. A part of its funds has gone to strengthen the efforts of other bodies working on the same lines as itself. Nor do its benevolent exertions take effect on any specially favoured metropolitan area. Islington, Battersea, Bethnal-green, Mile-end, Holborn, Clerkenwell, Westminster, and many other quarters, can bear testimony to the enlightened zeal of its members. The opening up of Highgate Woods and the formation of a public park at Kilburn are partly due to its representations. Much more work of a like kind remains to be accomplished in and around the crowded parts of London. That perfect success is hardly possible will appear from the failures which have mingled with the past achievements of the Association; but after making every deduction we may rest assured that the total sanitary gain from these improvements will repay a considerable outlay upon them.

HYGIENE IN POLAND.

THE medical faculties and press of Poland are deservedly renowned, especially, of course, in countries such as Russia and Bohemia, where their language is read. There has not, we believe, hitherto existed any popular journal in Polish dealing with sanitary matters from a scientific point of view. This want is now being met by the publication of a new monthly journal entitled *Zdrowie* (Health), the first number of which contains several interesting and instructive articles, among which we may mention the following. "On the Bath and its proper use in the case of both New-born and other Children." The writer describes the action on the skin, explains the importance of cleanliness, and alludes to the danger of employing water at too high a temperature. He also speaks of the use of salt-water bathing in rickets, which he terms the English Disease, and of which he explains the etiology and symptoms, with general directions for dealing with rachitic children. In an article on Mortality in Galicia are exhaustive tables and two excellent maps, showing by colours at a glance that the south-eastern portions of that province are the most unhealthy. The district in which the highest mean death-rate for five years (1878-1882) is noted is Horodenka, where it was 50·8 per mille, the lowest (26·8) being presented by Grybow. There are also articles on the Milk-supply of Warsaw, and on School Desks; likewise one on Cheap Dinners for Elementary Schools, in which an account is given of the English penny dinners at Board schools. A similar plan was tried in Warsaw, and it was found that they could be supplied at about the same price. We may be allowed to express a hope that this excellent journal will not suffer the same fate at the hands of the Russian censorship as its St. Petersburg namesake, to the suppression of which we have already alluded.

TESTING FOR COLOUR-BLINDNESS.

CONSIDERABLE dissatisfaction is, and we think with reason, expressed by the men engaged on various lines of railway, at the mode in which the test experiments for colour-vision are conducted. It is stated that many of these trials, in which specimens of wool are used, are made by gas-light. But the large proportion of red and yellow rays in the light produced by the combustion of gas renders it extremely difficult to distinguish between shades of blue and green. Magenta, again, which is of a reddish colour by day-light, is of a deep violet tint by lamp- or gas-light. So far therefore as the testing is exercised on wool, day-light should invariably be used, but it is different in the case of light, whether from gas or oil, which is transmitted through coloured glass. Such light is that which is ordinarily employed for signalling, and no complaint could be made if the guards and drivers were required to recognise various shades of blue, green, and red afforded by the light of an oil-lamp or of a gas-jet transmitted through such medium.

THE TEMPERANCE ESSAY PRIZEMAN.

THE Council of the Medical Temperance Association, on breaking the seal of the envelope marked with the motto to which their 100 guinea prize was last week awarded, found that the successful essayist was Mr. H. A. W. Coryn. The prizeman is a student of Charing-cross Hospital, and is a son of Mr. W. J. Coryn, M.R.C.S., of Acre-lane, Brixton. Three other competitors received from the adjudicators honourable mention—namely, Mr. R. W. Boyce, of University College; Mr. A. E. Norburn, of Guy's Hospital; and Mr. Hastings Gilford, also of Guy's Hospital.

THE PROSECUTION OF HERBALISTS.

LAST week, at Croydon, a herbalist calling himself "Professor" Stephen Jarrett was summoned at the Police-court, at the instance of the Commissioners of the Inland Revenue, for selling certain medicines without paying duty on the same, contrary to the statute. Four informations were laid against him, each for a penalty of £10. It appeared in evidence that an officer of the Inland Revenue purchased at the defendant's shop a bottle of "neuralgic mixture" and a packet of worm powders. On a subsequent occasion a second bottle of neuralgic mixture was bought, and also a box of dandelion pills. It was contended that all pills held up and recommended in any way as specifics to relieve any disorder were amenable to the Act. The defendant, on the other hand, urged that as he did not profess to practise any particular art in compounding the neuralgic mixture, which consisted only of one simple thing diluted with water, he was not liable. The Mayor, after fully considering the evidence, and after hearing the arguments

Digitized by Google

adduced on either side, decided that there had been a distinct infringement of the Act, and fined the defendant £1 and 13s. costs on each summons—in all £6 12s. We must confess that we have little or no sympathy with the provisions of the Medicines Stamp Act, but this is clearly an exceptional case, and we are glad to find that its provisions have been enforced. The number of so-called herbalists is greatly on the increase all over the country, and it is satisfactory to learn that steps are being taken to check their powers of doing mischief.

COTTAGES FOR RURAL DISTRICTS.

MR. WILLIAM MENZIES is the author of a book (published by Welham Clarke, Windsor) which contains a number of plans of cottages for the working classes, foremen, bailiffs, and head gardeners, with the necessary specifications. The work has been carefully done, but is nevertheless, we think, capable of some modification and improvement. Thus, in the plan of a single cottage and of a double cottage, rooms are shown which possess no fireplace. The single cottage, which is suitable for a foreman, does not appear to be provided with either an earth-closet, a watercloset, or a coal-cellar; in that suitable for a bailiff or head gardener no coal-cellar is shown, and there is an absence of cupboard accommodation which would be required for a house of that size. The linen-closets shown in a plan of double cottages and of a row of four cottages should, we think, have a window in the external wall. A few other points may be noted. In the specifications the concrete foundations are required to be one foot in depth; it is, however, obvious that the depth must vary with the character of the subsoil. Again, there is no provision for the trapping of the sink waste-pipe. It is true that the pipe is required to discharge over a gully-trap on the outside of the house, but in course of use it must necessarily become foul, and, without a trap, perhaps somewhat offensive. Altogether, however, the cottages are well planned, and the book, which contains drawings of cottages of all kinds, will doubtless be found useful to those who are proposing to erect dwellings of this character.

MITRAL STENOSIS AND LEAD-POISONING.

THE influence of saturnine intoxication on the various tissues of the body is a subject that merits even further attention than it has yet received. Neurologists are acquainted with a variety of nervous diseases clearly the outcome of lead-poisoning; and Dr. Gowers has, we believe, asserted that no symptom of nervous disease may not be due to lead. Vascular lesions have long been known to be caused by the prolonged action of this metal; and now M. Duroziez suggests that a limited lesion of the heart—mitral stenosis—may in a certain number of cases be due to the same far-reaching cause. The suggestion arises from his having observed several cases of mitral obstruction in house-painters, compositors, and certain polishers.

LAMPS IN BEDROOMS.

DR. LEY, of Newton Abbott, Devon, attributes a recent case of death by suffocation to the fumes of a lamp burnt during the night in a small bedroom. This is a most perilous way of lighting an apartment of limited capacity, and where there are no means of ventilation the use of lamps ought to be wholly interdicted. The naked flame of a candle is naturally dreaded in any room so full of light fabrics as a bedroom. Gas renders the atmosphere impure and overheated. It is difficult to make a useful suggestion, but clearly a lamp is full of peril. After all, perhaps the candle, protected by a glass shade or chimney, is the least objectionable of common appliances.

PRINCESS CHRISTIAN.

IT is satisfactory to find that Her Royal Highness Princess Christian has sufficiently recovered from her protracted illness to move from her bed to the couch, though at present the improvement is not sufficient for change into another room. The prostration of the nervous system from which it is believed the Princess has mainly suffered is a malady very slow of repair, and frequently arises from causes which are difficult to eradicate. Cumberland Lodge, the permanent home of Prince and Princess Christian, is a somewhat gloomy abode for a patient to whom a change of scene and habits of life are among the most important means of relief. A Royal personage is somewhat unfavourably circumstanced for efficient medical and general treatment. A limited acquaintance and few really intimate friendships preclude the possibility of social change and relaxation such as are within the range of less distinguished persons. Moreover, a change from home, with all appurtenances of Royalty, is an expensive undertaking, and the country has not been too liberal to this branch of the Royal family.

PARENCHYMATOUS NEURITIS IN TYPHOID FEVER.

THAT parenchymatous neuritis should occur in typhoid fever ought not to be regarded as altogether remarkable. M.M. Pitres and Vaillard have found changes in peripheral nerves which must be ascribed to neuritis. They do not indicate the frequency of such inflammatory changes in cases of typhoid fever, but they remark that the neuritis may be slight and transitory, or profound and lasting, when the key may be given to the explanation of certain paralyses occurring after typhoid fever, and which have not unfrequently been ascribed to lesions of the central nervous system. It has recently been shown that nervous changes are very frequently present in severe cases of typhoid fever, and indeed in any continuous fevers that are of much severity; also that there is some kind of alteration in the electrical reactions of the muscles. It is possible that the symptoms observed ought to be attributed to the actual presence of a fugacious and slight parenchymatous neuritis.

THE ABERDEEN INFIRMARY.

THIS knotty question has been the subject of a long discussion in the quarterly court of governors, but without receiving any satisfactory solution. A motion by Dr. Struthers, proposing to remit back to the committee instructions to proceed with the consideration of the reconstruction of the present building or to get plans or sites for a new one, was lost, and one by Sheriff Wilson of a temporising character, committing the governors to nothing till the managers have decided on the exclusion of contagious diseases and the number of patients to be provided for, and requesting further reports from the Committee of Management was carried.

"CHRISTMAS DAY IN A MADHOUSE."

UNDER this heading our contemporary the *Globe* gives a piquant account of the visit of one of its "amateur" contributors to St. Luke's Hospital on Christmas Day. There is nothing remarkable in the sketch—which is pleasantly written—except it be the *naïveté* of the amateur's profession of awe at entering an asylum, we must premise for the first time, and of his surprise at not finding the place a pandemonium and its officials ruffians trusting to physical force for the enforcement of discipline. It seems that a certain section of the public have yet to learn that insanity is a *disease*, or rather a class of diseases; and that the symptoms vary with the case. The worst patients, and those who

Digitized by Google

are capable of doing the greatest mischief if left to themselves, are often the quietest, and to the unskilled observer commonly the most sane. The days have long passed in which a "madhouse" meant a menagerie of raging lunatics, with "keepers" armed with instruments of coercion, or even torture. Nowhere, in this country at least, will the "amateur" find anything to "shock his feelings," or of which *he* is likely to make indignant complaint.

CHOLERA INTELLIGENCE.

SOME two weeks ago cholera was reported to be present in the neighbourhood of Venice, and during the past eight days stokers on board the Austrian Lloyd steamships between Venice and Trieste have conveyed the disease to the latter port, where at least two cases have terminated fatally. Considerable precautionary measures are being taken by the Trieste authorities, and, subject to the approval of the Austrian Government, all intercourse with Venice, whether by land or sea, will be prohibited. The most important feature of these appearances of cholera in the northern Adriatic ports lies in the prospect of a recrudescence of the disease next summer. The outbreak on board the steamer *Dorunda*, which conveyed emigrants to South-Western Australia, has not yet finally ceased, but news from Brisbane is to the effect that it is rapidly disappearing.

COTTON-WOOL AS A SURGICAL DRESSING.

As President of the Academy of Medicine and one of the honorary surgeons to the Hôtel Dieu of Paris, M. Alphonse Guérin has lately published a volume of 400 pages on Cotton-wool Dressing and its application to Surgical Therapeutics ("Du Pansement Ouaté et de son Application à la Thérapeutique Chirurgicale." Baillière. 1885.). The historical interest and practical merit of the work are unequal. Its claim to priority cannot be conceded without injustice to Burggraeve and other authors; but Guérin is an enthusiastic advocate of elastic compression, immobility, and infrequent dressing. He employs a large quantity of cotton-wool and many bandages, and attributes great importance to filtering the air so as to deprive it of germs, in which he appears to be as great a believer as Pasteur himself.

UNILATERAL ŒDEMA.

A CASE is reported by Dr. Bassi in the *Rivista Inter. di Med. e Chir.*, in which an hysterical young woman presented the curious phenomenon of a unilateral œdema that appeared with each menstrual period. There was no other derangement of general health, although the patient is described as delicate. The œdema was absolutely limited to the right half of the body, but there was no alteration in the colour, the temperature, or the sensitiveness of the two sides, although less irritation was necessary to produce reddening of the skin on the right side. Concurrently with this temporary œdema there were signs of congestion of the lung on the same side, and the right ovary was painful. Complete anæsthesia of both cornea and of the fauces was observed.

THE CORONERSHIP OF NEWCASTLE-ON-TYNE.

WE regret to see that the just claims of the profession in Newcastle to the office of the coronership are likely to suffer at the approaching election by the fact of two medical men competing. Both are men of standing, and either will make a good coroner. But for both to go to the poll is to ensure the defeat of the profession. Let us hope that one will give way. As our Newcastle correspondent says, Alderman Newton's public claims are very strong, and it would be a gracious act in Mr. Hardcastle to withdraw.

MENINGO-ENCEPHALOCELE.

A REMARKABLY large meningo-encephalocele springing from the region of the anterior fontanelle, in a female child aged two months and a half, was shown before the Medical Society of the Mauritius by Dr. Laurent, a graduate of the University of London. The shape of the tumour was reniform, and it had somewhat the aspect of an elephantoid scrotum, and was pediculated. It was twice the size of the fœtal head. The tumour was removed with strict antiseptic precautions, but the infant collapsed. The mother of the child had been shocked, when she was in the second month of pregnancy, at the sight of an elephantoid scrotum exhibited to a crowd by a drunken man.

OVARIOTOMY IN CAGLIARI.

THE first ovariotomy in the capital of the island of Sardinia was performed on Sept. 2nd by Dr. Angelo Roth. The patient, aged twenty-three, single, had suffered for six years from a right ovarian cyst. This contained twenty-two litres of thin liquid, and was removed through an incision ten centimetres in length. The pedicle was tied in three portions and dropped into the cavity. No drainage-tube was used, but toilette of the peritoneum preceded the use of sutures. Under an antiseptic dressing cicatrisation was complete on the seventh day.

PRURITUS.

SOME cases of pruritus of the vulva and anus are of very obscure origin. Neither local mischief, intestinal, vaginal, hepatic, renal, neurotic, or other disorders can be made to account for them. M. Brown-Séquard believes that coffee may have something to do with the production of the condition in some cases, since he has seen relief follow the removal of coffee from the dietary in two instances.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of November, 1885, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained a larger proportion of organic matter than in any month during the last three years. This sudden change in the quality of the supply is due to the prolonged floods which have prevailed in the river. The water drawn from the Lea and distributed by the New River and East London Companies also exhibited a marked increase in organic matter, the proportion, however, being less than in any of the Thames waters. All the samples, with the exception of that of the Grand Junction Company, which was slightly turbid, were clear and bright on delivery. The number of micro-organisms found by the gelatine process in one cubic centimetre of the waters of the various companies was as follows:—Chelsea, 3; West Middlesex, 5; New River, 11; East London, 14; Lambeth, 26; Southwark, 32; Grand Junction, 40; River Lea (unfiltered), 954; River Thames (unfiltered), 1866.

THE death is announced of Dr. Albert H. Smith, of Philadelphia, which took place on Dec. 14th. Dr. Smith was in his fifty-first year. He was one of the founders of the Philadelphia Obstetrical Society, and contributed largely to the literature of midwifery and gynæcology.

THE Moscow popular medical journal, *Doktor*, will next year change its name to *Novosti Terapii* (Novelties in Therapeutics), and will deal with the progress of therapeutical science and with the literature of the subject.

Digitized by Google

THE Russian Red Cross Society is sending to Bulgaria and Servia two "sanitary corps," each of which consists of six military surgeons, six feldschers (hospital sergeants), and twelve Sisters of Mercy. These last belong to the George and Alexander sisterhoods, and most of them served in the Russo-Turkish campaign, and have therefore considerable practical experience.

THE Russian *Viedomosti* reports that the local administrative body of a division or county of the province of Kursk have dismissed two female doctors it had engaged, because the Provincial Medical Committee informed it that female practitioners were incompetent to take charge of a district, being only allowed to treat women and children.

THE first Lettsomian Lecture will be delivered at the Medical Society on Jan. 4th at 8.30 P.M. Mr. Jonathan Hutchinson will treat of the mutual relationship of different forms of primary venereal sore, the causes of phagedæna in primary sores, recurring chancres, and different forms of bubo.

A PRESENTATION of plate has been made to Dr. Protheroe Smith by the medical staff of the Hospital for Women, Soho-square, on his retirement as Physician and appointment as Consulting Physician to the hospital.

IN the *Gazzetta degli Ospitali* (Nov. 18th), Dr. Miliotti relates two cases of rapid cure of sciatica by congelation with ethylic ether.

DR. WEBER LIEL, Professor of Otology in Jena, has been obliged by ill health to resign his post.

DR. METZGER of Amsterdam has been to Rome to give the Pope the benefit of his advice.

Pharmacology and Therapeutics.

THE ELIMINATION OF BISMUTH.

M. HANS MEYER has poisoned mammals and birds by injecting under the skin or into a vein large quantities of the salts of bismuth. At the necropsy the large intestine and its surroundings were seen to be of an intense black colour; often there existed also large tracts of necrosis of the mucous membrane of the large intestine, whilst the stomach and small intestine preserved their normal appearances. Chemical analysis of the wall of the intestine and of the contents has demonstrated that the digestive tube all along serves as an excretory surface for bismuth, but that this elimination takes place much more actively at the surface of the large intestine, and that the metal is excreted in the form of a sulphide. By previously making the animals ingest preparations of sulphur, the elimination of bismuth was augmented in the stomach and small intestine, and the wall of the stomach became pigmented of a deep black colour. The author concludes from these facts that the presence of sulphuretted hydrogen favours the elimination of the bismuth by precipitating the metal from the capillary circulation of the intestine in the form of the insoluble sulphide, which plays the part of a foreign body. If this precipitation does not take place, the metal re-enters the circulation, and is eliminated largely by the kidneys. As the necrotic tracts and ulcerations are met with almost exclusively in those portions of the digestive tract where the pigmentation obtains its greatest intensity, the conclusion is naturally arrived at that the precipitation of the bismuth in the thickness of the intestinal mucous membrane has caused the necrosis and ulceration by the precipitate blocking the capillaries and vessels of the parts concerned. Further, if the animals are made to ingest simultaneously salts of bismuth and substances that disengage sulphuretted hydrogen, neither necrosis, ulceration, nor pigmentation of the intestine occurs, evidently because the bismuth and sulphuretted hydrogen in combining mutually neutralise each other. According to Hans Meyer, also, it is probable that in mercurial poisoning the inflammation and necrosis of the gastro-intestinal mucous membrane depend, in a similar manner, on putrid fermentations which disengage sulphuretted hydrogen. It is well known that the prevention of mercurial stomatitis by the use of dentifrices and antiseptic lotions is due to their property of preventing the processes on which the development of sulphuretted hydrogen is dependent.

TSUCHIAKABI.

This drug is the fruit capsule of an orchid indigenous in Japan, and used there for a long time past. The capsules possess an acid and bitter taste, and contain a substance which is largely soluble in water. By treatment with spirit, an extract can be obtained which has a sharp but not unpleasant taste. It is composed of a resin, acid and glucoside, to which is probably to be attributed its medicinal properties. The urinary bladder and passages are the parts of the body on which the medicament exerts its special action. The Japanese employ a watery extract of this drug, which would be administered in those cases for which cubebs and copaiba are prescribed, with the advantage of the absence of the disagreeable odour of the last-named drug.

CASCARILLA BARK.

An alkaloid almost identical with choline has been discovered in the bark of cascarilla by Professor Boehm. The bitter crystalline cascarillin may be converted into an amorphous resin that still retains the poisonous properties of the crystalline substance, which is a nerve poison. The essential oil of cascarilla is a third constituent of the bark, but it has no noteworthy physiological action.

CORROSIVE SUBLIMATE FOR HYDROCELE.

Sarrazin reports on five cases of hydrocele that he has treated by injection of a solution of corrosive sublimate of the strength of 1 in 1000. The advantages are the harmlessness of the solution, and the circumstance that suppuration is never excited, a simple form of adhesive inflammation being provoked. All the five cases were completely successful.

GEOLINE.

Geoline is very much like Vaseline in general appearance, and it is employed for much the same purposes. It is said never to turn rancid. We have examined a sample of this product of petroleum, and it appears to us to possess all the advantages that are claimed for it; under most favourable circumstances for decomposition we have found it to retain its purity.

THE INTERNATIONAL MEDICAL CONGRESS.

THE special announcement of this Congress has reached us. It is issued by the executive committee, who intimate that they have nearly completed the arrangements for the meeting, and anticipate the hearty co-operation of the profession everywhere in developing "this great scientific and humanitarian assembly."

The following letter has been addressed by Dr. Sayre to F. S. Dennis, M.D., Associate Secretary-General of the Congress:—

"285, Fifth Avenue, N.Y., Dec. 1st, 1885.

"DEAR DOCTOR,—I have just been informed that there is a current rumour that I have resigned from the International Congress, and that I have refused to have anything to do with the meeting. This statement is so absolutely untrue that I write you at once, and request you to correct the erroneous impression as far as possible. I resigned from the committee of arrangement on account of my health not permitting me to perform the arduous duties connected therewith; but I have gladly accepted the position of vice-president, and am delighted to know that there is every prospect of a most successful meeting.

"Very respectfully,

"LEWIS A. SAYRE."

The following is the list of officers nominated for election by the Congress:—President of the Congress, Austin Flint,

Digitized by Google

M.D., LL.D., New York. Vice-Presidents of the Congress: W. O. Baldwin, M.D., Montgomery, Alabama; Wm. Brodie, M.D., Detroit, Michigan; W. W. Dawson, M.D., Cincinnati, Ohio; E. M. Moore, M.D., Rochester, N.Y.; Tobias G. Richardson, M.D., New Orleans, Louisiana; Lewis A. Sayre, M.D., New York, N.Y.; J M. Toner, M.D., Washington, D.C.; the President of the American Medical Association; the Surgeon-General of the United States Army; the Surgeon-General of the United States Navy; the Supervising Surgeon-General of the United States Marine Hospital Service. Secretary-General of the Congress: Nathan S. Davis, M.D., LL.D., Chicago, Illinois. Associate Secretary-General: Frederic S. Dennis, M.D., New York, N.Y. Treasurer of the Congress: E. S. F. Arnold, M.D., New York. Chairman of the Finance Committee: Richard J. Dunglison, M.D., Philadelphia.

We are glad to note a decidedly different tone and spirit in several of the leading medical journals of the States in this matter, expressing a wish for the settlement of differences and a willingness on certain conditions for hearty co-operation. This does not surprise us. Our estimate of the good sense and feeling of our Transatlantic brethren has never permitted us to believe that such a catastrophe and discredit as the failure of the Congress on its removal to Europe could happen. There seems now every prospect that differences will be adjusted, and adjusted at home, by a little giving and taking on each side, of a controversy in which both sides have meant well.

WILLS OF MEDICAL MEN.

THE will and codicil of Stephen Monckton, M.D., late of Maidstone, Kent, who died on September 30th last, were proved on Nov. 21st by Mr. Robert Monckton, the brother, Mr. Joseph Arthur Burrell, and Mr. Stephen Launcelot Monckton, the son the executors, the value of the personal estate amounting to upwards of £29,000. The testator bequeaths £100 and all his furniture and effects to his wife, Mrs. Maria Monckton; the goodwill and benefit of the connexion of his practice as a medical practitioner, with all his books and professional appliances, to his son, Henry Holland Monckton; £1000 upon trust for his sister, Miss Maria Monckton, for life, and then for the lineal descendants of his father, Mr. Jonathan Monckton, as she shall appoint; and £50 to each of his executors. The residue of his real and personal estate is to be held upon trust to pay the income to his wife for life, and then for his son, Stephen Launcelot Monckton, absolutely. The provision made for his wife and children is in addition to that made for them by his marriage settlement, which he confirms.

The will and codicil of Mr. John Gay, F.R.C.S., formerly of No. 34, Finsbury-pavement, but late of No. 51, Belsize-park, Hampstead, who died on September 15th last, have been proved by Mrs. Elizabeth Gay, the widow, and Mr. John Gay, the son, two of the executors, the value of the personal estate amounting to over £23,000. The testator bequeaths his plate, jewellery, pictures, furniture, effects, and all his money at the Union Bank, to his wife; £1000 to his daughter, Florence Elizabeth Gay; and legacies to two servants. The residue of his real and personal estate he leaves upon trust for his wife for life or until she shall marry again, and then as to one-third for each of his three children, John, Arthur William, and Florence Elizabeth.

The will of David Chalmers, M.D., late of Liverpool, who died on August 21st last, at Lambeth-road, Southwark, was proved on the 25th ult. by Mr. Anthony Wigham Chisholm, the brother, and Mr. Thomas Chilton, the executors, the value of the personal estate amounting to over £18,000. The testator gives £200 to his wife, Mrs. Ellen Chalmers, and all his plate, pictures, books, furniture, and household effects, and £400 per annum to her for life. The residue of his real and personal estate, including the considerable real estate purchased by him in Colorado, he gives to his three children, Thomas Dodson, Harriet Weatherhead, and Harold, in equal shares.

The will of Francis Harris, M.D., late of No. 24, Cavendish-square, and of The Grange, Lamberhurst, Kent, who died on the 3rd September last, was proved on Nov. 10th by Mr. Charles Edward Harris and Mr. Charles Quincey Roberts, the nephew, the executors, the value of the personal estate exceeding £15,000. The testator bequeaths the cash at his bankers, his residence, No. 24, Cavendish-square, and all his jewellery, plate, pictures, furniture, effects, wines, horse, carriages, live and dead stock, to his wife, Mrs. Marianna Harris; £200 to each of his executors; and £4000 Government stock upon trust for his brother, Joseph Robert Harris, for life. His real estate at Lamberhurst, subject to a right given to his wife to use and occupy the mansion-house, The Grange, for life, he devises upon trust for his son Owen. The residue of his personal estate he leaves upon trust for all his children in equal shares.

The will of Mr. Augustus Law, Surgeon in the Peninsular and Oriental Company's service, late of No. 14, Woburn-place, who died on October 10th last, has been proved by Miss Sarah Matilda Law, the half-sister, and Mr. Stephen Hugh Grestock, the executors, the value of the personal estate amounting to over £4,000. The testator bequeaths £400 each to his step-mother, Mrs. Sarah Ann Law, and to his god-daughter, Florence Harriet Hogg; £500 to Mrs. Mary Annie Harriet Quayle; £300 to his niece, Mrs. Eliza Phillips; and a complimentary legacy to his executor, Mr. Grestock. All his real estate, if any, and the residue of the personalty, he gives to his said half-sister.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Abraham Altham, of Burnley, Lancashire, tea merchant, £500 towards erecting a children's ward at the Victoria Hospital, Burnley, and £500 to the endowment fund of the said hospital, if he has not given such sums in his lifetime.—Mr. William Augustus Guy, M.B., F.R.S., F.R.C.P., of No. 12, Gordon-street, Gordon-square, £250 each to King's College Hospital, and King's College Hospital Convalescent Institution; and on the death of his wife, or twenty-one years after his death, which shall first happen, one half of a moiety of the residue of his real and personal estate, which is left upon trust for accumulation in the meantime, to King's College Hospital Convalescent Institution.—Mr. William Hunt, J.P., formerly Mayor of Bath, late of No. 72, Pulteney-street, Bath, £25 to the Bath Royal United Hospital.—Mrs. Mary Blackden, of No. 6, Norfolk-crescent, Hyde Park, £300 to the Convalescent Institution, Walton-on-Thames; and £200 to St. Mary's Hospital, Paddington.—Mrs. Louisa Brooke Blake, formerly of Andersey, St. Mary Church-road, but late of Sunnylands, St. Mary Church, both in Torquay, £100 to the Torbay Infirmary and Dispensary.—Mr. Joseph Stevens, of the firm of Whiteley, Stevens, and Co., lace merchants and manufacturers, late of Stapleford and Nottingham, Nottinghamshire, and of Sandiacre, Derbyshire, £1000 to the Nottingham General Hospital; £500 to the Midlands Institution for the Blind, Nottingham, and £100 each to the Nottingham and Midlands Eye Infirmary, Nottingham, and the Nottingham Dispensary, Broad-street, Nottingham.—Mr. Henry Aste, of Castle-hill Lodge, Norwood, £200 to University College Hospital; £100 each to the North London Consumption Hospital and the Royal Hospital for Incurables, Putney; and £20 to the Margate Sea-bathing Infirmary.—the Right Hon. Katherine Anne Viscountess Cranley, of No. 2, Downe-terrace, Richmond, one moiety of £1000 consols to the Hospital for Consumption, Brompton.—Miss Maria Hebden, of No. 15, Compton-terrace, Islington, £100 each to the Holloway Dispensary, Islington, and the Society for Incurables, Clapham-rise.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Portsmouth Urban District.—The account which Dr. Sykes gives of Portsmouth is in several important respects one of considerable gravity. The past year is stated to have been a more favourable one, as regards enteric fever than any in the sanitary history of the borough. Yet 539 cases were notified, and 58 deaths occurred. And unfortunately the conditions ensuring the maintenance

Digitized by Google

of this disease remain. There has been a bye-law in force since 1870 which provides that every cesspool shall be made water-tight, properly covered in, and ventilated; and yet Dr. Sykes says he has failed to find one such properly constructed receptacle in the borough, and the consequence is that building which is going on in the undrained portions of the district is leading to a pollution of the soil which, at the very least, must last for many years to come. Diphtheria, too, has been very prevalent, 174 cases having come to the notice of the sanitary department. And this is not all. In this borough, which may at any time receive the infection of cholera from abroad, we read not only of soaking and ill-constructed cesspools and of undrained areas, but in parts of the town the old-fashioned and highly objectionable pit-privy exists, the hole being emptied at rare intervals only, and the fluid escaping at times under the foundations of the houses to which the structures belong. Last year, H.M.S. *Crocodile* arrived at Portsmouth having had cholera on board, but fortunately the disease was over long before she entered the port. The same good luck may not attend the next arrival, and the conditions we have described will, unless speedily removed, go far to aid in the spread of the infection. Fortunately a great scheme of sewerage is in contemplation. Portsmouth has a hospital for infectious diseases, but, to say nothing of a large prevalence of measles, there were 974 cases of the other infectious fevers notified to the authority, and yet only twenty-two cases were admitted for the purposes of isolation. Surely, something is very wrong here, either in the way of restrictions to admission, or else in the failure to remove some cause which deters people from allowing first cases of infectious disease to be properly isolated. The annual death-rate for 1884 was 19·2; the average for ten years having been 19·8.

Birkenhead Urban District.—This borough, with a population of 90,870, had in 1884 a birth-rate and death-rate of 38·06 and 19·46 per 1000 respectively, the latter comparing favourably with the large cities and towns of England. The zymotic rate was 2·2 per 1000, which is also by no means unsatisfactory. Small-pox was epidemic in Liverpool during a considerable portion of the year, and communication between the two places is all but continuous; the disease was again and again imported, and some ninety cases were removed to the isolation hospital, but the prevalence did not make any considerable headway. Of the vaccinated 3·4 per cent. died, the fatality amongst the unvaccinated being at the rate of 38·0 per cent. Under the system of compulsory notification in force, 1463 cases of infectious disease came under notice. Uncertified deaths are unfortunately on the increase in the borough, and, as a natural consequence, the public have no guarantee as to the proceedings which preceded death. A very large amount of valuable sanitary work is steadily in progress in the borough; but as regards overcrowding in common lodging-houses and night occupation of cellar-dwellings, Mr. Vacher very properly points out that, in the absence of a night inspector, his department cannot regard the supervision exercised as in any way complete. The isolation hospital did good service during the year; the compulsory notification system has not led to the secreting of cases, and so to the production of an apparently increased death-rate; and a considerable amount of disinfection of dwellings and of infected articles was carried out by competent officials. Under the Birkenhead Improvement Act of 1884, cowkeepers and others are required to furnish lists of customers in certain cases, and the authority are empowered, when notifying to a person to abate a nuisance, to prescribe the description of the acts or work required to be done or of the materials to be used. Provisions of this sort are of the utmost importance to efficient sanitary administration, and, provided they are surrounded by a reasonable amount of safeguard, they ought to, and probably will some day, be included in an Act which shall have universal application.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 4543 births and 3289 deaths were registered during the week ending Dec. 26th. The annual death-rate in these towns, which had been 20·3 and 23·0 per 1000 in the preceding two weeks, declined last week (owing in great measure to delay in registration due to the Christmas holidays) to 19·3. During the first twelve weeks of last quarter the death-rate in these towns averaged only 19·6 per 1000, and was 2·8 below the mean rate in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 13·6 in Brighton, 14·2 in Leicester, 15·1 in Hull, and 16·0 in Norwich. The rates in the other towns ranged upwards to 25·8 in Cardiff, 26·3 in Birkenhead, and 28·4 in Bolton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 352 and 419 in the previous two weeks, declined again to 395 last week; they included 126 from whooping-cough, 122 from measles, 55 from scarlet fever, 34 from diarrhœa, 30 from "fever" (principally enteric), 24 from diphtheria, and 4 from small-pox. No death from any of these zymotic diseases was recorded last week in Wolverhampton, whereas they caused the highest death-rates in Liverpool, Salford, and Bolton. The greatest mortality from whooping-cough occurred in Brighton and Bolton; from measles in Birmingham and Nottingham; from scarlet fever in Leicester, Sunderland, and Preston; and from "fever" in Salford. The 24 deaths from diphtheria in the twenty-eight towns included 14 in London, 2 in Liverpool, and 2 in Salford. Small-pox caused 3 deaths in Liverpool and 1 in Bristol; but no death from this cause was registered in London and its outer ring, or in any of the twenty-five other provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding seven weeks from 90 to 50, had further fallen to 48 on Saturday last; the small-pox cases admitted to these hospitals, which had been 6 and 13 in the previous two weeks, fell again to 9 last week. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding two weeks from 413 to 503, declined again last week to 384, and were 153 below the corrected average. The causes of 85, or 2·6 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton and Plymouth. The largest proportions of uncertified deaths were recorded in Oldham, Halifax, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·4, 23·7, and 24·1 per 1000 in the preceding three weeks, declined to 22·9 in the week ending Dec. 26th; this rate, however, exceeded by 3·6 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 10·6 in Leith and 18·7 in Dundee, to 24·9 in Glasgow, 26·6 in Perth, and 35·2 in Paisley. The 560 deaths in the eight towns showed a decline of 28 from the number in the previous week, and included 12 which were referred to whooping-cough, 9 to scarlet fever, 9 to diarrhœa, 6 to diphtheria, 4 to measles, 2 to "fever" (typhus, enteric, or simple), and 1 to small-pox; in all, 43 deaths resulted from these principal zymotic diseases, against 56 and 51 in the preceding two weeks. These 43 deaths were equal to an annual rate of 1·8 per 1000, which was 0·5 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 12 and 7 in the previous two weeks, rose again to 12 last week, and included 9 in Glasgow and 2 in Aberdeen. The deaths from scarlet fever, on the other hand, which had been 9 and 15 in the previous two weeks, declined again to 9, of which 5 occurred in Glasgow and 2 in Edinburgh. The 9 deaths attributed to diarrhœa showed a further decline from recent weekly numbers, and included 3 in Edinburgh, 2 in Greenock, and 2 in Perth. Both the deaths referred to "fever" and 5 of the 6 fatal cases of diphtheria were returned in Glasgow. The 4 deaths from measles included 2 in Paisley, and exceeded the numbers in recent weeks. The reported death from small-pox was a death referred to chicken-pox in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 178 and 175 in the preceding two weeks, further declined last week to 151, and were 27 below the number in the corresponding week of last year. The causes of 90, or more than 16 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·7, 31·0, and 34·4 per 1000 in the preceding three

Digitized by Google

weeks, declined to 22·8 in the week ending Dec. 26th. During the first twelve weeks of last quarter the death-rate in the city averaged 26·1 per 1000, the mean rate during the same period not exceeding 19·0 in both London and Edinburgh. The 154 deaths in Dublin last week showed a decline of no fewer than 79 from the high number returned in the previous week; and included 16 which were referred to the principal zymotic diseases, against 15, 23, and 28 in the preceding three weeks. Of these 16 deaths from zymotic diseases, 10 resulted from whooping-cough, 4 from "fever" (typhus, enteric, or simple), 2 from scarlet fever, and not one from small-pox, measles, diphtheria, or diarrhœa. These 16 deaths were equal to an annual rate of 2·4 per 1000, the rate from the same diseases last week being equal to 2·6 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had increased from 5 to 15 in the previous four weeks, declined again last week to 10. The deaths referred to "fever," which had been 7 in each of the previous two weeks, declined to 4 last week; and the 2 fatal cases of scarlet fever also showed a decline from the numbers in recent weeks. Five inquest cases and 5 deaths from violence were registered; and 39, or more than a quarter of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons showed a considerable decline from the numbers in the previous week. The causes of 25, or 16 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

DR. MACGILLIVRAY'S CASE OF REMOVAL OF AN ENFIELD BULLET (CRIMEAN) WHICH HAD LODGED FOR MORE THAN THIRTY YEARS IN THE INTERNAL CONDYLE OF THE FEMUR.

To the Editor of THE LANCET.

SIR,—A very interesting report appeared in THE LANCET of Dec. 12th (p. 1087) by Dr. MacGillivray of a case in which he removed half an Enfield bullet from a deep position in the internal condyle of the femur of a sergeant of the Rifle Brigade, after being lodged there more than thirty years. According to the account given, the man had been wounded in the Crimea while he was with a party who were reconnoitring before Sebastopol, and, shortly after the injury, was removed to the Valetta Hospital. The knee-joint was said to have been opened at the time of the injury, and this alleged fact is contrasted in the report with an observation of mine, published in Holmes's System of Surgery, that "I did not think any instance occurred during the Crimean war in which the synovial capsule of the knee-joint was manifestly penetrated, and the ends of the femur or tibia fractured, where the wounded limb and life of the patient were preserved."

On reading the report I communicated with Dr. MacGillivray, and asked him whether the sergeant's name was not John S——, as I was in possession of some notes of the wound to which his knee had been subjected, written when he was in the Brompton Hospital at Chatham in Sept. 1856. The identity of Dr. MacGillivray's patient, who had asked him not to mention his name when reporting the case, and of the patient referred to in my notes, was sufficiently proved in our correspondence; but, that no source of doubt might remain, the records of the Rifle Brigade have been searched for me at the depôt at Winchester, and the conclusion previously arrived at fully confirmed. The fact is this sergeant was never in the Crimea at all. He received his injury in Malta while at rifle practice, in May, 1856, many months after Sebastopol had fallen, and after the British troops had quitted the Crimea. The sergeant only served two years and four months in the army, and his total foreign service was five months at Malta. He was discharged at Chatham on the 6th of November, 1856, the knee-joint being ankylosed at the time, but there still being a sinus leading down to bone. In giving the history which he did to Dr. MacGillivray, he no doubt thought it would excite more interest in his disability if he traced its origin to military operations in front of an enemy, instead of more peaceful circumstances, such as musketry practice at Malta. Had the man been more intimately acquainted with the state of things in the Crimea, he would not have told his surgeon that he had been injured while his company was reconnoitring before Sebastopol in May, 1855, when all the ground before the place was occupied by the trenches and works of the besiegers; nor would he have said that after the fourth day of the injury, on account of its severity, he had been removed to the Valetta Hospital, instead of to the Castle Hospital at Balaklava or Scutari. All surgeons are liable to be deceived by patients in the histories they give of occurrences long antecedent, and in making these remarks I do not of course intend to attach any blame to the reporter, or in any respect to depreciate Dr. MacGillivray's operation, which was obviously a very thorough and successful one, and of immense service to the patient.

So far as the abstract notes of the case in my possession are concerned, they tend to show that the articulation was not opened at the time of the original injury, but that the lower part of the femur was penetrated from the outer side and posteriorly, and that ankylosis occurred from the results of inflammatory action indirectly induced. Many changes must have occurred in the parts surrounding and adjoining the injured knee during the long interval since his discharge from the army in 1856, owing to irritation arising from the lodged fragment of lead, suppuration, and their consequences, which would make it very difficult at this day to determine the exact nature of the damage done at the time of the original wound. Whether, however, the joint was or was not opened at the time the injury was inflicted, so far as this particular instance is concerned—and this is the chief purpose of my letter, which I send with Dr. MacGillivray's assent—it does not militate against the observation of mine which Dr. MacGillivray quoted, for that observation had reference only to gunshot wounds of the knee occurring in time of war, and, further, under the special conditions which existed at the time of the Crimean war. I need hardly say that I am aware of many cases in which wounds with penetration of the capsule of the knee-joint have been recovered from without amputation under other conditions.

I am, Sir, your obedient servant,
THOS. LONGMORE,
Surgeon-General (R.P.), Professor of Military Surgery.
Netley, Dec. 28th, 1885.

WINTER COMFORTS FOR MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—The setting in of winter weather reminds me of an old promise to write a letter on this subject. Next to food, perhaps few things contribute more to the preservation of health than the conservation of bodily heat. Feeling the importance of the question, and having a lively conviction of the frequency with which the principles of dissipation and storage of heat are violated by English people, I venture to lay before my medical brethren a few hints which may be of value to themselves in the first instance, and indirectly through them to the public. Most medical men visit their patients either on horseback or in an open carriage, or in a brougham or by railway. There is one source of loss of bodily heat common to all classes—viz., the feet. The leather of our boots allows the heat to escape like water through a sieve. Travel as we may, when the temperature is below freezing point, as a rule our feet become cold in a very short time. When the feet are warm the whole body is warmer, and we can more readily bear exposure of the face or hands, no slight matter for those who read or write when travelling. How then are we to keep the feet warm? There are two very excellent methods. The first is the adoption of Dr. Jäger's "Sanitary Boots."[1] They are made of woven woollen material, lined with flannel, soled and tipped with leather. They lace high up above the ankle, and fit easily, so as not to interfere with surface circulation. The other method is the adoption of American snow-boots, which in this district are known as "Jemimas," and are very popular with my medical brethren. They are made of felt throughout, and are shod like a golosh. They are easily put on over ordinary walking boots and are fixed by a buckle. They cost about 7*s.*, and

[1] Jäger Clothing Company, 42, Fore-street, E.C.

Digitized by Google

can be bought at an indiarubber shop. I have given a pair to my coachman, much to his comfort in frosty weather. In a long railway journey, or in walking in snow, their value is inestimable. They are almost equivalent to an additional coat.

A medical man who visits his patients in an open gig or carriage, whenever he enters a house, leaves a warm seat, and on returning in ten or fifteen minutes finds the cushion and rug cold. By the time he reaches the next house the seat and rug are warm again, and out he gets, to let them cool down before his return; in other words, he is perpetually parting with bodily heat, which in severe weather he can ill spare, and is warming up, to very little useful purpose, inanimate material. This may be obviated by having either a hot-water bottle (of stoneware, not of metal), or one of the still more convenient indiarubber hot-water bags with a woollen cover. On his entering a house the warmer is placed on a cushion and is covered by his rug; it is placed at his feet when he returns to his carriage. If he drives in a brougham, or in a carriage in which the driver is not at his side, it is better that the hot-water bottle should be pushed to one side, or kept on the seat, protected by the rug. Such an artificial source of warmth is of more value on the seat than at the feet. To those travelling long distances by railway in cold weather it is often well to place the foot-warmer on a cushion for ten minutes, covered by the rug. This gives a good start. If the journey be at night, say, with a temperature at 20°, and the traveller lies his whole length on the seat, the foot-warmer may be placed edgeways against the back of the seat, and the traveller may lie against it, receiving warmth himself and also retarding the cooling down of the hot water.

Another point akin to this subject is to have a "window ventilator" in the roof of the brougham. This is described at the end of my book, "Dangers to Health." With the roof ventilator open there is no draught, there is no need to have a single ordinary window open, even with two or three persons in the carriage, and the brougham is kept perfectly fresh. The current of air sets steadily outwards through the ventilator when the brougham is "going," except when there is a strong gale from the rear. By this combination of the roof ventilator with a warm seat, a medical man's brougham would tend to preserve, and not, as is often suspected, to impair health.

Let me urge another point upon medical men who are liable to be called up in the night—viz., that they should in severe weather have a fire in their bedroom. When called in the night they should leave their house with plenty of warmth stored up in their clothes, great-coat, rug, &c., and they should not face a chilly night, and perhaps a patient's chilly bedroom, chilled themselves at the start. Keeping this point in view, let them have a fire in their bedroom as soon as cold weather sets in, and let them take care that their fireplace is constructed on right principles. The main points are these:—1. Have no iron at the back or sides, brick or firebrick only. 2. Let the sick lean over the fire, not lean away from it, as is the case with most fireplaces out of ten. 3. Close the chamber [illegible] fire by a movable shield or "economiser." The use of the "economiser" is now becoming well known, and in many towns ironmongers and blacksmiths, have learnt how to make them. With very little trouble a fire can be so [illegible] 11 P.M. as to keep in all night. One pennyworth of coal ought to make a fire capable of lasting eight or nine hours. There is one precaution that should be taken. Seeing that the "economiser" makes the chamber under the grate, and the hearth, hotter, if there is a cracked hearth-stone or doubt whether there be a wooden beam directly under the fireplace, it will be well to have a small ash-pan, rather a grate, from or attached to the "economiser." Given a fire, the place for great-coat and rug would be in the room and before the fire, not in a chilly and often damp entrance-hall.

The knowledge of the properties of heat will supply us with hints to guide us in our management of the sick room. Bearing in mind that radiated heat passes through air without warming the air, to reach objects to which it imparts heat, why do we allow a patient, say with bronchitis, in a room with a bright fire, to lie in a sort of Arctic region of a bed, the radiation of the fire being arrested by a high foot-board, which sometimes gives evidence of the heat it receives by splitting? Let our patient *see* the fire as he lies in bed, and, if necessary, screen the off-side of the bed by a blanket stretched on a clothes-horse, which not only will [illegible] but stores and gives off again the radiant heat of the fire. Another hint let me give about chilly beds. When in Scotland in a cold April, on a fishing holiday, night after night I could hardly get warm in bed. At last I found that the only protection against a rapidly conducting mattress was an extremely thin worn-out blanket. The ample non-conducting upper blankets and rug were of little avail against the rapid loss of bodily heat downward to the mattress. I learnt a lesson, and added a blanket over the mattress, and no more felt the cold.

I remain Sir, yours, &c.,

Leeds, Dec. 19th, 1885. T. PRIDGIN TEALE.

CRIME AND RESPONSIBILITY.

To the Editor of THE LANCET.

SIR,—On Wednesday last, at the Central Criminal Court, Henry Patrick, aged twenty-four, was put upon his trial, convicted without remark by the jury, and sentenced to death, for the "wilful" murder of Rachel Bayley. The circumstances of the crime are not in my recollection, and I cannot, therefore, make any intelligent or useful reference to the mental condition of the criminal at the time when the deed was done, but in the report of the trial it is stated that during its progress the wretched man was seized with a violent epileptic convulsion which interrupted the proceedings for about half an hour, and also that he was again seized in a similar fashion at the conclusion of the sentence. The counsel for the defence stated that his client had been for some time suffering from epilepsy, and urged that he should not be held responsible for his acts. Dr. Morgan, of Clerkenwell Prison, stated in evidence that although the man had had several epileptic seizures, he nevertheless considered him to be a man of sound mind and understanding. Had it not been for this evidence I should have said that the plea put forward by the counsel was an unanswerable one, and that the sentence was monstrous and unjust. The case, however, is one which demands the serious consideration of the authorities. The convict, although young in years, is probably old in the disease which has driven him with ruthless haste into the condemned cell, and which may have been the result of an ignorant rather than a conscious disregard of the unwritten laws of nature. From step to step this unhappy wretch may have descended from the thoughtless innocence of childhood to an equally thoughtless manhood of vicious crime. Perhaps every circumstance of life confirmed and strengthened an inherited criminal tendency. I do not know, as I have said, the circumstances of the crime, and I have the evidence of a medical practitioner who had the opportunity of observing the conduct of the convict for some time, but there seems to me to be a mistake somewhere. A prisoner gives clear and unmistakable evidence to the judge and jury that the machinery of his mind is radically deranged, and that he is suffering from a disease that is certainly at times attended by fits of distinct mania, during the occurrence of which the patient is hopelessly mad, and yet he is treated as a man of sound mind and condemned to death.

The question which arises out of such cases as that of Henry Patrick is of much interest, and great importance. The difficulties that surround it on every side are not easily overcome. Mental science, is, perhaps, of all sciences the most inexact and indeterminate. Our knowledge of the manner in which the machinery of the mind works is, with the exception of a few well-founded facts, indefinite and unsubstantial. For practical purposes the somewhat misty idealism of those who, for lack of a more expressive phrase, may be termed immaterial philosophers, is of little or no avail. What is wanted is an intelligent and careful extension of the scientific examination of material change for the purpose of assigning to each mental expression its material cause. It may be that for a time religious prejudice and superstitious fear will stand in the path of the scientific explorer, but these sentiments must fall before the irresistible force of scientific sense. At present the tests by which a man's soundness of mind is estimated are not trustworthy, because they are founded upon hypothetical assumptions and assertions which have little or no foundation in fact. A man may engage in the ordinary affairs of life, and display a fair amount of intelligence, and yet have moments of insanity when his reason is powerless to control the action of his more animal instincts. In process of time, however, the scientific explorer may

Digitized by Google

discover the physical cause of anger, of hate, and of sensuality. The brain of the man of cool and deliberate action must differ in its intimate physical elements from the brain of the man whose outbursts of passion are notorious, and whose actions are the results of impulses that are often beyond the control of the will. By patient inquiry in practical medicine, pathology, and morbid anatomy, much may be done in the direction of referring each phase of morbid mental action to its physical cause—to some hereditary defect or material change of structure that time and habit have effected. In the case of Henry Patrick there must of necessity be some deviation from the normal structure, some radical defect that interferes at stated periods with the natural movement, not only of the brain, but of the whole nervous machinery by which thought, speech, and action are maintained and directed. The answer to the question as to whether this man should or should not be held responsible for his acts ought not, in my opinion, to depend upon his every-day conduct, but upon a strict investigation into the facts of the disease from which he suffers. This may have already been made. I think, however, it should be laid down as a rule that no man who suffers from a disease which clearly and without doubt implies that his brain is more or less damaged should be held responsible for his acts.

I am, Sir, yours truly,

Bath-street, Glasgow, Dec. 21st, 1885. ROBERT MACPHERSON.

THE GOVERNMENT OF THE COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—As a Member of the Royal College of Surgeons, an disconnected with either the Press or the Society of Members of the Royal College of Surgeons, I should like to make a few remarks respecting the meeting of the Fellows and Members on the 17th ult. First, respecting the charge made by Mr. Brudenell Carter, that the meetings were the outcome of agitations of the Medical Press, I will only say that this statement was distinctly and emphatically refuted at the meeting; and if this refutation is insufficient, I am quite sure the Medical Press is strong enough for its own protection. Secondly, it has been stated by a writer in your journal that when a man takes the Membership of the Royal College of Surgeons of England he pays the fees for the diploma only, and has no more right to a voice in the government of the College than he has in indicating how his butcher or baker should conduct business. This idea is rather crude. But I will endeavour to refute it. If the butcher or baker be a man of respectability, every customer has a distinct voice as to the manner in which business shall be conducted, for if the business is not managed to the satisfaction of the customer, he at once withdraws his patronage and deals elsewhere. Again, when the butcher or baker sells so much meat or bread, the customer is at liberty to deal with it precisely as he pleases. Now, in the case of the diploma of the Royal College of Surgeons there is no analogy. For once a Member, and you are then a Member or Fellow for life, and the College very properly reserves the right of supervising your conduct and the manner in which you degrade or elevate its diploma. Now, if a man can degrade his college, surely he has an equal right to elevate it. Hence it follows that the College clearly recognises the power of its Members to degrade or elevate the College by the manner in which its individual Members conduct business. Deep degradation is usually visited with severe and speedy punishment, frequently too severe. But there are an infinite number of minor ways in which the College is degraded every day, such as shielding unqualified persons, retailing professional skill (?) for sixpence, keeping open retail establishments, making a charge for seeing the poor and needy at our hospitals, and this, too, by those who should set a higher and brighter example, and many other matters which are beneath the notice of the College; all of which minor offences do more to degrade the College and to undermine the position of its individual members than do some of the more serious offences which are usually visited with the rigour of the law. On the other hand, members who elevate the College all over the world by their own personal skill and indomitable perseverance are too frequently passed by without either recognition or reward. Thirdly, Mr. Rivington hit the right nail when he asked the question wherein the superiority of the diploma lay, when the College charged several guineas more for its diploma than do other colleges which convey equal rights and privileges, and often, I may add, superior advantages. Nowadays the value of a thing depends on how much the article will fetch in the open market. It is a notorious fact that a man from over the Border with a double diploma, costing less than the single diploma of the Royal College of Surgeons, which most unjustly entailed a double examination, can command better and more remunerative appointments. And further, without the consent of the Members of the College the Royal College of Surgeons has now combined with the Royal College of Physicians to grant a double diploma, and they seek also to confer the degree of M.D. upon those of their Members who have obtained their conjoint diploma; thereby excluding the 15,000 or 16,000 Members who have already passed the examinations of the College, not only in surgery, but many of them in medicine also. In case the combined Colleges ever obtain the powers to grant the degree of M.D. to their examinees, the time is not far distant when a Member of the Royal College of Surgeons will be practically and legally unqualified. A far more graceful act on the part of the combined Colleges would have been to have conferred the diplomas of the Conjoint Board upon all of the Members of the Royal College of Surgeons or Licentiates of the Royal College of Physicians who could produce evidence of having passed a satisfactory and complete examination in medicine, surgery, and midwifery, such diploma to be conferred without further fee or examination.

I am not one of those who would seek in any way to lower the standard of examinations or the qualifications required for the sweets of office, but the contrary. I would have but one high standard of examination, one fee, and one portal of admission to the profession for each division of the kingdom, and by such means do away with most of those petty jealousies and annoyances which one so constantly hears of, such as, "He is not a regular doctor," or "He's more than a doctor, he's a physician," &c. After all, Mr. Editor, it is not colleges nor universities of universities which make men, but it is men who make colleges, aye, and universities too, all that they ever are, ever were, or ever will be.

I am, Sir, yours truly,

Kennington-park, Dec. 21st, 1885. ALBERT S. MORTON.

"DISEASED MEAT."

To the Editor of THE LANCET.

SIR,—In reply to Professor Walley, of the Royal Veterinary College, Edinburgh, I may say that my authority for the statement that domestic animals produce no sputum is Koch, who says:[1] "Die Thiere produciren bekanntlich kein Sputum, so dass von ihnen während des Lebens aus dem Respirationswegen keine Tuberkubacillen ins Freir geliefert werden." And though I fully recognise the truth of Professor Walley's remarks, I still think that the excreta of domestic animals play a very small part in spreading tuberculosis among human beings. Professor Walley is, of course, specially qualified to speak with authority as to the frequency of tubercular mammitis in cattle. I had not seen Professor Bang's article, and I based my opinion on the statement of Koch:[2] "Da aber Perlsuchtknoten im Enter nicht sehr oft vorkommen." I may also mention that one of the leading veterinary surgeons of this town has for the past year been looking out for a case of tubercular disease of the udder, and has hitherto failed to meet with an undoubted one, though he frequently finds tuberculosis of other organs. I am therefore driven to the conclusion either that tubercular disease of the udder is not very common, or that a capable veterinary surgeon may fail to recognise it. It is not without significance in this connexion that tubercular disease of the human mamma is a very rare affection. Sir Astley Cooper, I believe, described a scrofulous disease of the breast, but I have not been able to refer to his original description. I can find no reference to tubercle of the mamma in the last edition of Holmes' "System of Surgery." In Cornil and Ranvier's "Pathological Histology"[3] the passage occurs: "We know of no example of tubercles occurring in

[1] Koch: Die Ätiologie der Tuberculose. Mittheilungen aus dem Kaiserlichen Gesündheitsamte. Berlin, 1881, p. 81.
[2] Ib., p. 82.
[3] English edition, translated by Shakespeare and Simes, 1880, p. 710.

Digitized by Google

the mammary gland." Payne[4] says: "Tubercle has not been observed to occur in the breast."

While remaining of the opinion that tubercle bacilli and their spores may, and frequently do, pass through a healthy alimentary canal without producing disease, I still recognise (especially since the report of Drs. Klein and Heneage Gibbes' experiments[5]) that the consumption of tubercular flesh involves a risk to which the public ought not to be exposed; and I am only too glad to add my voice to that of Professor Walley in asking for further legislation regarding the sale of milk, and for a more efficient system of meat inspection. The latter will never be attained until public abattoirs are provided in all towns and the numerous and scattered slaughterhouses are abolished.

I am, Sir, yours truly,

Nottingham, Dec. 23rd, 1885. H. HANDFORD, M.D.

ANATOMICAL ANOMALIES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of the 19th inst. your Dublin correspondent notes an instance of a rare irregularity of the vertebral artery—namely, that in which it springs from the transverse part of the arch of the aorta. I have seen three cases of this within the last twelve months in the dissecting-room of Trinity College, the abnormality in each instance occurring in connexion with the left vertebral.

It may, perhaps, not be uninteresting to your readers if I should mention two very rare nervous anomalies which I had the good fortune to come across of late. The first was a case in which the communicans noni arose from the pneumogastric, and may probably be explained by the fact that the branch of communication between the second cervical nerve and the pneumogastric was unusually large. The descendens noni is not unfrequently found arising from the latter, but it is very rare for the communicans to do likewise.

The second is an anomaly which, so far as I am aware, has not been observed before. The nerve to the rhomboids, which arises from the fifth cervical, gave off a slender branch, descended behind the brachial plexus, and supplied the upper digitations of the serratus magnus muscle. As the rhomboid nerve usually gives one or two branches to the levator anguli scapulæ, the above abnormality derives special interest from the fact that in certain of the lower animals the serratus magnus and levator anguli scapulæ form one continuous muscle, the portion which is deficient in man being supplied by slips from the three lowest cervical vertebræ. I am, Sir, your obedient servant,

JOHN P. HENRY, B.A.,

Dublin, Dec. 21st, 1885. Assistant Demonstrator of Anatomy, T.C.D.

"ARTHRECTOMY."

To the Editor of THE LANCET.

SIR,—I notice in THE LANCET of December 26th a remark of Mr. Mayo Robson's, at the Leeds Medico-Chirurgical Society, in a discussion upon so-called "arthrectomy" of the knee. He states that, according to reports of mine, ovasion, as I prefer to call it, succeeded only once in sixteen cases. As I think the operation in suitable cases a valuable one, I desire to correct this statement. In only one instance was a perfect and movable joint preserved, but in five other cases a sound though stiff limb resulted, and two more have since healed; making eight cases in which a result was obtained as good as excision in other ways, and better, in that there is an absence of shortening from removal of bone. These limbs are very difficult to keep straight among the poorer classes; but the same objection applies to excision in young children, and it is as a substitute for excision that I have brought my cases forward. I claim that half my cases have been successful, and in suitable cases the percentage will, I believe, be much greater in the future. My notes were published in the *Medical Chronicle* for July, 1885.

I am, Sir, yours faithfully,

[illegible], Dec. 29th, 1885. G. A. WRIGHT.

[illegible] and Ziemssen's Pathological Anatomy, edited by Payne, 1875, [illegible] of the Local Government Board, and THE LANCET, Nov. 28th, [illegible].

LIVERPOOL.

(From our own Correspondent.)

DEPRESSION OF TRADE AND THE MEDICAL CHARITIES.

THE long-continued depression of trade and commerce has had a very serious effect upon the finances of our local medical charities. The Eye and Ear Infirmary, though most economically conducted, is seriously crippled in consequence of its diminished income, and an urgent appeal has been issued to the public. The same observation applies, with some modification, to all the hospitals, and especially the Royal Southern Hospital.

THE MAYOR AND CHRISTMAS DINNERS.

Alderman David Radcliffe, the re-elected mayor, is repeating the noble munificence he showed last year. One thousand hot pots, each sufficient for a large family, are to be distributed by him, together with three hundred more contributed by friends. These will be given through the Rev. Messrs. Lester and Postance, Father Nugent, and H. G. Brown. Other seasonable gifts will probably follow.

RECENT CASES AT THE CITY CORONER'S COURT.

An inquest was held on the body of a female infant twelve days old, which had died while under the care of a midwife with symptoms of opium poisoning. She was the illegitimate daughter of a widow residing at a distance from Liverpool, and was sent to the midwife to be nursed. This was accomplished, according to her own admission, by feeding it with boiled arrowroot mixed with milk, and, because the child was a very cross one, giving it a drop of laudanum on a piece of sugar. Dr. Leigh, who was called in to see the child, and who subsequently made a post-mortem examination, gave it as his opinion that death resulted from laudanum poisoning. The jury returned a verdict of "Death by misadventure," and censured the mother of the child, as well as the midwife, for their conduct. On the same day, an inquest was held on the body of a newly born male child, found in the coal cellar of a temperance hotel in the north part of the city. A young woman, who had been a domestic servant in the hotel, had been committed for trial on a charge of concealing the birth of an infant whose decomposed body had been found in her box. She had been observed to show signs of advanced pregnancy, and about the 10th ult. there were appearances indicating that she had been recently delivered. On the 1st inst., after her committal, the body of the deceased was found in the coal cellar by the servant who took her place. It was fully matured, and had a man's neck-tie tightly tied round its neck. It was examined by Dr. Wilde, the resident surgeon at the North Dispensary, and subsequently by Mr. F. T. Paul, lecturer on medical jurisprudence, and Mr. F. W. Lowndes, surgeon to the police. From the condition of the funis, the terminal end of which was in a dry, gangrenous state, and the state of the lungs and heart, it was clear that the child had survived its birth some hours; and the appearances of the neck, mouth, and tongue pointed to strangulation as the cause of death. A verdict of "Wilful murder" was returned against the servant.

HEALTH OF LIVERPOOL.

At the last meeting of the Health Committee on the 17th inst., the medical officer (Dr. Stopford Taylor) reported that the death-rate was equal to 24·5 per 1000 of the estimated population. There were 2 deaths from small-pox (one vaccinated and one unvaccinated), 14 from measles, 4 from scarlatina, and 4 from fever. The inquest cases amounted to 17, of which 2 were due to excessive drinking and 3 (under one year of age) to suffocation. The number of uncertified deaths was 11. There were also reported to the medical officer 9 cases of fever, 6 cases of small-pox, and 33 cases of scarlatina. There were on the 17th inst. 50 cases of small-pox in the city hospital.

LADIES' CHARITY AND LYING-IN HOSPITAL.

A bazaar was recently held in aid of this charity, and resulted in the handsome balance of £1594 (after all expenses had been paid) for the building fund. The charity is doing a very useful work among the poor at this inclement season, and deserves every encouragement. By its means poor married women are provided with skilled attendance in their confinements, with certain medical and other comforts, and skilled obstetric assistance in difficult

Digitized by Google

cases. There are wards with twelve beds for the reception of in-patients, and so perfect are the arrangements that all danger of fever is as effectually guarded against as in our present state of knowledge they can be. There is a large out-door department, which comprises the whole of the city, and affords practical instruction to students attending the obstetric class at the Medical Faculty of University College.

Liverpool, Dec. 22nd.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE CORONERSHIP OF NEWCASTLE-ON-TYNE.

THROUGH the death of Mr. J. T. Hoyle, a member of the legal profession, a vacancy has taken place in the office of coroner for the city of Newcastle-on-Tyne. Mr. Hoyle held the office for a long series of years, and was highly respected by all classes of the community. The duties have been performed of late years by his son, who is also a member of the legal profession and is a candidate for the vacant office. The office is understood to be worth, after expenses are defrayed, about £400 per annum, and can be very well filled by a medical practitioner, the inquests as a rule taking place in the evening, and so not interfering with other duties. Besides Mr. Hoyle, I hear that there are three other candidates in the field—namely, Mr. Alderman Barkas, who is not a member of either profession; Mr. Alderman Newton, who is well known and respected here as a practising surgeon; and Mr. N. Hardcastle, who is also a surgeon of long standing here, holding the surgeoncy of the gaol and other important appointments. It is to be hoped, however, that before the day of election one of these gentlemen may retire, and use his influence so as to have the election of a medical coroner carried. There is, I know, a good feeling towards the profession in the City Council, who hold the election in their hands; but it would be well to strengthen this by all legitimate outside influence that can be used, as the legal influence is very strong in the Council. The Council have elected Mr. Hill Motum, the Town Clerk, to hold the office pending the election, which has been fixed to take place on the first week in January next. It is very soon, but the Act of Parliament requires the vacancy to be filled in ten days. It may be remarked that two of the gentlemen before mentioned as candidates will have to resign their aldermanic honours, as the act says that the coronership may not be held by any member of a municipal council. Seeing that the office has been so long held by a lawyer it is thought by many here that it would be but a graceful act for the Council to appoint a member of our profession on this occasion. There is another point which I might allude to—namely, that honours come very tardily to our profession in the north of England. Now, it is very well known that on the occasion of the late Royal visit to Newcastle Mr. Alderman Newton acquitted himself in a way to merit the esteem of all classes of the community. The Council now has an opportunity of showing its appreciation of one of its most esteemed members, and a worthy member of our profession, by appointing Mr. Alderman Newton to an office which has been shown to be eminently adapted to the medical profession.

DURHAM COUNTY HOSPITAL.

Dr. Seeker Walker, son of Dr. Walker, of Wakefield, has been appointed house-surgeon to the Durham County Hospital. The post is one usually coveted by young surgeons. This time, I understand, there were about forty applicants for the post, which was rendered vacant by the resignation of Dr. Robertson; four of this number were selected, and Dr. Walker was chosen by a majority of three votes.

A NEW SUICIDE MANIA.

During the last few weeks there have been several cases of poisoning by matches in our police-courts, and sometimes before the coroner. They have all been in females. The *modus operandi* is as follows: they purchase several boxes for a few pence, cut off the lighting ends, and after steeping these in water make a *haustus* of the solution. The usual symptoms of poisoning by phosphorus set in, and frequently after several hours' extreme suffering death ensues. All the cases seem to have sprung out of one—in the way of imitation—which was very fully reported in our halfpenny newspapers a few weeks since.

Newcastle-on-Tyne, Dec. 30th.

IRELAND.

(From our own Correspondent.)

KELLS UNION.

THE sanitary condition of the Workhouse and Fever Hospital of Kells Union was some time since very bad, and the attention of the guardians was directed to this matter on more than one occasion by Dr. Ringwood, the medical officer. At length, after repeated complaints, a committee was appointed to report on the subject. This committee, after making an inquiry, contradicted the statements of Dr. Ringwood, and recommended that that gentleman should vacate the post he held. On the 21st of last November a meeting of the guardians was held, and a resolution was adopted calling on their medical officer to resign, and in due course the matter came under the consideration of the Local Government Board. That body, having fully considered the subject, wrote on December 12th to the guardians, refusing to ratify the resolution in question. Dr. Ringwood, the efficient medical officer of the Workhouse and Fever Hospital, during his long service has never been accused of neglect of duty, and the only apparent reason given for the action of a majority of the Board of Guardians is that he treated his patients too well, thereby increasing the cost of maintenance of the inmates of the workhouse. This charge of extravagance has proved to be untenable, and it is generally believed that the real reason for the hostile attitude of the guardians is because Dr. Ringwood differs in his political sentiments from the Nationalist members of the Board of Guardians. That he has not been sacrificed at the dictates of a narrow-minded clique must be a subject of congratulation to all law-abiding citizens.

BELFAST MAIN DRAINAGE.

The Bill for Parliamentary powers to carry out the Belfast main drainage system has been lodged, and it is intended that it shall be brought before Parliament early this session. The preamble to the Bill refers to the insanitary condition of the Lagan, and the Corporation of Belfast seek powers to purify the river. In carrying out the necessary works, it is necessary that a weir in the Milewater stream should be removed and placed elsewhere, and that the level of the banks and bed of a portion of this stream should be altered and raised, and that the Corporation should be empowered to take certain tidal or slob lands in Belfast Lough and other lands, and construct the required works. The Corporation also, as the Burial Board for the borough, seek to make bye-laws for the management of their cemeteries and obtain the necessary powers to carry out the requisite works. The Bill, which may be styled the "Belfast Improvement (Purification of the Lagan) Act, 1886," will contain the following heads:—(1) Purification of Lagan and sewerage; (2) buildings; (3) sanitary provisions; (4) infectious diseases; (5) markets; (6) cemeteries; (7) fires; (8) telegraph wires; (9) police; (10) financial.

WOMEN AND CHILDREN'S HOSPITAL, CORK.

A Russian Fancy Fair, of a very successful kind, was held recently in aid of the Building Fund of this hospital, so as to help to pay off a debt of some £600 still due. The institution is admirably worked, and well deserves the support of the charitable.

His Excellency the Lord Lieutenant has approved of an expenditure of £4000 in additions and repairs at Armagh District Lunatic Asylum.

Dr. Mc Causland has been elected house-surgeon to Steevens's Hospital, Dublin. Dr. McCausland is a graduate of Trinity College, and obtained a first gold medal at his moderatorship examination.

Dublin, December 29th.

EGYPT.

(From our own Correspondent.)

EGYPTIAN PHARMACOPŒIA.

THE native hospitals have just had served out to them a small and very complete Pharmacopœia in Arabic and English, and the very needful permission has been obtained from the Government to employ in this little book the metrical system, instead of the very complicated and quite

Digitized by Google

inaccurate weights and measures which are in use in the other Egyptian administrations. The Pharmacopœia is the first of its kind in this country, and contains 104 preparations, which include iodoform bougies and pessaries, and all the approved pills, powders, mixtures, and ointments, including a very favourite aperient of carbonates of ammonia, magnesia, iron and soda, with ginger and liquorice, which the natives have christened "divine powder."

OPERATING THEATRE.

Until this year the operations in Cairo Hospital were always performed in a small room without convenient appliances, on no fixed day, and with a throng of eager students crowding round the table. Improvements have gradually taken place, and now notices of important operations are regularly sent to the hospital staff. Sundays and Thursdays are the appointed days. Tiers of seats for 100 students are railed off at one end of an airy well-lighted room, and hot water and gas are laid on in this and in an adjoining anteroom. Facing the rows of light-brown eager faces of the boy-students, there stand, with head, face, and body closely veiled in white, the midwife and her assistants, presiding over a supply of sponges, bandages, sublimated sawdust bags, and other necessaries; while the professors sit on chairs near the table; the operator and his dressers work unimpeded; an English instrument man stands by to anticipate their wants; and visitors may, if they choose, look across the newly made botanical garden to the wondrous citadel of Saladin, to the rows of windmills which Napoleon built to supply his troops with bread in 1798, or to the hills of rubbish which now alone mark the site of the old capital of Egypt of 1200 years ago.

RECORD OF OPERATIONS.

There are usually 450 patients in this hospital, of whom some 350, including prostitutes, are in the surgical wards, for natives invariably prefer the tangible results of surgery to the apparently less satisfactory treatment of the physicians. The out-patient department also furnishes forty-five new patients every day, of whom many require surgical aid. During the last two months the following operations have been successfully performed by the native surgeons, in addition to several of minor importance: median lithotomy on a man aged thirty-five with four stones, and also on two men aged fifty and thirty-two; bilateral lithotomy on three men, aged respectively sixty-five, forty-five, and thirty-six; necrosis of tibia; three cases of elephantiasis of scrotum; and Lisfranc's amputation through the metatarsus. Dr. Milton's operations are chiefly on women, children, and accidents, and during the same period include the following, which are now doing well: lithotomy on two male children, each under two years; lithotrity, in one sitting, on a man, aged twenty, from whom 915 grs. were evacuated; lithotrity on a female child aged eighteen months, the only difficulty in this case being caused by the impossibility of washing out the bladder owing to its diminutive size; three amputations of thigh, two of leg, and one of forearm; excision of a strumous elbow-joint; removal of a naso-pharyngeal polypus, the size of a very large orange, projecting forwards and hiding a third of the man's face, which was found to be attached to the junction of the frontal and ethmoidal sinuses, and necessitated the cutting away of the upper three-fourths of the nose; vesico-vaginal fistula; recto-vaginal fistula, such cases being very common here among prostitutes who have never become mothers; removal of polypus of uterus; two cases of fibroma removed from the buttock; strangulated hernia in a male child aged three; two cases of tracheotomy for syphilitic laryngitis; excision of small elephantiasis of both vulvæ, of more than a year's growth, in a prostitute, being the fourth case operated upon this year; paracentesis for empyema, with resection of the eighth rib, and subsequent washings out with salicylic lotion; caries of palate, in which the fistulous opening was found to contain two plugs of lint, which had been there for some weeks; and thirteen cases of excision of cervical glands, besides one of femoral and one of axillary glands. These gland operations are very common here, and are undertaken partly to cure the great disfigurement, and partly on account of suppuration and pain caused by pressure on nerves, or to prevent secondary infection. During the last fifteen months there have been 115 such operations, all successful excepting two cases, in which the enlarged glands recurred. The unsuccessful major operations of the last two months have been three in number—namely: A vesico-vaginal fistula, in which the failure was due to a temporary omission of the catheter. An amputation at the hip-joint in a convict, six hours after a mass of stone, in a blasting operation, had laid bare Poupart's ligament, fractured the femur just below the great trochanter, wounded the femoral artery, and traversed the fleshy part of the leg like a fragment of a Krupp shell; he lost no blood during the operation, but died of collapse an hour afterwards. The third case was a man, aged twenty-six, with a greatly enlarged but not pendulous thyroid gland, causing alarming attacks of dyspnœa, which necessitated operative interference. The isthmus was divided by double ligature and thermo-cautery, and this was followed on the second day by extreme enlargement and congestion of the halves of the divided thyroid, which, though temporarily relieved by three dozen leeches, produced continued obstruction of breathing, and suddenly caused death on the fifth day after the operation, while preparations were being made for tracheotomy. At the necropsy great pulmonary congestion and pneumonia were recorded, while the thyroid was extremely vascular, and contained much new inflammatory tissue.

PAPYRACEOUS FŒTUS.

An Egyptian woman was brought to the hospital by the police three weeks ago with a history of having being kicked by her husband while in her eighth month of pregnancy. Accompanying her was a paper parcel containing (1) the body of a dead male child, small and well nourished, which had lived for a few hours; (2) a round, flatly-compressed placenta, with a diameter of three inches, attached by a tape-like cord to (3) a perfectly flattened papyraceous fœtus four inches in length. The placenta and cord which had been attached to the full-grown child were not brought to the hospital. There was no history of accident or otherwise to account for the death of the fœtus *in utero*.

ROYAL VISIT TO HOSPITAL.

H.H. the Khedive, attended by his suite, made an official inspection of Kasr-el-Aini Hospital this morning, being the first time that he has done so since his praiseworthy visits during the cholera of 1883. His Highness was so pleased with all he saw that he sent for Dr. Milton to the palace in the afternoon, and, with many laudatory words, decorated him with the order of the Osmanieh of the Fourth Class. This unexpected mark of approval has given the greatest satisfaction to both Europeans and natives.

Cairo, Dec. 1st.

THE SERVICES.

Deputy Surgeon-General J. O'Nial, Principal Medical Officer of the Army of Occupation, has proceeded up the Nile to join the staff of General Stephenson at the front.

WAR OFFICE. — Army Medical Staff: Surgeon-Major Thomas Jerram Orton has been granted retired pay, with the honorary rank of Brigade Surgeon; Surgeon Michael Edward FitzGerald resigns his commission.

INDIA OFFICE.—The Queen has approved of the retirement from the service of the undermentioned officers of Her Majesty's Indian Military Forces:—Brigade Surgeon Thomas Beaumont, M.D., of the Madras Army; Surgeon-Major George Grant, of the Bengal Army; Surgeon-Major Edwin Clement Bensley, of the Bengal Army; and Surgeon-Major John William Strong, of the Madras Army.

The under-mentioned officers have been granted a step of honorary rank on retirement:—Brigade Surgeon Robert Rouse, of the Bengal Army, to be Deputy Surgeon-General; Surgeon-Major George Grant, of the Bengal Army, to be Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Surgeon John Ottley, to the Cape of Good Hope Hospital; Joseph D. M'Feely, to be Surgeon and Agent at Killybegs; Fleet-Surgeon Henry N. M. Sedgwick, to the Portsmouth Yard; Fleet-Surgeon James J. O'Malley, to the *Excellent*; and Fleet-Surgeon Ernest D. E. Winter, to the *Indus*, additional, for the *Woodcock*.

Surgeon Adam Garratt Mitchell has been appointed to the *Rohilla*, Peninsular and Oriental Company's Service.

ENGINEER VOLUNTEERS.—1st Gloucestershire: Surgeon William Fitzwilliam Carter resigns his commission.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion (the Lincolnshire Regiment): James Pickering Stewart, Gent., M.B., to be Acting-Surgeon.

Obituary.

SAMUEL SUMNER DYER, M.D. ST. AND., L.R.C.P.L., &c.

WE have to record the death of this well-known and most estimable member of our profession, which occurred on Sunday, Dec. 20th, after a short illness. Samuel Sumner Dyer was born in 1823 in the house where he died, being the eldest son of the late Mr. Thomas Dyer, who had practised his profession for a period of forty years in the town of Ringwood. He received his general education at King's College, entering the medical school in 1843, when King's College was at its zenith, under the auspices of such teachers as Budd, Todd, Fergusson, Bowman, and Simon. This year was marked by the number of students who afterwards distinguished themselves, and amongst them Dyer was noticeable for devotion to his studies and for his high character. After having obtained his surgical diploma, he was elected to the post of house-surgeon to the hospital, and in that office he gained that practical knowledge of which he made such good use in after life. As soon as he had completed his education, he joined his father at Ringwood. When the latter died, some few years afterwards, he conducted, with the help of an assistant, the whole of the practice of the town and of the neighbourhood for many miles around, working laboriously day and night, and devoting the whole of his energies to the arduous duties of his profession for a period of more than twenty years, when he was joined by his brother, Dr. Henry Dyer, by which event his labours were somewhat lightened. During this period his reputation had become established to such a degree that he was consulted by all around, rich and poor, and in cases of difficulty and urgency his opinion and advice were repeatedly sought by his medical brethren in the neighbouring towns. He was the very type of what a good provincial practitioner should be. He was a sound physician, a well-practised obstetrician, and a skilful surgeon, particularly evincing the qualities of the latter in the large number of severe operations which he performed with great success, his skill and dexterity being the result of the teaching of his old friend and master, Fergusson, who took much and especial notice of Dyer whilst a pupil at King's College. Although his time was so much absorbed in the duties of his large practice, Dr. Dyer was enabled to keep pace with the times and to make himself well acquainted with the improvements in medicine and surgery. He made a point of snatching a brief holiday every year for the purpose of attending the annual meetings of the British Medical Association and of the branch meetings, at one of which he was lately president. Apart, however, from the professional aspect, Dr. Dyer was endowed with qualities which gained the esteem and affection of all who came in contact with him. Possessed of a singularly gentle and amiable temper, he was rarely ever known to say a harsh word to anyone; and yet when occasion occurred he was firm of purpose and strictly regardful of truth and justice. All these qualities were enhanced by his strong religious faith. A firm believer in the truths of Christianity, he preached its precepts in his daily life simply, steadfastly, yet without the least ostentation; and it is not to be wondered at that his influence on all around him was very great. In all matters connected with the town and its neighbourhood, civil and religious, he took the most prominent lead, and it will be difficult to fill the wide gap which his loss has occasioned. Death smote him literally "like a thief in the night," for he retired to rest on the night of Tuesday, the 15th, and was found shortly afterwards suffering from the symptoms of hæmorrhage in the brain. He lingered until the 20th, when he passed away. He was assiduously attended to by his brother, Dr. Henry Dyer; his old friend and former pupil, Dr. Wyke Smith, of Wimborne; Dr. Lush, of Weymouth; and his old fellow-student and friend, Mr. Henry Smith, of King's College.

Dr. Dyer married the sister of the late Dr. Monckton of Maidstone, who died a few weeks ago, but left no issue.

The funeral of Dr. Dyer took place on the 24th ult., and was of a most impressive character. The whole town was in mourning, and, although it was Christmas-eve, business was almost entirely suspended. The fine old and spacious church was crowded by a large concourse of the inhabitants of the town and its neighbourhood, of every grade of life. The service in the church was most effectively rendered by the vicar, assisted by several of the neighbouring clergy and a full choir. From thence the procession, accompanied by large numbers of people, moved on to the cemetery, where the interment took place, the coffin and the edges of the grave being covered and surrounded by a mass of beautiful wreaths. Many professional friends were present, some coming from long distances to pay this last token of respect to the memory of their lamented colleague; and it was impossible for those assisting at the ceremony to resist the conviction that the great gathering around them was not only a tribute to the worth of him whom they were mourning, but that it was a mark of appreciation of the profession of which the late Dr. Dyer was so truly an ornament.

R. W. GREENISH, F.R.C.S.

MR. GREENISH, whose early death after a tedious and often very painful illness we have to deplore, was in the active practice of his profession in the north of London. He commenced his studies at University College Hospital in 1872; these were interrupted for six months by a very severe attack of blood-poisoning. He passed his M.R.C.S. in 1876, and in the same year became L.R.C.P. Lond. He held successively the offices of obstetric assistant, University College Hospital; resident clinical assistant, Consumption Hospital, Brompton; junior house-surgeon, Huddersfield Infirmary; and house-surgeon, Ashton-under-Lyne Infirmary. In the autumn of 1881 he went to Vienna, and for twelve months worked at normal and pathological histology under Professor Weichselbaum, and also attended courses of lectures and demonstrations on pathology by Dr. A. Zemann. At this time he published, in conjunction with Professor Weichselbaum, two papers of scientific research: "Ueber das Adenom des Leber," and "Ueber das Adenom der Niere." In 1883 he contributed to the *Journal of Anatomy and Physiology* a "Case of Primary Sarcoma of Pleura," and subsequently a series of papers on the "Outlines of Pathology and Pathological Anatomy" to the *Medical News*. His last illness, which depended upon the secondary results of renal calculus, interfered greatly with his professional occupation, to which he was much devoted, for the last two years of his life. He struggled manfully, however, against these difficulties, and showed remarkable fortitude under the distressing circumstances arising from the disease from which he suffered. Several days before the attack proved fatal he expressed a wish that a post-mortem examination should be made to elucidate some doubtful points in his own case, which he had narrowly watched, and this was his last contribution to the science he loved so well.

JAMES GORDON, M.A., M.D.

ON the 23rd ult. the death occurred, after a short illness of Dr. James Gordon, of Old Aberdeen. Deceased studied and graduated as Master of Arts at King's College, and subsequently studied medicine at Edinburgh and Paris, at the former of which universities he took the degree of M.D. in 1833. Previously to this, in 1831, he had obtained the licence of the Royal College of Surgeons. Dr. Gordon was medical officer to the Oldmachar Parochial Board, and enjoyed the highest confidence of the poor in the district of which he had supervision. He was connected with several public institutions in Old Aberdeen, and, besides acting as town councillor, had held the position of Provost. He was greatly respected by all with whom he was brought into contact, and his death, which occurred in the seventy-sixth year of his age, is much regretted.

TREATMENT OF EPILEPSY.—The prize of 8000 francs offered by the Belgian Academy of Medicine for an elucidation by clinical facts of the pathogenesis and treatment of diseases of the nervous centres, and principally of epilepsy, has not been awarded; but a sum of 500 francs is offered by way of encouragement to the author of the essay bearing the motto, "Traditionem pondero, doctrinam respicio, sequor veritatem," on condition that he allow his essay to be printed in an abridged form with the criticisms of the Commission.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the recent B.S. examination for Honours:—

FIRST CLASS.

Berry, James (Scholarship and Gold Medal), St. Bartholomew's Hospital.
Robinson, Henry Betham (Gold Medal), St. Thomas's Hospital.
*Price, Alfred Edward, Guy's Hospital.
Carr, John Walter, University College.

SECOND CLASS.

Green, Charles David, St. Thomas's Hospital.
Targett, James Henry, Guy's Hospital.
Brock, James Harry Ernest, University College.

THIRD CLASS.

Hinds, Frank, University College.

* Obtained the number of marks qualifying for a Gold Medal.

SOCIETY OF APOTHECARIES.—The following gentleman passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise, on Dec. 24th:—

Mariette, Ernest P. Alphonse, St. Stephen's-square, Bayswater.

The following passed the examination in the Science and Practice of Medicine, and received certificates to practise:—

Adye, W. J. Alexander, M.R.C.S., Bradford-on-Avon, Wiltshire.
Cottell, R. J. Cope, M.R.C.S., Cheyne-row, Chelsea.
Burns, Alfred Hugh, Caroline Villas, Hanwell.

THE late Mr. Vanderbilt's bequests include one of $100,000 to St. Luke's Hospital, and one of $50,000 to the Home for Incurables.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The library of this institution will be closed on Tuesday, Wednesday, Thursday, and Friday, the 5th, 6th, 7th, and 8th of January, for the purposes of the examinations.

LADY DOCTORS IN ITALY.—The first official recognition of female medical practitioners has just been made in Rome. The recipient of this distinction is Signorina Terne, M.D., whom Queen Margherita has appointed one of her physicians in ordinary.

ROYAL MEDICAL BENEVOLENT COLLEGE.—On Thursday, January 7th, at 7.30 P.M., a special service will be held at the Church of St. Mary Bishophill Senior, York, when a sermon will be preached by the Venerable Archdeacon Blunt, D.D., and a collection made on behalf of the Epsom College.

SANITATION AT SOUTHAMPTON.—The important sanitary works recently sanctioned by the Corporation of Southampton, involving the erection of the new destructor works at Chapel for the cremation of the town refuse and the treatment of a large section of the sewage of the borough by precipitation, were successfully inaugurated on Dec. 11th.

RUSSIAN REMEDY FOR HYDROPHOBIA.—The alisma, or water plantain, is lauded in Russia as a remedy for hydrophobia. The plant flowers during the summer, and should be collected during August. The roots must be dried and grated, then spread on bread and butter, and a good dose taken night and morning. Two or three doses are said to be sufficient to effect a cure.

SUICIDE OF A PHYSICIAN.—On the 29th ult. an inquest was held at Kensington, on the body of Henry Wotton, M.D., who died on Christmas Day, under distressing circumstances, from the effects of a self-administered dose of prussic acid. After hearing the evidence of several witnesses the jury returned a verdict of "Suicide whilst in a state of unsound mind."

THE HOSPITALS ASSOCIATION.—The second general meeting of the Session 1885-6 was held on Dec. 16th, 1885, at the rooms of the Social Science Association, 1, Adam-street, Adelphi, W.C., Dr. Bristowe, F.R.S., in the chair, when a paper by Mr. G. Sturge, on "The Use of Alcohol in Hospitals," was read by Mr. Burdett (Mr. Sturge being unable to be present), in which was indicated the urgent need of attention to the diet tables of hospitals, on account of economy, and much more in order to overcome the [illegible] in the present hospital practice that [illegible] drinks contribute to health. It is well [illegible] Mr. Sturge, that in the General Provident Life [illegible] they have two classes of insurers, one class [illegible] alcoholics, the other non-abstainers. From the published statistics from 1866-1882 of this institution, according to the ordinary tables of mortality, 2644 deaths should have taken place, but only 1861 occurred in the Abstaining Section; while of 4408 expected deaths in the Non-abstaining Section, 4339 took place, or only 69 less, or 1·2 less than the expected result. In the opinion of the author the time has come in which the Hospitals Association might profitably consider whether any hospital, supported by charity, could be justified in applying its funds to buy alcoholic luxuries for the use of its doctors, servants, or patients.

MEDICAL MAGISTRATE.—Mr. A. R. Ticehurst, M.R.C.S. L.S.A., has been put upon the Commission of the Peace for the borough of Hastings.

EDINBURGH FEVER HOSPITAL.—The Public Health Committee, who have the charge of the city Fever Hospital, have recommended the Town Council to appoint a visiting physician for that institution. This is to be a preliminary step towards a permanent arrangement for clinical instruction in fevers, the necessity for which has been lately urged by the various medical authorities, in memorials addressed to the Town Council.

DEATH WHILE UNDER CHLOROFORM.—An inquest was recently held at Newcastle-on-Tyne, touching the death of a young man who died suddenly on the 19th ult. after undergoing an operation on his eye. Dr. Heath, who performed the operation, having given evidence, the jury returned a verdict to the effect that deceased died from failure of the heart's action, after undergoing an operation under the influence of chloroform.

PRESENTATION.—On the 24th ult. at Bridge of Allan Dr. Paterson was presented with a cheque for £340 enclosed in a silver casket bearing the following inscription:—"Presented to Dr. Alexander Paterson, along with a cheque, given by 260 subscribers over the whole country, in testimony of their regard for him as a successful physician, a kind friend to the poor, and a public benefactor to the inhabitants of Bridge of Allan."

HACKNEY MORTUARY.—On the 23rd ult., during an inquest which was being held at Hackney, the coroner, the medical witness, and the jury complained of the disgraceful accommodation provided at the mortuary, one of the speakers stating that in his opinion it was not fit for the backwoods of America. The coroner advised that the attention of the medical officer of health for the district be called to the matter.

A VICIOUS APPETITE.—On the 28th ult., at an inquest held at the Earlswood Asylum for Idiots, on the body of a man who died in that institution on the 23rd ult., it was stated that a post-mortem examination of the deceased showed the stomach to be very much enlarged, and in it was discovered a large roll of foreign substance, consisting of human hair, horse hair, and cocoa-nut fibre, and a few dead leaves, the whole weighing two pounds and a quarter, and completely blocking up the stomach.

THE MADRAS VICTORIA CASTE HOSPITAL.—The temporary buildings of this institution, which is intended for the reception and treatment of Caste and Gosha women, were formally opened on the 8th ult., by Mrs. Grant Duff. A grant has been made to the hospital by Government, and the donations already amount to over 100,000 rupees. The lady superintendent is Mrs. Scharlieb, under whose supervision careful arrangements have been made for respecting the feelings of the patients by the strict maintenance of their caste or gosha.

CLINICAL SOCIETY.—The subjoined list gives the names of those gentleman who have been proposed for election as officers and members of Council for the ensuing year:—President: Mr. Thomas Bryant. Vice-Presidents: Dr. James Andrew, Dr. Cayley, Dr. Wilks, Mr. Sydney Jones, Mr. Thomas Pickering Pick, and Sir Henry Thompson. Treasurer: Mr. Christopher Heath. Council: Dr. Carrington, Dr. Coupland, Dr. Drewitt, Dr. William Ewart, Dr. Hadden, Dr. F. de Havilland Hall, Dr. Felix Semon, Dr. Tyson, Dr. John Williams, Mr. Henry Hugh Clutton, Mr. Davies-Colley, Mr. Harrison Cripps, Mr. Clinton T. Dent, Mr. A. Pearce Gould, Mr. Warrington Haward, Mr. Henry Morris, Mr. Walter Rivington, Mr. John Wood, F.R.S. Honorary Secretaries: Dr. Stephen Mackenzie, Mr. Rickman Godlee

MARY MAGDALEN HOSPITAL, ST. PETERSBURG.—At a meeting of the German Medical Society of St. Petersburg, Dr. Lingen mentioned some statistics of the practice of the Mary Magdalen Hospital during the four summer months of 1885. There were 124 cases of typhus, the mortality of which was 12·2 per cent. The mortality of typhoid was 13·4. Both these rates were below those for the corresponding period of the previous year. The number of cases of pneumonia was 54, though in the previous summer it had been only 33. The mortality was, however, only 9·6 per cent., against 13 per cent. in the summer of 1884. Ninety-five cases of phthisis were admitted, with a mortality of 44·4 per cent., the deaths from this cause accounting for a third of the total deaths. There was no diphtheria. A case of acute glanders was fatal on the tenth day. A case of malignant pustule on the chin was cured by excision and subsequent cauterisation. In the surgical wards there were 283 cases, mostly injuries, wounds, and fractures. The mortality in this department was 5 per cent.

LYNES, JOHN, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to Charing-cross Hospital.

MAY, FREDERICK, L.A.H.Dub., has been appointed Medical Officer for the South District of the Stratton Union, vice Stuart.

PARKER, GEORGE, M.A., M.D.Camb., M.R.C.S., has been appointed House-Surgeon to the Paddington-green Children's Hospital.

POLSON, JAMES RONALD, L.R.C.P.Lond., M.R.C.S., has been appointed Assistant-Surgeon to the Worcester Friendly Societies' Medical Association.

ROULSTONE, WILLIAM, M.D., M.Ch.Q.U.I., has been appointed Medical Officer to the Workhouse, Wakefield Union, vice Horsfall, resigned.

STEDMAN, F. OSMUND, M.R.C.S., L.S.A.Lond., has been appointed House-Physician to Charing-cross Hospital.

WALKER, H. SECKER, M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Durham County Hospital, Durham, vice Murray Robertson, M.B., resigned.

WETHERED, FRANK J., M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed House-Physician to the London Hospital.

WILSON, JOHN, L.R.C.P., L.R.C.S.Ed., has been appointed Medical Officer of Health for the Pudsey Urban Sanitary District, vice Mumford.

WILSON, THOS., M.D.Lond., B.S., M.R.C.S., has been appointed House-Physician to the National Hospital for the Paralysed and Epileptic, Queen's-square, W.C.

WINTER, J. T., M.R.C.S., has been appointed Junior House-Surgeon to the Ancoats Hospital, Manchester, vice W. Arnold, resigned.

Births, Marriages, and Deaths.

BIRTHS.

EMBLETON.—On the 22nd ult., at St. Wilfrid's, Bournemouth, the wife of Dennis C. Embleton, L.R.C.P., M.R.C.S., of a daughter.

INKSTER.—On the 27th ult., at Fulwood-road, Sheffield, the wife of S. Macaulay Inkster, M.D., of a son.

LAING.—On Nov. 29th, at The Adyar, Madras, the wife of Surgeon-Major Jas. Anderson Laing, of a daughter.

SMITH.—On the 25th ult., at Cedar Lawn, Burbage, Hinckley, Leicestershire, the wife of R. Bradshaw Smith, Surgeon, of a daughter.

THOM.—On the 29th ult., at High-street, Crieff, N.B., the wife of Alex. Thom, jun., M.A., M.D., and C.M., of a son.

MARRIAGES.

BARRETT—GLASSFORD.—On the 23rd ult., at 13, West Prince's-street, Glasgow, by the Rev. John Orr, Tron Church, assisted by the Rev. Dr. Cameron, of Dunoon, William H. Barrett to Kate, second daughter of the late A. M. Glassford, Liverpool and London.

DALLAS—READ.—On the 30th ult., at the Oratory, Brompton, by the Rev. J. B. Rowe, assisted by the Rev. A. D. Beste and the Rev. S. Bowden, John Henry Langford Dallas, Esq., R.A., to Emma Jane, second daughter of S. Laurence Read, Esq., of Petersham-terrace, Queen's gate.

FRANKS—BROMHEAD-BUTT.—On the 23rd ult., at St. Philip's Church, Earl's-court, S.W., Kendal Franks, M.D., of Fitzwilliam-square, Dublin, to Gertrude Jane, fourth daughter of the late Colonel T. Bromhead-Butt, 79th Highlanders.

GRAYLING—CHRISTIAN.—On the 22nd ult., at St. Mary Magdalene's, Munster-square, Frank, only son of John Grayling, M.D., Sittingbourne, to Mary Maud, widow of the Rev. R. Cuthbertson Christian, M.A., late of Rossory, Co. Fermanagh, Ireland.

[illegible]NEY—BRAITHWAITE.—On the 29th ult., at the Friends' Meeting-house, Mercers-road, Holloway, N., Willis Norton Whitney, M.D., a member of the United States Legation at Tokio, Japan, to Mary Caroline, third daughter of Joseph Bevan Braithwaite, of Camden-road, N., and New-square, Lincoln's-inn, Barrister-at-law.

DEATHS.

[illegible].—On the 23rd ult., after a short illness, at his residence, Fisher-gate, Preston, Richard Allen, M.R.C.S., and Surgeon-Major to the Royal North Lancashire Militia, youngest son of the late Barten Fletcher Allen, of Preston.

CROFTS.—On the 28th ult., at Church Gresley, Burton-on-Trent, Ellen, the beloved wife of William Carrick Crofts, M.R.C.S., &c., aged 57.

[illegible]MAN.—On the 21st ult., at Priory-road, Kilburn, Henry Pettener Freeman, M.R.C.S., L.S.A.Lond., formerly of Fulham, aged 66.

GREENISH.—On the 26th ult., after a short illness, with much suffering, Robert William Greenish, F.R.C.S., of Somerfield-road, Finsbury-park, second son of Thomas Greenish, of New-street, Dorset-square, in his 33rd year.

[illegible].—On November 5th, at his residence, 2, Oxford-street, Oldham, Robert Bryden Hill, M.D., B.Sc.Edin., aged 32.

[illegible]ON.—On the 26th ult., at South-hill, Bromley, Kent, Francis Jackson, Surgeon, formerly of Guildford and Chertsey, aged 75.

[illegible].—On the 26th ult., at Bognor, Sussex, after a short illness, Mr. Charles Osborn, in the 76th year of his age.

[illegible].—On the 26th ult., at his residence, Lincoln, James Marr Snow, M.R.C.S., L.S.A.Lond., aged 77.

[illegible]ON.—On the 26th ult., suddenly, Henry Wotton, M.D., of Notting-hill-terrace, eldest son of the late Henry R. Wotton, Esq., of Devonshire-square, aged 49.

[illegible] A Fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, January 4.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M. Also on Thursdays at 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

MEDICAL ETHICS IN THE ORANGE FREE STATE.

A CORRESPONDENT writes us that in twenty-seven years' practice at home and abroad he has always been on the best of terms with his brother practitioners. We congratulate him on such a fact, creditable alike to him and to the profession to which he belongs. He has now, however, to complain of unprofessional methods in a medical brother, who thinks it right to foist his advice and medicines on the patients of other practitioners, offering them even for nothing at first. We cannot believe that such practices will be persisted in or that they will be found to succeed. They are entirely undignified and unjustifiable.

It is never too late to Learn.—1. Our correspondent must be aware that there have been many theories put forth to account for the origin of chronic rheumatism, and that pathologists are not agreed as to the existence of a definite poison in the disease.—2. Massage seems to be the prominent feature of the treatment employed by the specialist mentioned.

Mr. J. Jeffery.—It would be contrary to our rule.

DIPHTHERIA AND DEFECTIVE DRAINAGE.

To the Editor of THE LANCET.

SIR,—It would seem to me to be very foolish to ignore altogether the idea that road-level sewer ventilators may have something to do with the various outbreaks of diphtheria simply because certain defects may have been found in some of the houses where the disease has arisen, and because sewer ventilation acts as a kind of safety valve to the house drainage; and, moreover, oxygen is one of the best antiseptics known. I can say, without fear of contradiction, that some of the worst cases of diphtheria in this neighbourhood have arisen at different times opposite some of the worst of these stinking ventilators, and many a time have the persons residing near them had to close their windows when the wind has been blowing in a certain direction. No doubt, where the sewers have all been laid upon properly graduated levels, and there is consequently no stagnation of sewage, these road-level ventilators act perfectly well; but where the levels are altogether irregular it would seem to me that the only safe method is to run shafts up the sides of a certain number of houses, and so convey the effluvium into the upper air. If these road-evel ventilators are not a nuisance and a danger, why have the uthorities gone to the expense of making fresh openings in the centres of the roads when they could so easily have untrapped the gratings which carry off the rain-water at the sides? In conclusion, I would say that one of our chief London consultants told me he had distinctly traced some cases of diphtheria in the north of London to these road ventilators. Such being the case, there can be no question that fresh inquiry is needed. I am, Sir, your obedient servant,

Surbiton, Dec. 28th, 1885. F. P. ATKINSON.

AMOY PRESBYTERIAN MISSION HOSPITAL.

IN the report of the Mission Hospital at Amoy, by Mr. Archibald Macleish, M.A., M.B., C.M., for the past year, an interesting account of various cases, surgical and medical, is given, from which we extract the following as an instance of a not very common affection—viz., lymphocele:—

> "The patient had a collection of milky fluid in the tunica vaginalis, presenting the microscopic characters of chyle, coagulating quickly, and containing large numbers of active filariæ (filaria sanguinis hominis). He was thrice tapped. The first time eight ounces of this fluid were drawn off, and no injection made. The fluid rapidly accumulated, and eighteen days later the same quantity was removed, and a drachm of pure, liquefied carbolic acid injected, causing considerable pain and faintness. The fluid again accumulated, though more slowly. Twenty-six days later five ounces were drawn off, and eighty minims of carbolic acid injected, with only slight pain and no inflammatory reaction. Four months later the testicle was much reduced in size, and when last seen (about ten months after the last operation) was almost normal. Presumably, obliteration of the sac had taken place. The collection of fluid had always been larger in the evening than in the morning, and in summer than in winter. The glands in the groins were not enlarged; and the patient had never suffered from fever, or anything pointing to constitutional disturbance from the presence of the filariæ, which were found also in the blood."

This is the second case of filarious lymphocele that Mr. Macleish has treated. In the previous case, on tapping the second time, sufficient inflammatory reaction was set up, without injection of the sac, to effect obliteration and cure. During the ten months and a half the hospital and dispensary were open 1665 individuals received treatment. On these, 113 surgical operations were performed. The average number of visits to the dispensary by each patient was about five, which, as a Chinaman expects to receive manifest benefit from his first visit, and if he does not get it is but little inclined to persevere, tends to show that the results were very satisfactory.

Mr. J. West Walker should apply to the Volunteer department, War Office.

"PERSISTENT CONSTIPATION."

To the Editor of THE LANCET.

SIR,—I beg to thank all those gentlemen who kindly gave me through THE LANCET the benefit of their advice in the treatment of the above disease. Having adopted Mr. Blenkarne's prescription, I am glad to say that it has, so far, proved successful.—I am, Sir, yours obediently,

December, 1885. PHYSICIAN.

To the Editor of THE LANCET.

SIR,—Having read an excellent annotation on "The Treatment of Constipation" in your issue of Dec. 12th, I beg to ask you to kindly supplement it with a list of aperient vegetables and fruits (obtainable at this season) that are most useful in this obstinate and common ailment.

I am, Sir, yours faithfully,

Dec. 18th, 1885. ADSTRICTUS.

*** Every kind of green vegetable obtainable at this season is of use in relieving constipation. Vegetable soups are particularly appropriate. Among fruits, pears, apples, prunes, and figs are the most effectual, whether cooked or in the raw state. The infusion of preserved tamarinds is doubly valuable from the action of the fruit and from the volume of fluid thus introduced. It also forms a very agreeable drink. It should not be forgotten that, in order to obviate a costive habit, these various substances must, one or other of them, alternately if desired, be habitually taken. In addition to the means recommended in our recent annotation, we may mention that benefit is often derived from friction and massage of the abdominal walls.—ED. L.

THE MEETING OF DEC. 17TH, 1885, AT THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—May I ask the favour of a correction of your report of the above meeting? Your reporter, possibly from failing to catch the word "not," and in his laudable endeavour to compress my remarks, has made me say the opposite of that which I did actually say. I quote from your report, inserting in brackets the words necessary to make my meaning clear:—"It had been said that the College was [not] simply a corporation [that it was something more], but from that he ventured to dissent. It was a body having [high and noble objects and] great responsibilities both to the profession and to the public, [but still nothing but a corporation, and as such the creature of the Charter which created it]." These remarks were directed against certain mischievous delusions which appeared to prevail in the minds of a number of members—namely, that the Council could if they pleased set aside their Charter; that they ought to do so at the bidding of the members; and that on the present occasion they were, as one speaker expressed it, sheltering themselves behind their Charter. The misprint at the end of my remarks of "qualified himself to become," instead of *by becoming* "a Fellow," is so obvious as scarcely to require notice.

I am, Sir, yours obediently,

St. James's-square, S.W., Dec. 26th, 1885. WILLIAM HAUGHTON.

THE NEWARK BOARD OF GUARDIANS.

MR. CHARLES IRVING was elected for the Foster District of the Newark Union, in spite of a strange speech by the clerk of the board on the absence of his diplomas. Mr. Irving is a duly registered practitioner; the locality of his diplomas is quite irrelevant.

House-surgeon.—It is certainly customary for the coroner's officer to give notice to the authorities at infirmaries when inquests are going to be held at such institutions. We imagine in the cases referred to by our correspondent the failure must have been from inadvertence, and not intent. It is highly desirable that the resident surgeon of an infirmary should be called to give evidence concerning the deaths of inmates who have died whilst under his care.

J. F.—Our correspondent is entitled to dispense his own medicines, like every other registered practitioner.

Mr. E. Donaldson.—Yes, in an early number.

MISCARRIAGE; DECAPITATION.

To the Editor of THE LANCET.

SIR,—The following case will perhaps be considered sufficiently interesting to merit insertion in your columns.

On the 12th inst. I was sent for at 4 P.M. to see a lady who was then being attended by a midwife. On my arrival I found a young woman, aged twenty-one, primipara in her sixth month, being threatened with miscarriage. I was asked for my opinion, but not requested to take charge of the case. I gave my opinion that the miscarriage would surely occur, and to have the midwife (who lived close by) at hand. I retired, and at midnight I was called again, and was told by the messenger that a foot of the child was born, but no more. On reaching the house the midwife informed me that the child was born "all but the head," that it was a foot presentation, and that when the head was about being delivered "the patient gave herself a sudden jerk and the head went back." I thought it strange that there should have been any delay in delivering the head of such a small-sized child, but lost no time in asking questions, and immediately examined into the state of the affair. I found the headless body of the child on the bed, the cord protruding from the vagina, and on introducing my hand found for a presentation the foramen magnum, with the placenta in immediate contiguity. When my hand was well introduced into the os, a pain supervened, and the placenta came away. I kept my hand in the uterus and got the head pretty well into my palm, and delivered it. Not being present at the time the body was delivered, I cannot say anything about the "jerk" referred to, but I think the mother was hardly responsible for it.

I am, Sir, yours truly,

CHARLES J. S. DIGGES, M.R.C.S.

St. Louis, Mo., U.S.A., Oct. 29th, 1885.

Alpha.—Our correspondent does not tell us his previous or usual professional relation to the lady in question, or that of the gentleman called in after him, but he seems to have been treated with scant respect.

Lympthill has not enclosed his card.

HOSPITAL ACCOMMODATION FOR RESIDENT MEDICAL OFFICERS.

To the Editor of THE LANCET.

SIR,—The question of proper accommodation for men holding honorary appointments in our hospitals is one which I have frequently seen advocated in your valuable journal, and with others, more directly interested in the matter than I am myself, I trusted the hints and warnings would have a salutary effect on those to whom they were indirectly addressed. It is only by the intervention of painful experience that some minds seem to be capable of being roused to a proper sense of their duties towards their fellow-men; and now that an opportunity offers for reopening the question through the untimely demise of a bright and promising young house-surgeon at one of our great hospitals, I think this the fitting occasion respectfully to urge on those who represent the ruling authority the absolute necessity of studying more closely than they have heretofore done the welfare and comfort of those who fill the important and onerous posts of resident officers in our large charities.

I will as briefly as possible lay before you some incontestable facts which stand as a lasting disgrace to one of our noblest institutions. In one of our large hospitals each resident, with the exception of the resident assistant-surgeon and physician, is accommodated with only one room, wherein he is to sleep, rest, smoke, entertain his friends, and, as so often happens, read for his higher examinations. This is the first item that requires reform. Moreover, there is absolutely and entirely no means of recreation within the hospital, and all that the hard-worked house-surgeon or physician can do during the hour or so he has to himself between the end of his labours for the day and his evening meal, is to sit in that ever-occupied room and smoke; and what is the consequence? No sooner do men come on duty as residents than their health begins to fail; they become pale and languid, and it requires but the presence of some infectious disease to lay them on a bed of sickness, from which, as in the case above quoted, they may never rise again. I myself as well as others have noticed how severely the smallest ailments affect men who have been on duty some time; tonsillitis always attacks severely, and scarlet fever, as in the case of at least four house-surgeons in my own recollection, has incapacitated men for months subsequently from occupying the posts which they have obtained with some difficulty, and which they are always anxious to fill efficiently. From nine to ten hours a day of rushing about this huge building while on minor duty, and the constant hard work from 9 A.M. to 2 A.M. while on major duty, suffice ere long to exhaust the strongest man. When he is treated to this scanty and inefficient accommodation, and is absolutely debarred from any healthful open air relaxation, he is placed at a much greater disadvantage when he encounters some dangerous infectious disease, than one in healthier surroundings. But these are not the only evils that require reform. The action of those who have framed the rules for the conduct of house-surgeons has absolutely vetoed his leaving the hospital for out-door exercise, without going through an absurd and unnecessary form of obtaining leave. He has to obtain permission from two, and give due notice to three other officials, by means of printed forms, before he can indulge in the luxury of a walk away from the hospital and its surroundings. Now, Sir, what is the unfortunate victim of this uncalled-for officiousness to do? Close attention to his work, no time for recreation, either mental or physical—living ever in the close, stuffy, germ-laden atmosphere of a London hospital—surely when disease in any shape seizes on him he is struck down with a heavier blow than he would be were he in perfect health, and now and then he becomes the victim directly, it is true, of the disease which asserted itself, but indirectly also of that wretched provision for his comfort and well-being which rendered him so easy a prey. Can you not, through the columns of your widely circulated and valuable journal, advocate the cause of the unfortunate resident? Cannot you urge on those who are responsible the necessity of providing better accommodation for him—a racquet court, a lawn tennis court, or a billiard table—to relieve him from the mental and physical strain to which his work puts him daily? Surely the school and college will gain in the esteem of the public and the profession when they evince such an interest in the welfare of those who serve them so conscientiously. The lesson those who are in authority have to learn, a lesson they have unfortunately learnt before, but have not heeded, is to be less severe and more generous to and thoughtful of those who toil day and night for the good of their fellow-men. Trusting some good may come from this appeal, and apologising for trespassing on your space so largely,

I am, Sir, yours truly,

December 15th, 1885. MEDICUS.

Dr. A. Boggs (Paris).—Full details on the subject will be found in Dr. Parkes' Manual of Practical Hygiene, book ii., chap. 2, sect. 2, "The Food of the Soldier."

HOTTENTOT PATHOLOGY: A REMARKABLE SUPERSTITION.

To the Editor of THE LANCET.

SIR,—It may be interesting to your correspondents who wrote on the above subject in your issues of June 13th and 27th, 1885, to know that the idea about the "uterus flying upwards after parturition" prevails universally among the native Singhalese of Ceylon. The midwifery practice among them is entirely in the hands of their midwives, whom I have seen tightly grasp the funis by twisting it round the index-finger to prevent the after-birth going up about the chest and obstructing the respiration.—I am, Sir, yours faithfully,

W. WIJCYESAKERE,
House-Surgeon to the Government Civil Hospital,
Dec. 4th, 1885. Galle, Ceylon.

L.R.C.P.E.—The proceedings at the meeting referred to were not declared to be secret.

D. L.—Undoubtedly the case can be, and should be, dealt with by the authorities of the College whose licence is thus disgraced.

GARROD'S "MATERIA MEDICA."

To the Editor of THE LANCET.

SIR,—In consequence of the recent publication of numerous corrections in the British Pharmacopœia, certain alterations have been found necessary in the new edition of Garrod's "Materia Medica." Will you kindly announce that a printed list of these can be obtained from the publishers, Messrs. Longmans and Co., or from myself.

I am, Sir, yours faithfully,

NESTOR TIRARD, M.D.,
(Editor of Garrod's "Materia Medica.")

Weymouth-street, W., Dec. 22nd, 1885.

Enquirer (Camp Dolan) will find information on the subject in THE LANCET of Oct. 10th last, page 680.

INCISION OF OS AND CERVIX BEFORE REDUCING THE INVERTED WOMB.

To the Editor of THE LANCET.

SIR,—In your issue of Dec. 26th, 1885, p. 1183, Dr. Arbuckle describes this operation as due to Dr. Barnes. A glance at the "Medical Digest," Section 1137: 6, will show that Dr. Pratt of Fife contributed a paper to the *Medical Times and Gazette* in 1868, in which he asserts that Wassiege of Liége is the sole originator of this most effectual plan.

I am, Sir, yours obediently,

Boundary-road, N.W., Dec. 28th, 1885. R. NEALE, M.D. Lond.

Mr. H. Raymond.—The term is not commonly employed; but, if used, it would be perfectly correct.

Digitized by Google

UNIVERSITY OF LONDON.

FROM our list of medical members of the special committee to consider Lord Justice Fry's scheme (see vol. ii., 1885, p. 1116) the name of Dr. Baines was inadvertently omitted.

Mulcted.—Possibly the Medical Defence Union, Bedford-row, might assist our correspondent.

"FÆCAL ACCUMULATION."

To the Editor of THE LANCET.

SIR,—I have read with much interest the able article in THE LANCET under the above title, by Mr. Fred. Treves, F.R.C.S., of the London Hospital, and although able to agree with the writer upon some points, yet I cannot endorse his remarks upon the secondary importance of constipation—viz., that the daily evacuation of the colon and rectum is unnecessary, or that a full colon involves (in moderate constipation) no material alteration in the contents. As to the latter, he seems to ignore the fact of organic decomposition and generation of carbonic dioxide gas, with consequent flatulence and its attendant evils, as pressure upon surrounding viscera and nerve plexus, &c. That drastic, or even mild, purgatives and the largely increasing exhibition of saline waters are evils there can be little doubt, and that to fly for the relief of any symptom to such remedies is both unscientific and baneful. But what I am most anxious to draw attention to is another aspect of the question—viz., the daily use of what I should like to term "natural food," notably bread and pastry made from wheaten flour in its entirety and more or less finely ground. I have for the past two years abandoned the use of white bread and pastry altogether, and, unless visiting at the house of a friend, never take it; the result has been a daily evacuation of the intestines, instead of constipation as formerly, and a condition of health, both of mind and body, never before experienced. This has nothing whatever to do with mental bias, to which Mr. Treves refers, but is a practical outcome resulting from improved dietetic habits alone. Again, I never suffer from thirst, and often forget to drink at dinner; and unless my attention is drawn thereto by others, I should scarcely drink at all at meal-time. A withdrawal of water from the system either by the skin or kidneys means usually thirst as a resultant; but with me, the amount of water passed with the fæces being but small may account for this phenomenon, thus forming a marked contrast to what would ensue were I to take aperients for relief of constipation. The woody fibre in the proportion found in entire wheaten flour is, in my opinion, enough, and only enough, for the healthy stimulation of peristalsis; and, moreover, the additional amount of nutriment—as bone phosphates and albuminoids—contained in the bran-cells more than compensates for any supposed physiological waste to which Mr. Treves refers. By observing such simple and pleasant rules as those to which I have alluded aperients become a "dead letter," and constipation, whether it be moderate or excessive, is avoided; and not this only, but a more perfect digestion takes place, and a perfect assimilation also, thus avoiding one of the chief causes of gastric and intestinal trouble.

I shall feel obliged if you will insert this brief reply in your next issue, trusting that the question of "natural food" may be better considered by the faculty.

I am, Sir, yours truly,

December, 1885. PATHOLOGIST.

"ITCHING OF JAUNDICE."

To the Editor of THE LANCET.

SIR,—For this distressing complaint I have used on two occasions during the past month hypodermic injections of pilocarpine in doses of one-tenth of a grain. The immediate effect is to intensify the suffering; but when diaphoresis occurs, relief is rapidly obtained, and lasts from twenty-four to thirty-six hours. It is occasionally advisable to give the patient a little brandy before injecting the pilocarpine.—Yours truly,

Dec. 28th, 1885. J. J.

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Lectures
ON THE
SURGICAL TREATMENT OF EMPYEMA.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.

By RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

GENTLEMEN,—Statistics are most misleading. Perhaps they are never more so than when they are compiled from the material which is met with at a special hospital. I must, however, present you in the first place with a tabular statement—I fear not quite a complete one—of the cases of empyema which have occurred during the year that I have been officially connected with the hospital, and of a few others that were under my care before that time. A glance at the list will show that it is a record of a very promiscuous series of cases. It was difficult to arrange them in any illustrative manner, and I have accordingly placed them in the order of age. Such a table is a good illustration of the fallacies to which the study of statistics may lead; for although the actual mortality cannot be said to be high—five out of twenty cases having died, two of which were after leaving the hospital—it will be noted that the number of perfect cures is comparatively small; and anyone who formed his opinion as to the results of the treatment of empyema from the statistics of this hospital might conclude that the treatment of the disease is far from encouraging, so many of the cases having left the hospital still wearing the tube, with the remark appended to their case, "improved"—often merely a euphemistic rendering of *in statu quo*. But if he happened to formulate his views from observations made at another institution with which I have the honour to be connected—the North-Eastern Hospital for Children—he would conclude that empyema is one of the most curable of diseases, for by referring to this other table it will be seen that amongst thirty cases there has only been one death (that of a markedly tubercular infant, who had an empyema upon the opposite side); and that very few left the hospital unhealed, while the majority were completely cured in a very few weeks, and even those whose recovery was more protracted ultimately, with one exception, healed completely.

I will not dwell upon a third class of cases which might supply material for statistical tables—namely, those which are met with in private practice, though perhaps it might be shown that similar cases to those we meet with here have a better chance of recovery under the more advantageous conditions of a good home than the undoubtedly very favourable one that we are here able to offer them. Nor will I give you a list of cases from a general hospital, though these would probably afford the most trustworthy basis for an argument; but I will shortly point out a few of the reasons for the different results obtained at these two special institutions. Some at least of these must be at once apparent, the principal ones being the difference in the age of the patients, and the fact that many of those who come here are either quite chronic cases or the subjects of more or less advanced tubercular disease. It may of course be said, and with truth, that the majority of the cases of empyema at a children's hospital have in a marked degree the appearance which we are in the habit of describing as "tubercular": that is, they are thin, with delicate features and narrow chests; they have downy skins and notably hairy foreheads, and long dark eyelashes; and not infreqently we can discover a family history of tubercular or strumous affections. But, on the other hand, they are not as a rule pulled down by chronic phthisical changes; their lungs are not, as many of those we meet with here, consolidated and inexpansible, and if actually tubercular, this is the first manifestation of the disease in an otherwise comparatively healthy body. The question of age, however, is probably the most important one. It implies, besides the difference of recuperative power so marked between children and adults, a difference in the most important factors concerned in the closing of an empyema. To begin with, the tissues of a child have apparently a greater faculty than those of an adult of absorbing not only serum but pus; and I cannot doubt that a certain number of empyemata in children are really made away with by simple absorption, without surgical interference. This is illustrated by the fact that acute suppuration of joints and large intermuscular abscesses may be satisfactorily treated in infants by means of a much smaller incision than would be considered at all adequate for an adult. That the pleura may deal with pus in this way, even in adults (though perhaps only in young adults), is illustrated by two cases which have occurred here (Nos. 7 and 10, Table II.); for it must be remembered that when an empyema is aspirated, it is generally, if not always, impossible to extract to the last drop the pus contained in the chest, as such a complete evacuation would imply the perfect adaptation to each other of all the walls of the cavity in which the pus was contained, and therefore almost necessarily the complete expansion of the lung—a result which must be very rarely met with. But the question of age tells in a more marked way after the chest has been opened by a free incision. Let us consider the manner in which a cure is effected under such circumstances. The lung, unless it has previously become adherent to the chest walls, at some points, is lying at the back of the thoracic cavity, occupying the hollow formed by the angles of the ribs, and perhaps adherent also to the structures in the middle and posterior mediastina. The process which has to take place in order that the opening may close is a bringing together of the walls of the cavity and the surface of the lung. Now it is quite impossible for the lung to be distended by any inspiratory efforts; this would be opposed to the laws of physics; and no suction power is available as long as there is a free opening into the chest, yet somehow the closure of the cavity is brought about. The only possible power by which this can be accomplished is illustrated by Figs. A and B. The whole interior of the pleura which has suppurated becomes lined, if not with actual granulations, at least with a material which, like them, in its advance to a more highly organised condition, necessarily undergoes a process of contraction; and that which occupies the angles, shown in the figures between lung and chest walls, lung and diaphragm, lung and mediastinum, and diaphragm and chest-walls, is constantly drawing these structures towards one another. Thus the chest walls fall in, causing approximation of the ribs and a lateral curvature of the spine, with its dorsal concavity, towards the affected side and slight compensatory curves, in the opposite sense, in the lumbar and cervical regions; the diaphragm comes up, the mediastinum is drawn over with an accompanying expansion of the unaffected lung, and the affected lung is also drawn out and made to expand. Now, in a child the lung is more expansible, and the chest wall is much less rigid than in the adult, and thus the possibility of the completion of this process of closure is much greater. Perhaps it may sometimes happen, after the pleura has regained its healthy condition, if the opening in the chest wall has closed, that a cavity may remain containing a small amount of serous fluid, and that the final process may be the absorption of this fluid; but this, if it ever occur, is the exception, and not the rule. In the case of an adult such as J. F. (Table II., No. 18), a time is reached when the rigid chest walls have fallen in to their uttermost possible extent, the diaphragm has risen as high as it can, and the collapsed lung, coated with its thickened pleura, has been drawn out to the furthest possible extent. Then nothing further can take place, and nothing more remains to be done, except to let the patient go home with a permanent fistulous opening, or to adopt some of the methods to be mentioned in the next lecture to render the chest walls less rigid and more collapsible.

These, then, I think, are the most important considerations in accounting for the different results at these two hospitals, and they are sufficient to justify the position that any general assertions as to the treatment of this disease must, if they are to be of any value, be founded upon a very wide experience of all classes of cases. For this reason I refrain at present from attempting to draw any such conclusions.

It may be deduced from what has been said as to the method by which an empyema closes, not only that those

TABLE I.

THIRTY CASES OF EMPYEMA TREATED AT THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

No.	Name.	Age.	Duration.	Variety.	Treatment.	Result.
1	John E.	1 year.	3 months.	Left, localised, tubercular.	Aspirated, Jan. 9th, 1883, 1 pint; Jan. 23rd, 6 oz.; Jan. 30th, 4 oz. Opened, Feb. 10th, behind; rib removed.	Death. Empyema on opposite side.
2	Mabel P.	1 4/12 ,,	1 month.	Left, general.	Aspirated, July 11th, 1884; opened, July 26th; part of 8th rib removed behind.	Cured in 6 weeks.
3	J. Joseph M.	1 10/12 ,,	3 weeks.	Right, localised.	Opened, Nov. 23rd, 1881, behind; tube out, Dec. 13th.	Cured in 5 weeks.
4	Rosie R.	2 years.	6 weeks.	Left, localised.	Opened, Aug. 1st, 1885; rib removed behind; tube out, Aug. 13th.	Cured in 4 weeks.
5	Frederick E.	2 4/12 ,,	9 weeks.	Right, general (?). Subcutaneous rupture outside and below nipple.	Aspirated, July 4th, 1885; opened through abscess, July 7th; tube removed, July 15th. Part of 7th rib removed; tube put back, Aug. 7th; finally removed, Aug. 15th.	Cured in 9 weeks.
6	George R. G.	2 5/12 ,,	14 days.	Left, general (?).	Aspirated, Aug. 14th, 1883; opened, rib removed behind, Aug. 17th; tube removed, Sept. 1st.	Cured in 5 weeks.
7	Elizabeth L.	2 6/12 ,,	8 months.	Left, localised.	Aspirated, Feb. 9th, 1885; opened, rib removed behind, Feb. 28th; tube replaced twice; counter-opening, June 17th.	Left in September, not quite healed.
8	George M.	3 ,,	2 months.	Left.	Aspirated, Aug. 20th, 1883; opened, Aug. 24th; rib removed behind; tube removed, Oct. 2nd.	Practically cured in 8 weeks.
9	Florence E.	3 ,,	(?)	Left, general.	Aspiration failed; opened, Nov. 14th, 1883; rib removed behind.	Cured in 10 weeks.
10	James D.	3 ,,	6 weeks.	Right, general (?).	Aspirated, Nov. 25th, 1884, 5 oz., very thick pus.	Cured by one aspiration.
11	Frederick D.	3 ,,	5 months.	Left, general.	Aspirated, Dec. 3rd, 1883, 2 oz.; Dec. 4th, 1 oz. Opened, rib removed behind, Dec. 7th.	Practically cured in 7 weeks.
12	Florence P.	3 4/12 ,,	3 weeks.	Right, localised.	Aspirated, May 12th, 1885, 4 oz.	Cured by one aspiration.
13	Florence S.	4 ,,	(?)	Left, general (?).	Aspirated, Oct. 31st, 1884, 29 oz., sweet; Dec. 8th, expectorated, 2 oz., fetid. Opened, Jan. 25th, 1885; rib removed behind; pus fetid.	Cured in 8 weeks.
14	Helena B.	4 ,,	3 weeks.	Right, localised.	Aspirated, April 28th, 1884, 1 syringeful.	Cured by one aspiration.
15	John W.	4 ,,	2 weeks.	Right, general.	Aspirated, Aug. 9th, 1885. Opened, Aug. 5th; rib removed behind. Tube removed, Aug. 26th; put back, Aug. 31st; finally removed, Sept. 16th.	Practically cured in 5 weeks. Tube removed too soon.
16	Ada L. H.	5 ,,	(?)	Left, general (?).	Aspirated, April 7th, 1882, 10 oz.; April 9th, 7 oz.; opened, April 10th; tube reinserted, Sept. 9th.	Practically cured in 6 months.
17	Sydney N.	5 ,,	(?)	Left, general (?).	Aspirated July 21th, 1883, 4 oz.; July 26th, 11 oz. Opened, Aug. 12th; rib removed behind; tube left out, Aug. 29th.	Cured in 4 weeks.
18	Daisy M. H.	5 ,,	1 month.	Left, general.	Expectorated two months after commencement of illness.	Cured.
19	Eliza C.	5 ,,	5 months.	Right, general (?), opening in 7th space.	Part of 7th rib removed, and tube put in, Feb. 17th, 1883; left out, March 27th.	Cured in 6 weeks.
20	Florence C.	5 6/12 ,,	2 weeks.	Left, general.	Aspirated, April 3rd; opened, 10th; rib removed behind.	Cured in 8 weeks.
21	Henry E.	5 6/12 ,,	10 days.	Left, general.	Aspirated, June 16th, 1882, 26 oz.; opened July 1st, 7th interspace; July 7th, rib removed; tube left out, Sept. 2nd.	Cured in 14 weeks.
22	Joseph W.	5 6/12 ,,	4 days (?).	Left, general; lung solid.	Aspirated, May 12th, 1884; opened, 27th; rib removed; July 13th, second opening further back.	General health good, but sinus remains, Sept., 1885.
23	Alfred J.	6 ,,	5 weeks.	Left, general.	Aspirated, Jan. 29th, 1885; subcutaneous rupture near nipple, Feb. 7th; opened through abscess, 6th interspace; no rib.	Cured in 8 weeks. Trouble with tube.
24	Gertrude S.	6 ,,	4 months.	Left, general.	Aspirated, Jan. 10th, 1885; opened, rib removed behind, 26th.	Small cavity remaining for 3 months.
25	Mary C.	6 ,,	4 months.	Left, localised.	Aspirated, Nov. 18th, 1884.	Cured by one aspiration.
26	William D.	6 ,,	6 weeks.	Right, localised.	Aspirated, July 7th, 1885; opened, rib removed behind, 17th; tube removed, 29th.	Cured in 3 weeks.
27	Lydia S.	7 ,,	3 weeks.	Right, general (?).	Aspirated, Aug. 24th, 1883; 27th, 4 oz.; Sept. 1st, 9 oz. Opened, rib removed behind, Sept. 8th; tube left out, 20th.	Cured in 3 weeks.
28	Ada B.	8 ,,	(?)	Right, general, putrid.	Aspirated, April 10th, 1882; opened, 21st, 7th interspace; no rib.	Cured in 4 weeks.
29	Cornelius S.	9 ,,	9 days.	Right, general.	Aspirated, May 2nd, 1882, 3 oz.; 5th, 22 oz.; 19th, 20 oz. Opened, 23rd; no rib. Tube removed, July 19th.	Cured in 9 weeks.
30	Maria C.	10 ,,	12 months.	Left, general (?). Subcutaneous rupture near nipple.	Opened through abscess in 7th interspace; no rib, March 31st, 1883. Pus vomited during operation.	Practically healed in 7 weeks.

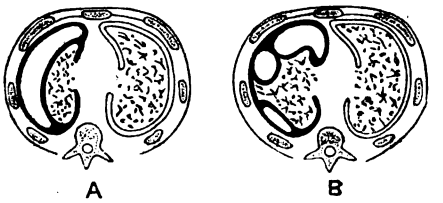
TABLE II.

TWENTY CASES OF EMPYEMA TREATED AT THE BROMPTON HOSPITAL.

No.	Name.	Age.	Duration.	Variety.	Treatment.	Result.
1	Alice C.	5½ years.	5 months.	Right, stinking, localised.	Sept. 6th, 1883, piece of 6th rib outside nipple removed; healed. Reopened, Nov. 30th.	Never completely healed. Died afterwards of bronchitis. (A very delicate child).
2	Charles W.	6½ ,,	3 months.	Left, general.	June 18th, 1885, incision.	Healed in 3 months.
3	Elizabeth A. M.	7 ,,	1 month.	Left, general.	Aug. 22nd, 1884, part of 7th rib removed behind.	Healed on Sept. 23rd (under 5 weeks).
4	James H.	10 ,,	5 years.	Left, general. Two sinuses, one 2nd interspace near sternum, one near nipple. Much contraction.	Dec., 1883, openings dilated; Feb., 1884, parts of 5th, 6th, 7th, and 8th ribs removed; July 11th, several other pieces of rib removed; Nov. 20th, opening into 1st intercostal space.	Much improved. All closed but a minute cavity, into which a straight celluloid tube, 2½ in. long., was inserted.
5	William B.	11 ,,	7 months (?) or more.	Right, localised.	July 2nd, 1885, incision; closed in six weeks; then reopened, Sept. 28th,	Still discharging.
6	Emily C.	16 ,,	6 months.	Left, localised. Rupture of 2nd interspace; lung adherent in front.	Dec. 11th, 1884, part of 9th rib removed behind; tube left out, Feb. 6th, 1885.	Healed in about 8 weeks. ? Tubercular.
7	Giuseppe D.	17 ,,	A few days.	Right, large effusion.	June 26th, aspirated, 52 oz.; July 25th, aspirated, 26 oz.	Cured.
8	William S.	20 ,,	6 months.	Left, general.	June 18th, 1885, incision; part of 6th rib removed.	Commencing phthisis. Still discharging.
9	Louise G.	20 ,,	9 months.	Left, general. Subcutaneous rupture of 7th interspace.	Sept. 17th, 1883, abscess opened; piece of rib removed in mid-axillary line.	Healed on Dec. 4th. (About 11 weeks.) ? Tubercular.
10	W. James S.	21 ,,	6 months (?)	Right, large effusion.	Feb. 4th, 1885, aspirated, 90 oz.	Cured. Effusion had just become purulent.
11	Edward J.	22 ,,	4 months.	Right, general (?) Rupture of 5th interspace.	Aug. 7th, 1884, opening enlarged; part of 5th rib removed.	Healed, 8th Oct.; well, Oct., 1885.
12	Francis S.	23 ,,	2 years.	Right, localised. Burst into bronchus.	Sept. 6th, 1883, opened; rib removed in axilla; healed. Nov. 15th; refilled, and opened again, Dec. 7th; 3 in. of two ribs removed, Jan. 28th, 1884.	Left, with tube. Healed after a second opening by Mr. Cross, of Clifton.
13	Frederick G.	27 ,,	10 months.	Right, general.	Nov. 23rd, 1883, opened; second opening, Feb. 7th, 1884, 10th interspace; never drained properly.	Death. Tubercular.
14	James L.	(?)	6 months.	Left, general.	Nov. 23rd, 1883, incision, 8th interspace behind; condition doubtful; lung incised.	Death from abscess of brain. ? Tubercular.
15	Alfred M.	31 ,,	6 months.	Left localised. Subcutaneous rupture of 2nd interspace, and into bronchus.	July 31st, 1884, abscess incised, opening in 8th interspace behind (no rib); healed, Aug.; reopened after several months.	Practically healed on Nov., 1885.
16	Harriet B.	36 ,,	1 year.	Right, general.	Oct. 28th, 1884, aspirated, serum; Nov. 4th, opened (no rib); stinking pus.	Death. Tubercular ulceration of intestines. Peritonitis.
17	Alfred D.	36 ,,	Old.	Left, localised (?)	A long piece of one rib removed.	Under treatment.
18	Joseph F.	37 ,,	14 weeks.	Right, general.	Aug. 16th, 1884, aspirated, serum; Aug. 29th, opened behind (no rib); stinking pus.	Very gouty. Left, with a large cavity.
19	Robert C.	45 ,,	3 years (?)	Right, general. Spontaneous rupture of 4th interspace outside nipple.	Sept. 22nd, 1883, opening enlarged; second opening in 7th interspace.	Improved. Left, wearing a tube.
20	Harriet A.	49 ,,	1 year.	Right, localised. Much pus expectorated.	Aug. 20th, 1884, incision, low axilla (no rib).	Perhaps a pulmonary abscess. Left, with tube, much improved. Died, March, 1885.

Summary of Table I.



Number of cases, 20. Average age, 4½ years. Males, 14; females, 16. Right side, 11; left, 19. Localised, 8 (right, 4; left, 4). Healed after opening, 18. Average time, 6 weeks. Cured by an aspiration, 4 (right, 3; left, 1; all localised). Left with a sinus, 4. Died, 1. Spontaneous rupture, 4 (1 in 7th right interspace; 1 in 5th left interspace; 1 in 5th or 6th right interspace; 1 in 5th or 6th left interspace).

Summary of Table II.

Number of cases, 20. Average age, 23½ years. Males, 14; females, 6. Right side, 11; left, 9. Localised, 7 (right, 4; left, 3). Healed, 6. Average time, 3 weeks (1 reopened afterwards). Cured by aspiration, 2 (right, general). Left with a sinus, 9 (1 healed after leaving). Died, 3 in hospital, 2 subsequently. Spontaneous rupture, 6 (5th right interspace; 2nd left interspace; 7th left interspace; 2nd left interspace; 4th right interspace; 2nd [illegible] left interspace).

Digitized by Google

who have rigid chest walls and a dense inexpansible lung are in a very unfavourable condition, but also that those in whom the empyema is localised, or in whom the lung has contracted adhesions at one or more points to the chest walls, have a better chance of recovery than those in whom the empyema is general. For here there is not only a smaller cavity to fill up, but there are more angles in which the contracting power of the lowly organised material which has been referred to can exert itself. (See diagrams.) Thus in

Diagrammatic section of cases of empyema, to illustrate the manner in which the contraction of the granulation lining the pleura (represented by the thick black line in both figures) draws the lung and chest wall together.—A, General empyema, with lung collapsed against mediastinum. B, A case in which the lung is adherent to the parietal pleura at several points.

the case of E. C. (Table II., No. 6), the lung was adherent in front except at the apex, so that when the finger was introduced through the spontaneous opening in the second space in front, it passed over the apex into the upper part of a cavity behind the lung. Into the extreme lower part of this a drainage-tube was inserted by making a second opening behind, and the patient recovered completely in two months. So in the case of A. M. (Table II., Case 15), where an almost precisely similar condition presented itself, and a corresponding rapid healing was effected, though his condition on admission was so bad as to appear almost desperate. This case raises a very interesting question, to which I wish to direct your attention, though I cannot supply a very definite answer to it. He left the hospital cured, and returned to work, as was supposed, with his pleural cavity completely obliterated. He continued at his work in a good state of health for several months, and then returned with both the upper and lower openings re-established, necessitating the dilatation of the posterior one and the reintroduction of a tube, which he is still wearing. It is not a very unusual occurrence for an empyema to close completely, or at least for the outer opening to close, and for a reaccumulation to occur almost at once, no doubt because the deep part has never become solidified; but I do not think it is very common for the patient to remain in good health for many months, and then for a fresh discharge of pus to declare itself. I have under my care now a gentleman whom I first saw in March, 1884. He was then much reduced by an empyema, following an attack of pneumonia, from which he had been suffering for a considerable time, which he was expectorating and which had ruptured through about the seventh space in the left axilla, forming a large collection under the skin. Though his case appeared most unpromising, he made a most excellent recovery in two months. A second accumulation occurred very soon—i.e., about a month after,—which was opened at the same place and rapidly closed; he then remained in robust health for five months, returning to his business and feeling perfectly well, when after exposure to cold the accumulation of matter again occurred. Again it closed rapidly, and again he was perfectly well for another five months, when, without any warning, the process repeated itself, and he is now performing one of his rapid feats of recovery.[1] It is interesting to speculate as to the state of the pleura in these two patients during their periods of apparently absolutely good health. The question arises whether in these cases there is left a small cavity containing perhaps serum, or possibly even pus, in which at last the effect of *tension* is felt in the production of acute inflammation; or whether it is this lowly organised material which, under the effect of some unusual stimulation, accompanied perhaps by an impaired state of the general health, becomes inflamed and suppurates. The latter suggestion seems the more probable; it may be illustrated by what occurs in the neighbourhood of the cæcum of a patient who is the subject of repeated attacks of perityphlitis; or by the condition of one who has a chronic stricture or long-standing enlargement of the prostate, in whom an apparently trivial irritation may light up acute inflammation and suppuration in the products of the chronic interstitial inflammation that has taken place in the kidney. The observations of any who may have the chance of making post-mortem examinations on cases of cured empyemata would be of great value in clearing up this question.

(To be concluded.)

1 The opening has now been completely closed for two months.

ABSTRACTS OF THE

Brown Lectures,

DELIVERED AT THE

UNIVERSITY OF LONDON,

By VICTOR HORSLEY, M.B., B.S., F.R.C.S.,

PROFESSOR SUPERINTENDENT OF THE BROWN INSTITUTE, ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURES IV. & V.

CANINE CHOREA.

CANINE CHOREA frequently follows an acutely infective specific malady—distemper. A parallel was drawn between the nervous phenomena that followed diphtheria and canine chorea. In both these cases the original diseases—diphtheria and distemper—were frequently of slight intensity. It was difficult to ascertain with certainty the interval of time that elapses between the first stage of the distemper and the first spasms of canine chorea. The period was, however, assumed to be from two to three weeks. Occasional uncertainty in the movement of a limb was sometimes the first symptom observed. When the animal is at rest, the limb would be found to twitch very regularly and comparatively slowly. As soon, however, as the animal made a movement, when we must suppose that some interference ensued as the result of excitation of the cerebral cortex, the tremors or twitchings were suppressed. As the case progresses the twitchings become more and more marked. A graphic record of the movements shows how they become superadded to the voluntary curve of the muscles of the limb investigated. The twitchings may affect opposite limbs, or all four limbs equally, or "crossed opposite" limbs. The final stage of the disease is one of paralysis that spreads upwards to the vital centres in the medulla oblongata. Mr. Horsley could not concur in the statement of Legros and Onimus that the sensory functions are affected. They formed their conclusion as the result of removal of the posterior cornua and columns; for they found that the movements became markedly weaker in the limbs corresponding to the part of the cord removed. This simply meant that the functions of the anterior cornua were depressed by the shock (if nothing more) of the removal of the posterior cornua. It was difficult to test the state of the reflex actions; but, so far as could be ascertained, there was no change until towards the end of the disease. This circumstance was regarded as another proof that the posterior cornua were not the seat of the disease. In a young mongrel terrier the left fore-limb was in a remarkable state of contraction; there were flexion at the elbow and adduction of the limb to the chest. The contracture could be overcome by extending the elbow with considerable force; but this effort gave the animal no pain, and thus differed from the "breaking-down" of contractions dependent on cortical irritation. Mr. Horsley was of opinion that the discharges that maintained the contracture probably emanated from the corpuscles of the anterior cornua, and examination proved these corpuscles to be diseased. Necropsies showed that the emaciation observed in the dogs suffering from canine chorea was due principally to loss of fat. Anæmia and atrophy of muscle were always present. The other general conditions—such as fall of blood-pressure, loss of appetite, &c.—advanced *pari passu* with the exhaustion of the whole system. Speaking of the differences of human and canine chorea, Mr. Horsley said that graphic records of the muscular movements showed the differences very plainly. In human

Digitized by Google

chorea, a large wave was the distinctive feature, and this was followed by smaller waves, but there was no regularity in the recurrence of the large waves; in canine "chorea" there were perfectly regular waves repeated at definite intervals. Although human chorea might be the result of defective nutrition, possibly brought about by capillary embolism, as Dr. Angel Money's experiments tended to show, still the constancy of the movements of canine chorea made it impossible that the spinal cord could to the same degree be the seat of the lesion in human chorea. Regularity and constancy of action were the characteristics of a lower centre. The movements of canine chorea were compared with those of disseminated sclerosis, paralysis agitans, and tremors of (?) incipient sclerosis occurring in one limb in young men. It was true that the movements in canine chorea were diminished when a volitional movement was made, and that those of disseminated sclerosis were developed by volitional movements, but there was not so much difference between these conditions if we carefully inquired into them. In disseminated sclerosis, if the movement were a powerful one, such as grasping an object, the tremors did not appear until the grasp was relaxing, and the same thing could be observed in canine chorea. Both in the human diseases and in a bad case of canine chorea there were two distinct kinds of twitchings: one a constant rhythmical series of clonic spasms coming on first after a voluntary effort when the limb was more or less at rest, and the other an incoördinated series of twitchings which disturb the direction and force of the volitional act itself. Canine chorea afforded an illustration of the general proposition adverted to in the second lecture, that the fundamental rate of nervous discharges from the spinal cord was from eight to ten per second. Stimulation of the uncut nerve going to the choreic muscles in no way alters the occurrence of the spontaneous spasms, for they may still be seen on the top of the curves of tetanus due to the artificial stimulation. This circumstance, and the fact that the movements do not continue after section of the nerve, even though a gentle stimulus be used to keep up the muscular tonus, prove that the disease is situated in the central parts of the nervous system. The rate of the spasm and the absence of facial spasms go to prove the dependence of the spasms on disease of the spinal cord. Section of the spinal cord above the seat of the spasms does not hinder their occurrence, or only for a short time. Stimulation to fatigue of the cerebral cortex increases the strength of the choreic movements, and the same result was observed after stimulation of the spinal cord. In a dog, with movements only in the right fore-limb and left hind-limb, stimulation of the cord caused the appearance of movements in the left fore-limb. This was no doubt due to exhaustion and etherisation; the unaffected parts were on the point of becoming choreic, and only required some lowering of their nutrition to induce the spasms.

Stimulation of the cerebral cortex produces more or less tetanus of the affected muscles proportional to the degree of disease. In some instances the lever in writing the line of tetanus scarcely rose above the abscissa; the cortex soon became exhausted, and then apparently acted merely as a conductor. Stimulation of the spinal cord has greater or less influence, also, according to the progress of the disease.

Influence of cortex.—If ether be administered so as to abolish sensation, but not to prevent the choreic movements, stimulation of the cortex will be found invariably to double the rate of the choreic rhythm. The degree of tetanus due to cortical stimulation varied directly with the stage of the disease. As a rule, tetanus set in slowly after a long latent period, and then after a short interval began to fall before stimulation ceased; it was also sometimes prolonged one or two seconds after the cessation of stimulation. The chorea could be frequently seen to return at its original rate on the curve of tetanus before even the stimulation was stopped. The choreic waves are seen to be doubled in rate on the first part of the curve of tetanus, but this doubling soon disappears as the tetanus falls and the original choreic rate reappears, continuing, of course, after cortical stimulation has ceased. The second remarkable effect on the twitchings produced by cortical stimulation when it did not cause tetanus is an increase in the amplitude of the twitchings; this increase may be four- or eight-fold. Prolonged stimulation of the centre did not cause diminution of the rate, but a slight gradual fall of energy as the centre became exhausted; that is to say, the doubling of the rate was not prevented, but the amplitude was diminished considerably below the original level.

Cortical stimulation has a twofold effect, increasing the *frequency* as well as the *amplitude* of the muscular spasms. Probably increase in the amplitude is dependent on the energy discharged from the cerebral cortex, and this being so, it was easy to understand how the effect should soon pass away, for the energy in the irritated cortical centre would soon be dissipated. Stimulation of the corona radiata in the majority of instances exerted no influence on the rate of the chorea. This observation is not conclusive, for in one instance a doubling and in another no alteration was noticed. Stimulation of the cervical region of the spinal cord caused doubling of the rate of the spasms, but diminished by one-half the amplitude of the contractions. So that it would seem impossible at the same time both to increase the frequency and the amount of nervous discharges. Much stress was laid on the conclusion that the amount of energy discharged cannot be increased when the same strength of current is employed. This observation served as a further illustration of the law that motor nerve centres discharge their energy about eight times per second.

Mr. Horsley has frequently observed that, whether the nerve corpuscles of the cord be fatigued by repeated stimulation or depressed by asphyxia or etherisation, the recovery of the former rate of nerve discharge (as determined by muscular twitchings) is not attained by a steady increase in rate and amplitude. The return to normal commences with a pause after the cessation of stimulation, that lasts a varying length of time, but not longer than two seconds; then comes a small contraction, next a shorter pause, then a series of large choreic twitches, about one every second; after these have lasted a few seconds, the chorea somewhat abruptly assumes the normal rate and the contractions their average strength. The return of energisation was not a direct return to the natural rhythm, but a kind of storage of energy even beyond the level at which, were the cell not fatigued, discharge would occur. Poisoning as in asphyxia appeared to double the rate of the chorea, but diminished the amplitude by one-half of the contractions. Powerful stimulation of an afferent nerve, like powerful stimulation of the spinal cord, causes such tetanus that the twitchings are lost in the general fusion of contractions.

Investigating the general question of the total discharge of energy by the spinal cord, by which is meant the fused or summated discharges that produce tetanus of the muscle, Mr. Horsley pointed out that the commencement of the tetanic curve was very frequently a sharp and extensive spasmodic contraction, succeeded by the rest of the tetanic contractions of varying height. With a weak current the tetanic wave was found to fall very rapidly towards the abscissa; with stronger currents this fall was prevented, but the initial spasm was almost always the highest point in the curve. So soon as the stimulus becomes adequate, the tetanus is perfect, the fall as sharp as the rise, so as to imitate the characteristic curve from the normal spinal cord.

Studying the shape of the curves caused by the choreic twitchings, Mr. Horsley concludes that the normal mode of action of the nerve centres is a small discharge followed by a more powerful one; so that the curve presents a notch in its upward stroke. Theoretically, this is what we should have expected, for an automatic mechanism usually gives a minimal discharge in response to ordinary needs, and produces a more powerful discharge as the result of later stimulation. Repeated stimulation was found to exaggerate the normal mode of action just referred to. Another effect of continuous stimulation is to equalise the rhythm and amplitude of the chorea in a remarkable manner. Asphyxia first diminishes the amplitude of the contractions, and finally abolishes them. On the restoration of respiration the chorea returns, and is observed to be more equable as the result of the previous total arrest. The effect of etherisation is similar.

Professor Wood had shown that stimulation of the sciatic nerve lessens the size of the contractions. Mr. Horsley confirms this statement, and supplements it by the observation that, whilst the amplitude of the twitchings is diminished by one-half, the rate of the chorea is doubled; thus further illustrating the principle, already mentioned, that there appears to be a very definite law controlling the influence of external circumstances upon the pathological discharges from the diseased nervous centres.

Legros and Onimus have shown that a descending current diminishes the movements in canine chorea, and an ascending one increases both their rate and amplitude. It appears to Mr. Horsley that it is more a question of the degree of effect

Digitized by Google

produced than of the kind of difference brought about by the varying position of the anode and cathode, for in both instances the rhythm was increased in rate.

Coming to the morbid histology of the disease, the lecturer referred to the lesions found by Gowers, Sankey, and H. C. Wood. His own preparations agree with those of the last-named observer, and he adduced reasons for believing that the changes observed should be regarded as of the nature of disseminated sclerosis.

INJURIOUS SCHOOLING AND ITS REMEDY.

By OCTAVIUS STURGES, M.D.,

PHYSICIAN TO THE WESTMINSTER HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN.

JUST twelve months ago, as an appropriate exercise for the season, I invited attention through the columns of THE LANCET to certain events and circumstances of school life which, during the year that was then closing, had within my own experience given origin to St. Vitus's dance. The case of a child now in the Children's Hospital brings the subject once more to my mind. Like those which I related last year, it serves to illustrate the occasional hardship and even cruelty of school teaching. It would not be true, however, to represent cases of this precise pattern as common. Out of nineteen examples of chorea which fell under my care during the present year at Great Ormond-street, some three or four may be in part attributable to schooling, but only this one belongs to the category I have now in mind. The strain of mental application (especially when the learners are underfed), the excitement of competition, the fear or the grief of punishment—these are almost necessary incidents of school life, and from time to time they will prove injurious by exciting chorea; yet if in such case the earliest symptoms of the malady are recognised and rightly interpreted, that is as much as can be expected. The child is removed from school, obtains a welcome rest at home or hospital, and will presently return to work the better in health and in flesh for the holiday. But the chorea I am now thinking of belongs to another class, a class which, as I believe, is happily decreasing so far as London is concerned. It has its origin in what may fitly be called "injurious schooling." It is injurious in the sense of being, as Johnson defines injury, "hurt without justice," or, as the children themselves would say, it is "such a shame."

So far as the London School Board is concerned, I thankfully acknowledge the active interest which its late chairman, Mr. Buxton, has shown in this matter. There is reason to hope that, at the Board schools at least, precautions are now taken to ensure the early recognition of St. Vitus's dance in children, and this without any parade of medical inspection or supervision. That it is not so everywhere let the following example bear witness.

The child in question is at this moment in the Hospital for Sick Children, but was lately at a national school of a well-known and wealthy parish of the West-end. She is the subject of rather severe general chorea, and is a pale, thin girl of eleven, cheerful and intelligent, and by no means disposed to dwell on her past woes. The account given of her (which is borne out by the child's own story) is to the effect that before chorea began she was observed to be restless at night, crying out in her sleep, or sitting up and rambling about her lessons. She was always eager to be at her books, and would bring home school-work to be prepared overnight. Owing, however, to the pressure of domestic matters the lessons were often left undone, and as a consequence the girl was "kept in" and otherwise punished. For some time the strange movements of the child had been noticed at home, but nothing was thought of them, and no change was made in the routine of her life. It was ascertained (and here is one point of the story) that there had been no intentional unkindness either at school or at home. The child was anxious to learn, but too little allowance was made for her scanty opportunities of mental culture, and she thus fell into undeserved disgrace. "Do they cane at your school?" I ventured to ask, when we had become sufficiently acquainted. "Please, sir, they slap us." "But if you learnt your evening lessons you wouldn't be slapped?" "Please, sir, I have to run mother's errands." "Do you tell them so at the school?" "Yes; and teacher says I ought to get up early in the morning." "And why not? What time *do* you get up?" (severely, the season being the Vigil of St. Thomas) "At half-past six, please, sir; but I have to help mother cleaning out the place."

It was strictly true. The mother is in charge of solicitors' offices; but she is not equal to much, having some chronic illness, so that sometimes all the morning cleaning falls to the child. The father is out of work and laid up in hospital. It is a cheerless picture enough. Up at half-past six on these winter mornings "cleaning out the place for mother"; then to school, to be slapped and "kept in" for no real fault; next, an evening of errand-running in the dark streets; and finally, after joining in such pleasures of the table as fall to the lot of labouring people out of work, back once more to the dismal dreams and anticipation of new punishment in the morning. And all the while her disease growing, and with it the feeling of daily increasing inability to meet the demands made upon her. And such-like is the life of many a poor child, notwithstanding that, with the exercise of a little intelligent observation, it is all preventable. I say without hesitation, and after many years' experience, with unusual opportunities for studying this particular nervous affection of poor London children, that it is very rarely indeed that the malady is recognised at the beginning. The rule is that for weeks or for months what is really disease is taken for carelessness or perversity, and a condition which needs for its cure the utmost tenderness and allowance is thus aggravated by repeated punishment.

And where is the remedy? School teachers and people who take benevolent interest in school work often ask in bewilderment, "What *is* chorea? How am I to know it? What should I look for?" It is one of the most remarkable instances, I think, of the extreme diffidence which is prevalent in regard to medical facts that children are often brought to us wriggling and grimacing in a way that is sometimes grotesque and sometimes pitiful, while the parents blankly inquire, "What is the matter? What ails the child?" I believe that this would no longer be the case if we were to abolish the term "chorea" altogether, and adopt some simpler name. There is little enough of sense in the word; all sorts of foolish superstition cluster round it; and although the term "St. Vitus's dance," which I would substitute, is so far in much the same plight, yet this latter expression has the great advantage that everyone knows, in a sort of way, what it means. It occurs in our common talk and in general literature, and in such reference as implies that there is a popular knowledge of its main features. Chorea, on the contrary, is a word never used save by doctors and pedants.

As an illustration of what might be hoped for by this change of name, let me take the case of a kindred disease—hysteria. Everybody knows (pretty much as well, that is to say, as we do ourselves) what hysteria is. We meet with it in speeches and leading articles in such apt use as to make it plain not only that there is a wide knowledge of its common modes, but even that its pathology is well understood by these speakers and writers—better, it may be, than by some specialists. And observe that this just appreciation of the nature of hysteria supplies the proper direction for its treatment. Every efficient governess and all wise mothers, gentle or simple, are on the look out for the earliest symptoms of emotional outbreak in growing-up girls. When the laughter is too loud or the game too boisterous, it is dexterously repressed before self-control is altogether lost. There is an accurate and a widespread knowledge of the nature and incentives of hysteria, and it is utilised, and transmitted from one generation to another in every well-ordered family. Habitually, mothers prove most efficient in the correction of hysteria; habitually, they help to maintain and to aggravate chorea.

Why should it not be the same with over-movement as with over-emotion? One chief reason is, I am persuaded, that we make a mystery of a very common infirmity by calling it by a strange name. The factors of chorea (or let me say, to avoid controversy at this season of the year, *some* factors of chorea) are not less plain than the factors of hysteria. No one whose privilege it is just now to be living with children home for the holidays needs to be told that restlessness and love of movement are characteristic of that time of life. It is superfluously obvious. And there needs but a slight enlargement of that observation to perceive that mental strain and school worry, no less than the joys of home and freedom, will sometimes provoke a similar restlessness, which is even less within control, a condition rendering the limbs

Digitized by Google

for the while disobedient as well as restless, and under the influence of which the higher muscular acts—walking, writing, handling, speaking—become awkward, difficult, and uncertain. Here is an affection which is all one with the so-called "St. Vitus's dance" of the vulgar, the so-called "chorea" of the learned. And, looking at it from this point of view, we obtain, just as in the case of hysteria, not merely a picture of what it is like, but a suggestion as to its management.

But in spite of the pleadings of common sense, there is small hope of change. Not in chorea alone, but in other diseases as well, there is the common speech on the one side and our technical "nomenclature of disease" on the other, and as yet they show no tendency to come together or to hold parley. The inconvenience and inaccuracy of the word *typhoid* have often been pointed out, yet no non-professional person will speak of "enteric fever" or even comprehend what it means. The identity of scarlet fever and scarlatina we are for ever insisting upon, yet, in spite of all protest and to their own danger, the people persist in maintaining a distinction between the two. And similarly, it is to be feared, we shall still cherish our own professional chorea and marvel at the blindness of the community in respect of it; the people will still speak of St. Vitus's dance, associating it less with their own nurseries than with burlesque descriptions in books or the miracles and fanaticism of the Middle Ages. Yet, surely, in no department of medicine is this want of touch and sympathy more mischievous than in the functional nervous disorders of the young. What is needed for the alleviation, and still more for the diminution, of these common diseases of civilisation, singularly bare as they are of drug remedy, is first an intelligent understanding among the people of their real source and nature, and next the co-operation of parent or teacher on the one hand and medical man on the other with a view to their prevention or cure. But no such understanding or co-operation is possible so long as this pernicious barrier between ourselves and the community is allowed to exist. It was set up ages ago to shelter mystery and pretence, and whether from the one side or the other, be he layman or doctor, he does a good and a seasonable work who will help to pull it down.

Christmas Eve, 1885.

A SUCCESSFUL CASE OF

GASTROSTOMY FOR THE REMOVAL OF A LARGE MASS OF HAIR FROM THE STOMACH.

BY J. KNOWSLEY THORNTON, M.B., C.M.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

I HAVE waited to publish the full details of this very remarkable case until sufficient time has elapsed for any after-troubles to declare themselves; none have appeared, and the patient has enjoyed good health since the operation, and still continues to do so. In reply to a letter of inquiry, she writes: "I have no discomforts that can be attributed to the operation."

Early in 1884, C. H. J——, aged eighteen, single, was sent to me by my friend Mr. Symonds, of Oxford, for an opinion as to an abdominal tumour from which she had for some time suffered. She had already been seen by several other medical men, and very various views had been expressed as to the nature of the tumour, perhaps the most common one being that it was malignant. After in vain attempting to get any satisfactory history from either the patient or her mother, I made a very careful examination, and came to the conclusion that it was an accumulation in the colon. I therefore advised frequent doses of castor oil and the use of very large enemata. This treatment was thoroughly tried by Mr. Symonds, with the result of giving her much pain and pulling her down a good deal, but without reducing the swelling. She therefore came to see me again, and brought with her a small concretion of hair and faecal matter which she had passed while under the above treatment. A [illegible] confirmed my original opinion, and she mentioned to me that for some years she had been in the habit of eating the combings of her hair and her sewing-[illegible] to [illegible] her tongue." The question now arose, Is this mass in the stomach or transverse colon? She had suffered to some extent from indigestion, but there had been no very marked sickness or pain, and, moreover, there was the small concretion of faeces and hair. I concluded that the mass was in the colon, and advised another prolonged attack upon it with castor oil and enemata, promising, if they failed, to take her into the Samaritan Hospital and perform abdominal section. I thought it was possible, if the mass were in the colon, that after opening the abdomen it might be gradually forced along into the rectum and extracted; at the same time I was quite prepared to open either the stomach or colon if necessary.

The treatment failing to produce any result, and the patient being much weakened by the purging and enemata, her friends earnestly begged for operation, and she was admitted under my care on May 2nd, 1884. A fresh examination revealed no change in the size or position of the mass, and accordingly on May 6th, after the administration of methylene by Mr. Malcolm, I proceeded, with the assistance of Mr. Meredith, and in the presence of Mr. Symonds, Dr. John Homans of Boston, U.S., and many others, to perform the following operation:—Parietes incised in the middle line, the incision beginning two inches above the umbilicus and passing on its left to one inch below it. Stomach exposed, greatly distended by solid mass, which was evidently moulded to the shape of the viscus. Some omentum adherent to the surface of the stomach and to the parietes separated and ligatured. Incision extended two inches further below the umbilicus. Space between distended stomach and parietes carefully packed all round with carbolised sponges. Anterior surface of stomach grasped and a large fold of the great curvature brought out between the lips of the abdominal incision. Another layer of sponges packed over the raw edges of the wound round this fold. The fold transfixed and incised by a transverse incision five inches long, care being taken to avoid vessels as far as possible; a few spouted, but were easily controlled by pressure forceps. The mass of hair was at once seen, filling and distending the stomach, and was extracted by a vulsellum with a slight turning movement. The mucus was carefully wiped away all round, as the mass came out, with carbolised sponges, and the cavity of the stomach was at once thoroughly cleansed with them. A large carbolised sponge was then laid in the stomach to keep the edges of the wound in position for suture and prevent accumulation of blood in the organ. Fifteen sutures of fine carbolised silk were then introduced through all the coats, the needle being slanted through the wall so as to come out just at the inner edge of the mucous membrane, which was much inclined to curl. These interrupted sutures were passed so as to control the cut vessels, and no ligatures were used. Another row of similar sutures was then passed between each of the deep sutures, but only through the peritoneum. The deep sutures entered the peritoneal coat about a quarter of an inch from the edge of the incision, and were a third of an inch apart; the superficial sutures were entered at about the same distance from the edge, and ran along just under the peritoneum. When these were all in place the sponge was removed from the stomach, and they were tied, the deep first and then the superficial. These two rows caused some inversion of the peritoneum, and the two outer and upper peritoneal edges of the depression thus formed were brought together by a continuous suture of very fine carbolised silk. There had been no escape of blood or other material into the peritoneum, and no exposure of its contents to chill from the spray. The closed wound measured exactly three inches. The sponges used for the mucus and for the interior of the stomach were kept quite separate from those used for the peritoneum. During the suture of the external wound the nurse was made to count the sponges aloud, my usual custom in ovariotomy. The usual gauze dressing, with straps, was employed. There was no drainage. When the patient was placed in bed, after a two hours' operation, the pulse was 100, and the vaginal temperature 98·2°.

The after-treatment differed in no way from that which I adopt after ovariotomy and similar operations, except that the stomach-feeding was only commenced on the afternoon of the second day—i.e., forty-eight hours after operation—and was then one teaspoonful of ice-water and milk, equal parts, every half hour. The quantity was gradually increased till the afternoon of the next day, when she was able to take two ounces every hour. On the sixth day three ounces were given every two hours. On the fourteenth day cornflour was added to the diet, on the fifteenth day some crumbled bread, and then gradually an ordinary light

Digitized by Google

diet was allowed. During the first week three ounces of beef-tea were injected into the bowel every three hours, with twenty drops of laudanum every six hours, and during certain complications now to be described port wine and quinine were added to these injections.

In the early morning of the day after the operation there was some retching, which occasioned unusually severe pain about the umbilicus; later in the day, hiccough, with vomiting of some brownish fluid, took place; the temperature rose to 100·6°, and the pulse to 126. She still complained of great pain about the umbilicus, which the opium failed to relieve. I had heard in the course of the morning that the nurse who had charge of the sponges had, in spite of the counting at the operation, found her number one short on the previous evening. I now began to have some doubt myself, failing to recollect the removal of a sponge which I had placed under the upper part of the incision while tying the lower parietal sutures. At 2.30 P.M. Mr. Meredith gave the patient some methylene, and under the spray I removed a few sutures, and at once came upon the missing sponge full of dark serum and firmly adherent to the surfaces with which it was in contact. On examination afterwards, and on section, it was found to be already, in less than twenty-four hours, permeated to some depth with organising lymph. Before again closing the incision I passed sponges into the pelvis, and into both loin pouches, and found all dry and clean. I also examined the wound in the stomach, and found it perfectly quiet and free from redness or swelling. The external wound was closed and dressed as before. At the conclusion of this second operation the vaginal temperature was 101·4°; pulse 120. Pounded ice in mackintosh was placed on the head, and next morning the temperature was 99·6° and the pulse 104. All went well after this till the morning of the fourth day, when the ice was removed from the head, the temperature being 98·4° and the pulse 84. In the course of the day she began to complain of pain in the right side of her neck, and the parotid swelled. Later there was soreness of throat on that side and difficulty in swallowing. The evening temperature was 101·4°; pulse 120; respiration 22. The ice-water cap was put on. On the following morning glycerine and belladonna were applied on cotton-wool all over the swelling. Temperature 101·8°; pulse 112. In the afternoon the pain and swelling had become so great that I incised the gland, under the spray. There was no pus, but free oozing of blood and serum reduced the swelling and pain. Evening temperature 102°; pulse 120. The following day (the sixth after operation), the temperature rose to 103°, and pulse to 128. The left parotid began to swell, and was at once covered with glycerine and belladonna. On the following day (the seventh) the bowels were well cleared by enema, and on the eighth day the abdominal wound was dressed and the sutures removed, the whole wound having united perfectly by first intention. The right parotid, which had been dressed daily, began on this day to discharge a little pus. The swelling had entirely disappeared, but the left gland, which had not been incised, remained swollen and painful. On this day there was a sudden increase in the quantity of urine, nearly five pints being passed in twenty-four hours; doubtless this was hysterical, the hair-eating being another manifestation of the same complaint. From this time improvement was rapid, the only trouble being occasional attacks of polyuria. At the end of the second week the swelling of the left parotid had quite gone, and on the following day my incision into the right one healed. She was moved into the convalescent ward on the twentieth day, with a normal pulse and temperature, and was up four days later, leaving the hospital twenty-nine days after the operation quite well. From first to last she had no unfavourable symptom or pain in the abdomen, and when she left there was no tenderness on pretty firm pressure in the epigastrium. Now she is strong and well, and has quite given up eating hair. The mass removed from the stomach was almost entirely matted hair, moulded into the shape of the organ, and it weighed two pounds.

I have never been able to make up my mind whether to attribute the parotid swellings directly to the operation, or whether to look upon them as a chance attack of mumps, from which she had not previously suffered. Most of the cases of this kind which I have either seen or heard of have been distinctly of septic origin; but in this case, certainly, there were no other symptoms pointing in this direction, and I do not believe that the right gland would have suppurated any more than the left, had I not been in too great a hurry to incise it and put in a rubber drainage-tube. Moreover, I have had two other cases in my own practice, which have got quite well without the patients suffering from other symptoms of septicæmia, one case rapidly subsiding without treatment, and one suppurating and requiring incision and drainage. On the other hand, in the particular case under consideration, it would not be at all surprising if the swellings were of septic origin, for many of the sutures in the stomach passed through the edge of the mucous membrane and must have been exposed to the absorption of septic material. The sponge incident is one more to be added to the long list of cases in which foreign bodies have been left in the abdomen in abdominal surgery; it is the second time the accident has happened in my own practice, and in both cases it was fortunately discovered in time to save the life of the patient.[1] When I hit upon the plan of making the nurse count the sponges aloud, I thought I should in future be quite safe, but it seems that the only way in this case, as in many others, is to do it oneself, if one wants to be sure that it is well done. Had I been as responsible as she was, I certainly could not have gone placidly to bed and slept comfortably as she did, telling me casually of the lost sponge eighteen hours after she missed it. The freedom from serious hæmorrhage while making so large a wound in the stomach, and the immediate closure of the wound without any after-troubles from the presence of such a number of silk sutures in the stomach wall, would be surprising had we not already learnt from the resections for malignant disease how much surgery this organ will tolerate.

Shortly after the recovery of my own case I heard that Dr. Schönborn of Königsberg had published a somewhat similar case in Langenbeck's Archives (1883, vol. xxix., p. 609). His incision into the stomach was about the same length as mine, and was closed by two rows of silk sutures. They must have been very close together, for he used sixty-five, and I only used thirty. The operation was thoroughly antiseptic, salicylic spray being used. The patient was quite well in three weeks, and able at that time to eat and digest any ordinary food, even beefsteak. The mass of hair removed was much smaller than in my case, only weighing nine or ten ounces. He gives an engraving of it, natural size. Illustrations of the masses accompany several of the records of cases in which similar masses were discovered after death, and they are all more or less moulded into the shape of the stomach. Schönborn notes in his case that the mucous membrane of the stomach was quite healthy, as it was also in my case. It is very strange it should be so, after long distension with these great rough foreign bodies. The cases of Professor Schönborn and myself are, I believe, the only two which have been successfully treated by operation. Several other cases have been described from post-mortem examination, most of the patients having died from peritonitis, which was in some of them due to ulceration and perforation. Bandamant published a case in the *Journal de Médecine* (vol. ii., p. 507, 1779), the patient being a male who had from a very early age been known to swallow horse-hair; he died, after great suffering, at the age of sixteen. Pollock published in the Pathological Transactions (1851-52, p. 327) the case of a girl, who died at the age of eighteen, with a mass of hair in the stomach measuring 6 in. by 3¾ in., and a smaller mass in the duodenum. She had been known to eat hair since she was three years old. The illustration accompanying this is very like the mass I removed. George May, jun., published a similar case, I believe, in 1865; but I have been unable to find it. Ritchie published one in the *Edinburgh Monthly Journal* (vol. ix.); the patient, a female, died at twenty-one, and the mass weighed 21 oz. Russell published one in the *Medical Times* (1869), which is, perhaps, the most remarkable of the series; the woman died at thirty-one after an abortion, and a matted mass of hair was found in her stomach weighing 4 lb. 7 oz., and dragging the pylorus down into the pelvis; it had been growing for seventeen years, yet she did not seem to have suffered much from its presence, and there was only one small ulcer in the stomach. This case led Inman to publish in the same journal a short note of a case which he had heard of in the practice of Dickinson of Liverpool, the patient, also a female, dying at thirty-four, with symptoms of obstruction. In the same year (1869) Best recorded a case in the *British Medical Journal*, the patient, also a

[1] For note of first case see Proceedings of Medical Society of London, vol. v., p. 37, 1881: also, report of the meeting, THE LANCET, Dec. 13th, 1879, vol. ii., p. 875.

Digitized by Google

female, being thirty when she died, and the mass weighing 30 oz. It is obvious from these records that the condition tends to a fatal termination if not relieved, and its successful treatment is another triumph for the abdominal surgery of our day.

COMBINED DISEASE OF THE POSTERO-EXTERNAL AND LATERAL SPINAL TRACTS.

By C. W. SUCKLING, M.D. Lond., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

B. G——, a labourer, aged sixty-one, was admitted into the workhouse infirmary on August 18th, 1885, complaining of weakness and pains in the legs. No family history of importance could be elicited. He has been a free drinker and much exposed; in 1879 he contracted syphilis. His present illness commenced about two and a half years ago with pains in the legs, more severe in the right, shooting and paroxysmal in character. He has been unable to work for a year and nine months. In July, 1884, he was in the infirmary, and it is recorded on his case papers that he suffered at that time from constipation and "double sciatica," that there were no tender spots in the course of the nerves, and that the reflexes in the lower extremities were slightly increased. In October, 1884, it was observed that the symptoms were those of locomotor ataxy, although the knee-jerk was increased. The Romberg symptom was present, and the gait was somewhat ataxic. The patient was not seen again until his readmission in August last, he then stated that during the last few months his legs had been getting very weak, so that he could scarcely walk at all. At times also he had suffered from girdle pain and severe paroxysms of shooting pains in both legs, and had noticed that he could not control them—they would "kick out"; but latterly his toes caught the ground in walking. He had never suffered from vomiting, pain in the head, or vertigo. For the last few weeks he had been unable to hold his urine, and it dribbled at times.

At the present time the patient can walk with sticks, but he has a difficulty in lifting the toes, which drag, and is quite unable to point them owing to weakness of the extensor muscles. He lifts the feet rather high from the ground and brings the heels violently down, the gait being a combination of the spastic and ataxic types. There are marked swaying movements when he attempts to stand with his eyes closed. He complains of numbness in the legs, and there is complete analgesia and thermal anæsthesia in both; tactile sensibility is perfect both as regards localisation and differential sensibility. There is no well-defined line of demarcation of the analgesia upwards. The muscular sense is unimpaired; he can tell the difference between half ounce and one ounce weights suspended from the toes, knows the position of his limbs, and executes any required movement with precision, his eyes being closed. The plantar, cremasteric, abdominal, and epigastric reflexes are very well marked. The knee-jerk is exaggerated, and vibration of the patellar is marked when the quadriceps extensor is suddenly put on the stretch by depression of the patella. There is slight ankle-clonus on both sides, but no front tap contraction. The left cremasteric reflex is absent. Spontaneous jerking movements of the legs frequently occur and trouble him a great deal. There is no pain in the back at present, no deformity or tenderness anywhere on percussion, and no rigidity. There is myosis of both pupils, which refuse to respond to light, but do so readily to accommodation. The fundus oculi is normal on both sides. Slight incoördination is observed in the upper extremities; he does not guide the fingers to different parts of the face very accurately. The urine is ammoniacal; it contains no albumen or pus. There is, however, considerable paresis of the bladder, the urine constantly dribbling. There are no tremors and no rigidity of the legs; no bedsore or other trophic lesion.

As to the diagnosis in this case. Myelitis in the upper part of the lumbar enlargement would account for the bladder trouble and for the increase of the reflexes below the cremasteric. But this is excluded by the great predominance of the irritative phenomena, and by the very gradual onset of the paresis (two years and a half). The increase of the reflexes was observed before the paresis appeared. Meningo-myelitis or pacchymeningitis with secondary implication of the cord would explain all the irritative phenomena, and by involving the postero-external and lateral columns would account for the ataxic and paretic symptoms. The pupil symptoms would, however, remain to be accounted for. All the symptoms are explained on the supposition that the case is one of combined primary sclerosis of both postero-external and lateral columns. At first the symptoms were those of locomotor ataxy—double sciatica, ataxic gait, and Romberg symptom; then symptoms indicative of implication of the lateral columns, increase of reflexes, spasmodic jerkings, and paresis. The paralysis of the bladder is a point against the above diagnosis, for a moderate degree only of incontinence is observed in tabes, complete paralysis being rare, while in lateral sclerosis bladder symptoms are much less frequently present than in tabes. Charcot insists that double sciatica is always symptomatic, and that its causes are spinal diseases—e.g., locomotor ataxy and meningo-myelitis, diabetes, cancerous disease of the spine causing pressure on the nerves, and disease of the nerves themselves. Westphal reported five cases of this affection in the *Archiv für Psychiatrie* (vols. viii. and ix.). He believes that the lesion does not spread directly from the posterior to the lateral columns, but that the lesions of the two columns are independent. From his cases he concludes that when the lateral columns are affected the symptoms of ataxia are replaced by those of paresis, and not by contracture. In my case no rigidity is present.

CASE IN WHICH A LOUD SPLASHING SOUND WAS PRODUCED SYNCHRONOUSLY WITH CARDIAC ACTION.[1]

By WILLIAM RUSSELL, M.D., M.R.C.P.E.,
LECTURER ON PATHOLOGY IN THE SCHOOL OF MEDICINE, EDINBURGH; PHYSICIAN TO THE NEW TOWN DISPENSARY, ETC.;
AND
J. CORMACK SMITH, M.B., C.M.,
PHYSICIAN TO THE COWGATE DISPENSARY.

Mr. B——, aged twenty-four, a student of medicine, called on Dr. Cormack Smith, of Abbey-hill, on the evening of June 14th, 1885, complaining of pain in the præcordial region and in the region of the left scapula, not extending below its angle, and also of pain in the left arm as far as the elbow. The pain was "numb" in character. In addition, there was a feeling of constriction at the præcordia, and inspiration was so painful that only "half breaths" could be taken. The pain had come on suddenly after dinner, the dinner hour having been 4 P.M. It was so acute that he went and lay down, and he had no sooner done so than the sound to which we shall have specially to refer became audible to himself. The stomach had been out of order for some days previously; there had been an absence of the normal relish for food, and the bowels had been confined. He had never had any illness of importance, and there was no rheumatic history and no history of special injury, although he had had a somewhat severe fall from his bicycle a few years before. There is, however, one interesting point in the history. Three years ago, during the night, a friend who shared his bed was awakened by a noise evidently proceeding from our patient's inside. Becoming alarmed, he roused his friend, and he, with his medical knowledge, referred the sound to his heart, as it was synchronous with its pulsation. It was not accompanied by pain, and in the morning the sound had disappeared. He was quite satisfied that the sound at that time resembled exactly that which we shall presently describe. The only explanation he could offer as a possible cause was that he had walked very rapidly from South Queensferry the previous day.

When Dr. Smith first saw him the pulse was 84, and the temperature was slightly raised, but had fallen to normal the following day. He was kept in bed. On June 21st he was seen by both of us, and we took the following notes of his case. The pulse was 64, regular, small, and thready, readily compressed and obliterated. There was no albumen

[1] Read before the Edinburgh Medico-Chirurgical Society.

Digitized by Google

in the urine. The tongue was furred and the stomach somewhat dilated. When lying on his back a venous pulse was visible above the inner end of the right clavicle, also over the inner end of the left, although less pronounced here than on the right side; there was also supra-sternal pulsation, and pulsation in the upper and outer part of both infra-clavicular regions. The thorax was well formed; both sides moved with respiration, the right slightly more so than the left. The faintest cardiac impulse was perceptible over the præcordia. The hepatic dulness began at the fifth rib. The left nipple was on the fourth rib. Cardiac dulness extended on the left side in the second space for 1½ in. from midsternum, in the third for 2½ in., in the fourth for 3½ in. In the third and fourth right spaces it extended for 2½ in. from mid-sternum. From the fifth to the seventh left rib the percussion-note was more resonant than above that, while below that limit the tympanitic note of the stomach was obtained. In the fourth left space, just within the nipple line, a typical cracked pot sound was elicited by sharp percussion, and was invariably accompanied by an acute pain. Pain was also produced by pressing deeply in this interspace. On auscultation there was a distinct friction sound, synchronous with the action of the heart, and audible over the entire sternum, also over the area of cardiac dulness in the second, third, and fourth left spaces. In the fifth left space, a little within the nipple line, a friction sound was heard intermittently, only during inspiration, but occasionally accompanied by a distinct splash. Towards the site of the cardiac apex a friction sound was present during rather deep inspiration, and influenced by the cardiac action. The second sound was accentuated in both the pulmonary and aortic areas. The foregoing was the result of an examination when the patient lay on his back. He was then turned towards the left side. In this altered position there was visible pulsation in the fourth left space from the nipple line, somewhat inwards, and there was at once developed a sound which was so loud as to be audible at the distance of at least six feet from the bedside. The sound was rhythmical, metallic in character, and somewhat splashing or flopping, not unlike the sound produced by water dropping into a cistern. It was synchronous with cardiac systole. During the sound a limited part of the fourth space bulged, and on its subsidence the interspace faintly vibrated. On auscultation over this spot, the sound was evidently produced immediately under the stethoscope, and was found to be present during both cardiac systole and diastole, and accompanying it was a friction sound, which, however, gave the impression of being distinct from it. The sound, although difficult to describe, was evidently produced by the presence of air and fluid at the site indicated. On palpation the sound could be felt, and entirely gave the impression of being produced under the hand and within an area not larger than a florin. When the patient turned somewhat more on his face the sound disappeared. It is further to be noted that the patient had the power of inducing, or arresting, or modifying the sound within certain limits by apparently allowing the lower part of the thorax and the diaphragm more or less play. He could also occasionally produce a distinct splash by a rotatory jerk of the body when lying down. The assumption of the erect posture often, indeed, as a rule, led to the cessation of the sound.

These are the facts as accurately and fully as they appeared to us; and the question presents itself, How are they to be explained? We begin with the hypothesis that the abnormal sound was produced in a cavity containing air and fluid, and that these were set in sufficient motion to produce sound by the shock both of the cardiac systole and the cardiac diastole. But we may go further, and say that this cavity had an opening, as evidenced by the cracked pot sound elicited by percussion. The question next arises, Where was this fluid and air? It might be in the pericardium, but there appear to us insuperable difficulties to the acceptance of this view. The effect of change of posture is of moment. The sound was produced when the heart was allowed by the position occupied to come into closer relations with the chest wall; and it must be remembered the sound could be *felt* over a very localised area. Had the air been free in the pericardial sac, the position of the patient on his side would have displaced it in a direction which would have tended to diminish rather than to increase its intensity, if not entirely to obliterate it. Further, to explain the cracked pot sound, it would be necessary to assume an opening between the respiratory organs or a hollow organ in the abdomen and the pericardial sac, and that the fluid and air were confined to one part of the sac—that, in fact, it should be encysted, and therefore incapable of displacement by the position of the heart. Equal difficulties surround the attempt to locate the cavity in the pleura or in the lung. There was an entire absence of evidence of antecedent lung mischief, and beyond the pain on inspiration and the pleural friction there was none at the time he was under observation; he did not even have a cough. The next question which presents itself is, Was the sound produced by the action of the heart against a dilated stomach? There is no doubt the stomach was dilated, but this will not explain the evident production of the sound at a point readily appreciable by touch, and so evidently localised. It, further, does not explain the cracked pot sound.

All of these views are to us unsatisfactory, if not untenable. Returning to the hypothesis of a cavity with air and fluid and an opening, we can only explain the phenomena by assuming the presence of a diverticulum from or a hernia of the stomach or large intestine through the diaphragm. By granting this, all the facts are readily understood, and the case would present itself thus: an initial gastric catarrh with dilatation leading to a similar condition of the diverticulum; the retention of air and fluid in it, possibly from a degree of swelling of the mucous membrane at its mouth; while the production of the cracked pot sound by sharp percussion, the finger being pressed deeply and firmly into the interspace, would result from the obstruction at its mouth being still capable of being overcome, although not without causing the patient acute pain. The splashing sound developed by the change of position would thus be due to the heart falling forwards against the cavity; its disappearance as the patient turned more on his face would be the result of the obliteration of the cavity by the weight of the heart. The influence of respiration and of certain voluntary muscular efforts would be due to the position of the diaphragm, and therefore of the diverticulum or hernia which it held. The pleural and pericardial friction would be the result of an irritation originating around the cavity, and gradually spreading outwards and upwards from it. Whether the condition which we have assumed be congenital or acquired we are not at present prepared to hazard an opinion on. The sound was present for nearly two weeks, and its cessation was somewhat sudden. We asked Dr. Bramwell and Dr. Gibson to see the patient, as they are interested in cardiac curiosities, but this was delayed too long, for the sound had not been heard for a day or two before their visit, and had not returned.

THE RATIONAL METHOD OF TREATMENT OF HYDROPHOBIA.

BY SURG.-MAJOR G. C. ROY, M.D., F.R.C.S. LOND.,
CIVIL SURGEON, BEERBHOOM.

THE abortive treatment of hydrophobia discovered by M. Pasteur, if confirmed by subsequent experiments and trials, will confer a boon on mankind not inferior to that of Jenner. It will eliminate from our category of death one fell disease that has hitherto defied the skill of surgeons and physicians alike. The master mind has deducted the result from analogical reasoning, and we are wellnigh in the path of success, though the goal seems to be a little distant. The inoculation of the cultured virus is supposed to give the same protection as vaccination to small-pox, and aborts the real attack of rabies. Unlike many other poisons, the incubative period of rabies is long in its manifestation, and gives sufficient time for inoculation to mature itself and overtake the disease before its development in the system. Hence a man bitten by a mad dog, if inoculated with the cultured virus in the preliminary stage of the disease, is said to enjoy immunity from subsequent attack. M. Pasteur has verified his reasoning by experiment on animals, which, though bitten by mad dogs, did not show any symptom of the disease after inoculation. But inasmuch as all bites are not necessarily attended with fatal consequences, the profession has been sceptical in accepting the theory, and has explained the immunity as a lucky and fortuitous event. However, it seems to be a question of time before the truth will come home to the world and be accepted as a recognised remedy. But it will

Digitized by Google

not [illegible] the lot of the generality of patients to have a laboratory close at hand, and if by chance the bite is overlooked, and the disease actually gains its ascendancy in the blood, have we got any medicine in our Pharmacopœia on which the slightest reliance can be placed for treatment? The full confession in the weakness of our resources will thereby be manifest, and, while brooding over our failures, it [illegible] me that Nature could not be so improvident and callous as to leave us so thoroughly helpless and unprotected.

Starting from the acknowledged action of hydrophobic poison on the blood, can we not find another poison that has [illegible] an opposite virtue and likely to neutralise its effect? We have in the animal kingdom two deadly poisons, which differ entirely from each other in their physiological action. Thus, whilst the poison of snake-bite acts with the rapidity of an electric current, that of hydrophobia takes a long incubative period to mature itself. The effect of both is on the cerebro-spinal system, chiefly the medulla. Rabies produces death by causing spasm of the respiratory centres; snake-poison, paralysis. One causes hyperæsthesia of the cutaneous nerves; the other, numbness. One gives rise to excitement of the brain and furious delirium; the other, coma. In every detail, therefore, of its action, one is in physiological opposition to the other, and, applying the law of analogies, it stands to reason that the effect of one should neutralise the other in the system. Just in the same way as opium and belladonna, being two deadly poisons, their antagonistic virtue was discovered simply on the observance of their different effect on the pupils.

My suggestion may startle the readers as a bold and dangerous practice, but a deadly disease requires a deadly remedy, and we are apt to forget that in the whole range of therapeutics the most potent remedies are the most deadly poisons. But though poisons in ordinary doses, the attenuation of quantity by dilution may yet bring them within the range of remedial measures. It is known that a snake-bite which is not effective to be fatal simply produces a deleterious effect, the symptoms varying in proportion to the quantity of the poison injected into the system. A smaller dose than would produce the physiological effect, instead of bringing on death and destruction. We have, consequently, to hit on the happy medium, and this can be worked out satisfactorily by observing that a good bite of cobra instils ten to fifteen drops of the poison into the tissues. One drop diluted with glycerine and injected subcutaneously, and repeated every two hours according to the symptoms observed, affords a rational presumption for success in the treatment of hydrophobia: thus—snake-poison, twenty-four minims; glycerine, half an ounce; ten drops to be injected every two hours under the skin.

The improvements in medical science in former days were deduced from empiricism. In fact, few remedies were discovered on rational philosophy. I have, on rational principles, suggested the treatment to which I would confidently solicit the profession to give a trial, for it falls to the lot of few to treat one case of hydrophobia from one year's end to the other, and unless the co-operation of [illegible] practitioners be accorded, our life is too short to enable me to establish one single truth in a generation. Cobra poison is plentiful in the rains in India, and, diluted with glycerine, it will keep its virtue intact for a year. I shall be glad to supply the mixture in August next to those who may feel disposed to put the method to the test.

[illegible]TONIN IN AMENORRHŒA.

BY AMAND ROUTH, M.D., B.S., M.R.C.P.,
[illegible] PHYSICIAN TO CHARING-CROSS HOSPITAL, AND PHYSICIAN TO THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.

[illegible] that the re-establishment of the catamenia in amenorrhœa with constitutional disease (especially [illegible]) is helpful in restoring the patient to health, and also that general remedies may be some months before that result, I have tried santonin, as suggested by Dr. Whitehead (THE LANCET, Sept. 5th, 1885)—[illegible] of powdered santonin to be taken on two successive nights. I omitted, however, the morning saline [illegible] to avoid possible sources of error. I have [illegible] twenty cases of amenorrhœa, thirteen of [illegible] with anæmia or chlorosis, and failed completely in seventeen. In all, restlessness, yellow vision, and discoloured urine followed the use of the drug. The following four cases are of interest:—

CASE 1.—Harriet V——, aged eighteen; plethoric and epileptic; has never menstruated. Eight hours after taking the first powder, violent colic with diarrhœa came on, with an unusually severe epileptic fit, during which the menstrual flow appeared, and continued painlessly for four days. She has not menstruated since (three months and a half), but has had one fit.

CASE 2.—Alice K——, aged nineteen; chlorosis; has never menstruated; much ovarian tenderness; slight leucorrhœa. After the two powders a profuse leucorrhœal discharge ensued, lasting six days, with much uterine colic, but no catamenia. Patient is now quite well and regular, after two months and a half of treatment with iron, arsenic, salines, and aloetic purgation.

CASE 3.—Annie B——, aged twenty-one; chlorosis; amenorrhœa three years. The powders produced no effect, but two weeks afterwards three grains of permanganate of potash, with kaolin in sufficient quantity, in form of pill, and taken three times a day after meals, brought on the flow after taking twelve pills. Patient is now nearly cured with the usual remedies.

CASE 4.—Mary E. R——, aged twenty-four; quite healthy; catamenia overdue eight days, though usually regular, and patient is to be married in six days. Catamenia came on during the night after one powder, and for the first time in her life painlessly, lasting the usual four days.

Remarks.—My twenty cases seem to indicate that santonin, as a direct emmenagogue, is useless in amenorrhœa associated with chlorosis, in which cases I have often found permanganate of potash useful. In healthy, or full-blooded women, santonin seems to have some power in starting a uterine flow, and apparently without causing much pain. Its mode of action, however, is quite unknown in this respect, and it seems not likely therefore to be much employed in gynæcological therapeutics.

NOTE ON THE QUESTION OF THE

POISONOUS PROPERTIES OF THE SALTS OF COPPER.

BY CHARLES H. PIESSE, F.I.C., M.R.C.S.,
PUBLIC ANALYST.

THE important question as to whether the compounds of copper are poisonous or not has been recently investigated by M. Dumoulin, Professor of Toxicology in the University of Ghent. A report of the paper he read on the subject before the Belgian Academy of Medicine appeared in the *Semaine Médicale* of the 2nd ult., of which the following is an abstract:—"His first experiments were made on rabbits and dogs, to which he administered doses varying from four to six grammes (sixty-two to ninety-three grains) of copper-sulphate; in no case was the effect serious; the whole of the animals bore perfectly well the ingestion of the copper salts. He next tried the subacetate (verdigris) upon the same class of animals; they vomited at first, but after the administration of further doses the vomiting ceased, and they bore daily doses of the salt during a period varying from six weeks to one year. The carbonate, the oxide, and the oleopalmitate, of which doses varying from seven to fifteen grains were administered, gave equally negative results, the last-named compound being borne with the greatest ease. Toussaint and several German writers had administered to human beings doses rising to seventeen grammes (263 grains) daily of salts of copper without disturbance. It happened that one of the dogs experimented upon by M. Dumoulin was suffering from impetigo. He noticed that the disease disappeared, and attributed the cure to the copper salt. He therefore in the same way treated some children suffering from impetiginous eruption of the face and scalp, and without accident cured the eruption. He then successfully extended the treatment to all forms of scrofulous symptoms, to various superficial skin diseases, ophthalmias, &c. He has now under treatment some scrofulous children aged about five or six years, to whom he administers about one grain of copper sulphate daily, with the result that the

Digitized by Google

manifestations of the diathesis are disappearing. Lastly, he has treated croup, and cured it by the administration of a potion containing from seven to ten grains of copper sulphate taken in teaspoonful doses every half hour till vomiting occurred, then every two hours. In this way about forty grains of copper sulphate have been taken without the least inconvenience, though that quantity should be considered serious to a young child. Brouardel declared long ago that preserves in general, vegetables, &c., greened by a salt of copper, are not in the least dangerous."

The *Analyst* for the current month contains a report of the Proceedings of the American Society of Public Analysts, in which the following paragraph appears: "Dr. Bartley spoke of a case of unmistakable copper-poisoning which occurred in Brooklyn last spring from eating pickles coloured with copper. The victim was a child, who was suddenly seized with severe dysentery and inflammation of the colon. A portion of the pickle eaten by the child was found to contain copper."

Some years ago several samples of canned green peas submitted to me for analysis were found to contain copper, probably in the form of an albumen compound, and were reported by me to be adulterated with some material—to wit, some compound of copper—which would, in my opinion, be likely to prove injurious to the health of persons eating the peas. The Board of Works for the Strand District summoned the vendors for infringing the Act now known as the Sale of Food and Drugs Act. The opinion expressed in my certificates was supported at the hearing of the case by several eminent medical men, including Dr. Tidy and the late Dr. Guy, but was opposed by Dr. Pavy. The Court, however, decided in favour of the Board, since which time the sale of preserved foods tinted green with copper salts has practically been completely suppressed throughout the entire kingdom. The amount of copper varied in the different samples, being equivalent to about two to eight grains of sulphate of copper per pound. The accuracy of the hitherto received opinion, that copper compounds are poisonous, has by M. Dumoulin's experiments been severely shaken, and certainly this question demands further investigation. Wormley, in the "Micro-Chemistry of Poisons" (p. 375), says that "numerous instances are recorded of accidental poisoning by preparations of copper," and also that "the compounds of copper when taken in large doses, or in frequently repeated small doses, are all more or less poisonous." Hence, it would seem from reported cases that though copper salts may not be poisonous, in the generally accepted meaning of that word, yet that the predisposition for poisoning by them is far more common than might be anticipated in the compounds of what is now asserted to be a really non-poisonous element.

MIDDLESEX HOSPITAL.

THREE CASES OF UTERINE FIBRO-MYOMA; TWO REMOVED BY ABDOMINAL SECTION, AND ONE TREATED BY THE ADMINISTRATION OF ERGOTINE.

(Under the care of Mr. HENRY MORRIS.)

THE operation for the removal of uterine fibro-myomata of large size by abdominal section has, during the last few years, been somewhat frequently performed, and the operation is now a well-recognised one, although the mortality is still high. It is an operation which the surgeon will always undertake with a certain amount of anxiety, for until the tumour has been actually inspected it is almost impossible to be confident that the operation can be completed by the removal of the growth. The adhesions may be numerous and dense, or the pelvic portion too large to permit of the application of a clamp below the tumour. The reasons which chiefly influence a surgeon in the performance of the operation are, briefly, rapid growth of the tumour, persistent and severe pain, or severe and uncontrollable hæmorrhage from the uterus. Cases 1 and 2 are examples of the removal of the tumour and greater part of the uterus with the ovaries, and Case 3 of the successful treatment of a tumour by means of ergotine. For the notes of the cases we are indebted to Mr. W. Roger Williams, surgical registrar.

CASE 1. *Removal of the uterus and its appendages, with the tumour, by abdominal section; recovery.*—A tall, spare, healthy-looking, unmarried lady, aged forty-one, was brought to Mr. Morris, on May 20th, by Dr. John Waters of Bloomsbury-square. The abdomen was then greatly distended by a large tumour, which felt elastic, but did not fluctuate. The greatest prominence was on the right side, and there was dulness on percussion over the whole tumour. Vaginal examination afforded only negative information. She complained of a dragging sensation caused by the size and weight of the tumour, and of dyspnœa and faintness on making any exertion. The patient was very desirous to get rid of the tumour on account of the unsightly abdominal protuberance. She said she first noticed slight swelling in the right iliac region about eight years ago, which has since increased to the present size. The catamenia, previously regular, have lately been excessive. On June 30th, with the assistance of Mr. Pearce Gould, Dr. Waters, and Mr. Norton, who administered the anæsthetic, Mr. Morris removed the uterus and appendages, with the tumour, by abdominal section. Tait's clamp was applied to the neck of the uterus immediately above the vagina, and the pedicle thus secured was fixed in the wound. Very little blood was lost during the operation. The tumour removed weighed a little over ten pounds and a half; it was a soft fibro-cystic myoma. The cysts were small, and the softness of the tumour was due rather to the looseness of its texture than to the size and number of the contained cysts. Its bloodvessels, especially the veins, were of great size. The subsequent progress of the patient was uninterruptedly good. The clamp came away on the thirteenth day. The ligatures applied to the uterine vessels were discharged through the external wound about a week later. The patient left London for the seaside, convalescent, at the end of the fifth week after the operation. She is now quite well.

CASE 2. *Removal of the uterus and its appendages, with the tumour, by abdominal section; death from shock; foreign body retained in vagina for three years.*—This patient, a single woman, aged forty-one, was admitted on April 6th, 1885. She was moderately nourished and of dark complexion. The abdomen presented considerable uniform distension; at the level of the umbilicus its circumference was thirty-two inches. On palpation, a smoothly rounded and very elastic swelling was felt, which was slightly movable. There was no fluctuation. On percussion in the middle line of the front of the abdomen, dulness extended from the symphysis pubis to about two inches above the umbilicus. Laterally, the upper limit of the dulness did not reach quite so high. Both loins were resonant. There was œdema of the left leg and foot. The catamenia were profuse and painful. Beyond this and its bulk the tumour caused no inconvenience. On vaginal examination the os uteri was found to be high up and out of reach. At the upper part of the vagina some foreign bodies were felt. The patient said she introduced these three years previously to relieve displacement of the womb, from which a doctor told her she suffered. Subsequently, with a long forceps, a glazed earthenware candle extinguisher and several large pieces of cork were extracted. About seven months ago she first noticed slight abdominal enlargement through her dresses getting too small. She could not localise this primary swelling. During the last two months the circumference of the abdomen had increased by four inches. No injury or other known cause for the disease. Œdema of the left leg was first noticed six weeks ago. The catamenia, which commenced when she was fourteen, continued normal until this illness began, since which they had been profuse and of late painful. She had never had any difficulty in micturition; bowels usually constipated. Previous health indifferent. When three years old the left cornea ulcerated. The seat of the disease was now marked by leucoma, synechia, and capsular opacity. She had been living very badly, substituting ever since the age of sixteen, to some extent, stimulants for food (so her friends stated). She had been subject to palpitation of the heart and faintness. She had never had rheumatic fever. Fifteen years ago she had a severe illness, which her doctor said was dropsy and renal disease; ten years ago she had another similar attack. Four

vomiting, she says, she had "inflammation of the brain." No history of cancer, tumour, or phthisis in the family. At 9.15 P.M. on June 17th, the patient's condition being much the same as on admission, an incision a few inches long was first made in the median line of the front of the abdomen, midway between the symphysis and umbilicus. This exposed the tumour covered with adherent peritoneum. The tumour was not free in the abdomen, but was held back against the posterior wall of the abdomen and pelvis by the peritoneum, which left only its front and sides free. The incision was prolonged upwards and downwards, and a large trocar was thrust into the tumour at a spot which felt very elastic, but no fluid, except a little blood, escaped. The incision was further lengthened, upwards nearly to the xiphoid cartilage, downwards nearly to the symphysis. The bladder was carefully avoided. The peritoneum was next stripped off the front and sides of the tumour, and the tumour was then raised out of the abdomen. On each side of it large vessels were seen, the size of a little finger. These were secured with stout silk. Kœberlé's serre-nœud was passed round the base of the tumour; when it was screwed up the wire broke. Tait's clamp was then applied, and the tumour was quickly cut away. No sooner was this done than the clamp slipped. There was sudden profuse hæmorrhage from half-a-dozen large vessels. These were quickly seized with fingers, forceps, &c., and finally tied with silk ligatures. Tait's clamp was reapplied to the pedicle, which was secured thus in the wound. The loss of blood was not excessive. The peritoneum was sponged out, and the wound closed with superficial and deep sutures in the usual way. Boracic harpie was used for dressing the wound, with strapping and an abdominal binder; carbolic lotion for the hands, instruments, and sponges. The tumour removed was a large elastic, encapsuled fibro-myoma of the cervix uteri. It was about the size of a child's head, and weighed 7 lb. 4 oz. The ovaries and its appendages were adherent to it. The latter was but little altered; both ovaries were normal. There were a few small cysts in each broad ligament. The patient after the operation she was in a state of collapse—cold and clammy. Soon vomiting supervened: she died thirty hours after the operation. At the necropsy, made by Dr. Fowler eight hours after death, a few ounces of blood-stained fluid were found in the peritoneal cavity, and there was extensive retro-peritoneal ecchymosis, especially about the pelvis; this was due to the detachment of the peritoneum, and was beneath the detached portions of the mesentery, which were lying smoothly in place in the abdominal cavity. The vagina was intact. All that remained of the uterus was the portio vaginalis. The ureters were unaffected; both were slightly dilated. Both kidneys showed a moderate degree of sacculation; the renal substance was hard and pale. Spleen small and pale. Liver normal. Old pleuritic adhesions over both lungs. Bronchi contained frothy mucus; their mucous membrane congested. Lungs cedematous. Heart small; the muscular substance pale and soft; the valves normal. The stomach was unusually thin.

Uterine fibro-myoma causing retention of urine, treated with ergotine; recovery.—In September, 1882, Mr. Morris was asked by a medical man to see a patient in great distress from retention of urine, caused by an abdominal tumour. The patient was unmarried, and about forty years old. When first seen the abdomen was greatly distended, and she was suffering severe pain from unrelieved retention of urine of several hours' duration. There was no difficulty in drawing an elastic catheter into the bladder, when about three pints of urine were drawn off. She was then greatly relieved. On examination a large abdominal tumour was found, which was diagnosed as a fibro-myoma of the uterus. The abdominal tumour was of several years' duration. She had previously experienced several attacks of retention of urine. Beyond this, and inconvenience from the abdominal enlargement, she had suffered little. She came to London from Australia, with the intention of having the tumour removed by operation. But the menopause was approaching, and there was no hæmorrhage. Mr. Morris dissuaded her from this, and gave her ergot. She subsequently consulted Sir Spencer Wells, and the ergot was discontinued. She next consulted Dr. Moore of Cavan, who wrote to Mr. Morris for his opinion on the case. In reply, Mr. Morris recommended the continuance of the ergot treatment, which was accordingly carried out, Dr. Moore's wishes, and accordingly it was continued. For four months she took a pill containing one grain of ergotine three times daily; then she took one drachm of extract of ergotine daily for another four months. At the end of this time the tumour had very much diminished. The ergot medicines were, however, not given up, but had been continued up to September, 1885, when Mr. Morris again saw and examined the patient in London. She was then in excellent health, and the abdominal prominence had completely disappeared. On deep pressure over the hypogastrium a small hard lump was felt. On vaginal examination the uterus was found heavier and larger than normal. In a letter to Mr. Morris, Dr. Moore said he was sure the disease was starved out in the patient. He had had three other similar cases, and now after a lapse of ten years there had been no return of the tumours, and the patients are now in perfect health.

GENERAL HOSPITAL, WOLVERHAMPTON.

ACUTE INTUSSUSCEPTION; INFLATION AND INJECTION OF BOWEL; RECOVERY.

(Under the care of Mr. F. E. MANBY.)

FOR the following notes we are indebted to Mr. J. W. Batterham, B.S., F.R.C.S., house-surgeon.

Benjamin H——, aged five years, was admitted at 3.30 P.M. on Feb. 8th, 1885. His mother said that the child was quite well till an hour before admission, when he was suddenly seized with violent pain in the abdomen. Soon afterwards he wanted to go to stool, and there he passed "a teacupful of blood" from the bowels. Alarmed by this occurrence, the mother immediately brought the child to the hospital.

On admission, the little patient, a well-nourished and apparently healthy child, lay in bed on his right side, with his legs drawn up, pressing his abdomen with both hands just above the umbilicus, where he complained of great pain and tenderness. On abdominal palpation a tumour of elastic feel was discovered. Its shape was, roughly, that of a cylinder, 5 in. long by 2 in. in diameter, bent upon itself at an angle of 120°. Commencing at the level of the right crista ilii, it could be traced upwards along the line dividing the right lumbar from the umbilical region till it bent round the umbilicus, and ended an inch and a half above and to the left of it. The tumour could be moved laterally over an area of about two inches, but allowed of no movement in a vertical direction.

After admission the patient vomited some semi-digested farinaceous food. At 5.30 P.M. the patient was put under chloroform, and the large bowel was inflated with air. This producing no sensible effect on the tumour, olive oil was injected until the colon was seen and felt to be largely distended. By this means the tumour was reduced to three inches in length and confined to the right lumbar region. Further injection being thought unadvisable, the patient was returned to bed, belladonna fomentations being applied to his abdomen. At 8.30 P.M. the tumour was found to be only an inch and a half in length, and to occupy the lower part of the right iliac region. As it was being examined it was felt to slip from beneath the fingers, communicating a sensation similar to that experienced on the reduction of a hernia. No trace of the tumour could then be found.

On the next day the patient appeared cheerful, was no longer pallid, and had no abdominal pain or tenderness. Oil and fæces were passed per anum. There was no blood in the stools. No vomiting had occurred since the previous afternoon.

The patient was kept in bed on low diet for a few days, and discharged quite well on February 8th.

FRACTURE (?) OF THYROID CARTILAGE; LARYNGOTOMY; RECOVERY.

James W——, aged sixty-four, was admitted under the care of Mr. Manby, on the morning of June 18th, 1885. On the evening of the 15th the patient awoke from an alarming dream, and, springing out of bed, fell and struck the front of his neck against the sharp edge of a chairback. He stated that "the lump in the middle of the neck" (pomum Adami) was "driven in" and that he was almost suffocated, but ultimately succeeded in drawing "the lump" back into position with his thumb and forefinger.

On admission, he complained of increasing dyspnœa (which was "worse at times"), dysphagia, and slight cough, with expectoration of blood-stained mucus. On examina-

Digitized by Google

tion of the patient's neck, the larynx was found to be median in position. Considerable swelling and ecchymosis were visible over the right side of the thyroid cartilage, the ecchymosis extending across the middle line at the level of the crico-thyroid membrane. No pain was complained of on handling the hyoid bone. Manipulation of the larynx was painful, but elicited no crepitus. Laryngoscopic examination (which was difficult by reason of dyspnœa) revealed no œdema glottidis, nor was any obstruction seen between the vocal cords. The latter were congested, and the right cord was a little nearer the middle line than the left. The patient's voice was hoarse and his respiration laboured; both inspiration and expiration were noisy. The lower intercostal spaces receded with inspiration.

An hour after admission the patient, who had been put to bed in a warm ward, was seized with an attack of urgent dyspnœa, and became intensely cyanosed. Laryngotomy was immediately performed, without an anæsthetic, and a Fuller's bivalve tube introduced. The patient was placed in a steam tent, and the dyspnœa was markedly relieved.

The further progress of the case is shown by the following notes from the bed-card:—June 19th: Passed a good night; respirations 20; muco-purulent expectoration through the tube.—20th: Pulse 76, regular, of good volume and force; respirations 22; liquids are swallowed readily. The swelling on the right side of the larynx is diminishing. The tube was removed at midday, forty-eight hours after its introduction. He can breathe well through the wound, but cannot bear it closed.—21st: The cough is less; can breathe a little when the wound is closed.—23rd: Swallows solid food without much difficulty; breathes easily through the glottis; edges of wound drawn together with strapping; steam kettle discontinued.—24th: The patient gets up and walks about the ward.—July 1st: The wound was quite healed, and the patient discharged.

Remarks by Mr. J. W. BATTERHAM.—It is difficult in some cases to diagnose accurately the lesion produced by a blow on the larynx. The only symptom of fracture of the cartilages not present in mere contusion is crepitus, and this is not appreciable in all cases. The reasons that would lead us in this instance to suspect fracture are the age of the patient and the violent nature of the injury. In addition to the fact that all the eleven cases of fracture of the cricoid cartilage reported in Holmes's System were fatal, the position of the external marks of violence render it probable that the thyroid cartilage was the site of the lesion.

PATHOLOGICAL SOCIETY OF LONDON.

Sarcoma of the Tongue.—Malignant Disease of the Œsophagus.—Joint Disease in Animals.—New Growths in Heart and Viscera.—Tubercular Exfoliating Cystitis.—Aneurysm of Mitral Valve.

THE annual general meeting of this Society was held last Tuesday, Dr. J. S. Bristowe, F.R.S., President, in the chair.

Mr. F. EVE showed two specimens of Sarcoma of the Tongue. The first was a Hunterian specimen, at least 100 years old. It was a rounded tumour, situate in the left side of the base of the tongue, and directly continuous with the subjacent structures; the mucous membrane over it was slightly altered. The tumour contained wavy fibrous tissue at the base, and above this groups of clear round cells. Many dilated lymphatic sinuses were to be seen in the deep layers of the mucosa. The tumour was probably a fibro-sarcoma; it had some resemblances to the case recently exhibited by Mr. Jonathan Hutchinson as a lympho-sarcoma. The second specimen was a distinctly encapsuled tumour, and consisted of fibrous tissue, with spindle and round cells.

Dr. PRICE showed a specimen of Carcinoma of the Œsophagus, taken from a man aged fifty-seven, who had suffered from dysphagia for eight months. He complained of pain in the back. The cervical glands were enlarged, and especially in the left posterior triangle of the neck. Temporary œdema of the left upper limb was also noticed, probably due to obstruction of the left innominate vein. The superior mediastinum contained a large mass of new growth, that surrounded the aorta and spread upwards into the root of the neck, involving various structures. A sloughy-looking ulcer on the level of the bifurcation of the trachea was found in the œsophagus, and there were two openings leading into the submucosa. There was a secondary nodule in the liver. The extensive affection of the glands of the neck and left axilla was remarkable.—Mr. CHARTERS SYMONDS made some remarks on the tube worn by the man, and thought that the second opening in the submucosa might equally well have been caused by ulceration as by the tube.

Mr. J. B. SUTTON read a paper on Injuries and Diseases of Joints in Animals. Dislocations of joints were very rare in animals, and but few cases were on record. An example of old unreduced dislocation of the hip-joint in a cat was exhibited, and also the epiphysis of the head of a femur taken from a two-year-old horse. The latter specimen was singular, for after the accident the horse walked without betraying any evidence of lameness, but when trotted always limped; it lived for many months. At the autopsy the epiphysis was found quite separate, and all movement had taken place between the neck of the femur and the epiphysis, which had in consequence become eburnated and smooth. A specimen of pulpy degeneration of the knee-joint from a capeybara was exhibited, and reference was made to a case of Pott's disease in a monkey. Of all forms of joint disease, none were so frequent, so ancient, or zoologically so widely distributed, as osteo-arthritis. Specimens illustrating the affection were shown in the vertebral column of a snake, llama, and a horse, and in the knee-joint of an antelope. Specimens in the museum of the College of Surgeons proclaimed the disease in an ostrich, white bear, and lion. The affection had been seen in cats and dogs. In the museum of Trinity College, Dublin, is a skeleton of the extinct megaceros said by competent observers to present traces of this affection. A curious symptom associated with this form of joint disease in animals, and probably in human beings, was the early fall of the teeth, due to abnormal absorption of the alveolus. Paraplegia caused by disease, affecting the spinal column was very frequent in animals, some of the cases possessed considerable interest. In rickets paraplegia arose from two causes; in very young animals, from actual softening of the bone, causing the vertebræ to yield under the weight of the body. If rickets affected an animal at puberty, the epiphysial lines of the vertebræ bulge and compress the cord, as by a series of tumours. An interesting case occurred in a tiger that had received an injury to the atlas six years before. The fracture never repaired, except by fibrous tissue, but exuberant callus and the gradual yielding of the transverse ligament allowed the odontoid process slowly to compress the medulla, and produced complete paraplegia. An example of dislocated atlas that produced paraplegia in an ichneumon was also exhibited, and also a case of paraplegia produced by disease of the cord in a civet cat; it was associated with sclerosis of the nerves of the limbs, and with a typical perforating ulcer on the fore-paw. These investigations went to show that there were few diseases of joints peculiar to man, gout being probably wholly human.—Dr. NORMAN MOORE had not seen any compression of the spinal cord in cases of human rickets. He referred to a form of paraplegia to be observed in dogs after distemper; it resembled the weakness of the legs, such as might be seen in diphtheritic paralysis.—Dr. GOODHART inquired whether there was any new growth about the perforating ulcer of the cat's paw.—Dr. DAWSON WILLIAMS said that stringhalt had recently been attributed to peripheral neuritis, and inquired whether Mr. Sutton could state the condition of the nerves in his cases.—Mr. J. B. SUTTON said that in man the epiphysial plates were very slight as compared with those of some animals, and so compression of the cord from overgrowth was not likely to occur in rickety children. On the other hand, mere softening of the vertebræ might, even in human beings, cause paraplegia. He would examine the thick rim of the perforating ulcer for new growth. "Stringhalt" was a term that covered a whole group of anomalous symptoms, and we had the clue to but one in the cases of osteo-arthritis; sometimes it was due to disseminated sclerosis; it had resemblances with chorea, which Mr. Horsley had recently shown in the dog to be due to disseminated sclerosis.

Dr. NORMAN MOORE showed specimens of Cancer of the Heart. The first case was that of a man aged forty-one, who died after an illness of five months. The heart contained several masses of a firm whitish new growth embedded in its substance, and extending from the pericardium to the endocardium. The largest mass was in the anterior part of upper wall of the left ventricle. The microscope revealed the epithelial structure with abundant dense stroma. The new growth involved the lungs (not the bronchi), the diaphragm, lumbar glands, and kidneys. The primary growth was probably in the right kidney. The second case was that of a man aged fifty-seven, who died after an illness of eight weeks. The heart contained a single mass of firm whitish new growth in the upper part of the anterior wall of the right ventricle. The pleura, peritoneum, liver, kidney, suprarenals, lumbar glands and œsophagus were also the seats of cancer. The carcinoma was probably primary in the gullet, though there was no evidence of stricture during life. The third specimen came from a women aged sixty-four, who died after an illness of four months. The heart contained many masses of new growth, and the pericardium was involved. Cancerous nodules existed in the skin, cervical glands, lungs, pleuræ, peritoneum, thoracic and abdominal glands, spleen, surface of liver, and in the remaining abdominal organs. The skin was probably first affected. No symptoms pointed to cardiac disease during life. All the cases were carcinomata of somewhat rapid growth, less than six months; and it was worthy of note that in all the kidneys as well as the heart contained carcinomata. In eighteen cases of œsophageal cancer the heart was found to be involved twice, and the kidneys were also affected.—Dr. PYE-SMITH said he remembered Dr. Wilks had alluded to the frequency with which the kidneys were affected when the heart was the seat of abscesses in cases of pyæmia.—Mr. A. A. BOWLBY had recently examined two cases of scirrhus cancer of the gullet, in which the kidneys were the only seats of secondary growth.—Dr. J. S. BRISTOWE did not himself think there was any special connexion between the heart and kidneys. In his experience also cardiac cancer had been without symptoms.—Dr. NORMAN MOORE, in reply, remarked that Queen Catherine of Aragon died with melanotic cancer of the heart, with symptoms which led to the belief that she had been poisoned.

Mr. E. H. FENWICK showed a specimen of Tuberculosis of the Kidneys, Ureters, and Bladder. The man had suffered from several attacks of renal colic in the right side, also hæmaturia and very frequent micturition. Nephrotomy relieved the tension of the pus in the pelvis of the right kidney, and then pyuria became a symptom. Nearly the whole of the mucous and submucous tissue of the bladder (with the exception of the mucous membrane of the trigone) had been exfoliated. The irritability of the bladder probably received some explanation from this circumstance.

Dr. SAMUEL WEST exhibited a specimen of Aneurysm of the Mitral Valve, taken from a man aged thirty-four, who had suffered from rheumatism first at the age of fourteen. An oscillating temperature, varying between normal and 105° F., was an important symptom. An external squint, with nystagmus, was also reported. Abscesses of embolic origin were found in many organs, and one in the middle of the right lateral lobe of the cerebellum, which was probably the cause of the nystagmus. There were numerous vegetations on the aortic valves, and one large pear-shaped mass must have come into incessant contact with the aortic flap of the mitral valve, on the aortic aspect of which a minute opening into an aneurysm could be seen. The aneurysm was filled with clot, and was of the size of a Barcelona nut. He showed three other specimens of aneurysm of the large flap of the mitral valve. The rarity of aneurysm of the mitral valve was a part of the interest of the specimens, which also illustrated exceedingly well the mode of formation of those aneurysms originating in the fibroid structure of the heart. Many of the incipient aneurysms possessed the exact shape and size of the vegetations which, by their incessant friction, constituted the chief cause of production of the aneurysms.

The following card specimens were shown:—Dr. Hale [illegible] Hæmorrhage into the Sheath of the Optic Nerves. [illegible] Edwards: Carcinoma of Bladder. Mr. [illegible] Fracture of the Tibia and Fibula into the [illegible]. F. S. Eve: (1) Large Urinary Calculus [illegible] by a girl; (2) Ectopia of the Crop of [illegible]:

MEDICAL SOCIETY OF LONDON.

The Lettsomian Lectures.

AT the meeting held on Monday last, Dr. Wm. Ord, President, in the chair, Mr. Jonathan Hutchinson, F.R.S., delivered the first Lettsomian lecture, on "Some Moot Points in the Natural History of Syphilis."

Mr. J. HUTCHINSON said that if the question in debate could be once clearly stated the duality or unicity of venereal poisons would soon cease to be a moot point. No one thought there were two forms of syphilis, and no one doubted that there were two kinds of sores. Were they related or independent? Bassereau proved that chancroids were very contagious, and always produced sores like themselves. This process of syphilisation was, however, only done on those who had had syphilis. This was a fallacy, for the patient might, in consequence of his prior syphilis, be insusceptible of fresh contagion. Danielsen, in Bergen, inoculated a number of lepers who had never had syphilis, and with similar results. Mr. Hutchinson insisted on the difference between a specific poison and a specialised poison. All inflammatory products were probably under favourable conditions contagious; the contagium might be a product of an inflammation that had originated spontaneously. It is possible that the poison which produces the chancroid is, after all, only a specialised inflammation product, and not a specific virus. Soft sores might be a mere appanage of syphilis. Many of the soft sores wanted the typical characters of a chancroid, and the absence of induration was the most universal characteristic. This want of uniformity, and the fact that the true chancroid on the genitals is seldom seen excepting in those who have had syphilis already, were strong arguments against specificity. If a person who has never suffered before contracts a venereal sore of any kind, it is highly probable that it will tend to syphilis. Dr. Morgan's (Dublin) experience placed this fact in a strong light. Thus it would seem that insusceptibility is a usual cause of non-occurrence of induration. In using this argument he did not wish to deny that the typical chancroid is sometimes seen in those who have never had syphilis. Important evidence as to the origin of the chancroid and of all non-indurated venereal sores from syphilitic secretions was afforded by the experiments of Morgan, who inoculated syphilitics with purulent vaginal fluid of syphilitic women. Mr. H. Lee had shown that artificial irritation of a true chancre gave rise to a purulent secretion which is inoculable in the patient, producing a sore not distinguishable from chancroid. A parallel might be drawn between the chancroid process and phagedæna. All will admit that syphilitic inflammations have a remarkable tendency to become phagedænic. There is reason to believe that the chancroid type of inflammation might be only a kind of minimised phagedæna, and differ only in degree. If the virus of a chancroid be not specific, it is at least well specialised; and chancroids are very contagious, and reproduce themselves with closely similar features.

Mr. Hutchinson next dwelt on the relations of hospital phagedæna to syphilis, and said it was not uncommon to see the disappearance of hospital gangrene claimed as one of the triumphs of antiseptic practice. He held this to be a mistake, whilst believing strongly in antiseptic surgery. Evidence in the form of clinical cases and outbreaks of hospital phagedæna was brought forward, showing that syphilitic sores could always, and even in unlikely instances, be made to account for the occurrence of hospital gangrene. Hospital phagedæna is very contagious, and spreads by contagium only; the previous health of the patient matters nothing, nor the salubrity of the ward. It never leads to constitutional syphilis. Accepting the hypothesis of its syphilitic origin, we have, then, a parallel fact to what is observed in the case of the chancroid. A specialised contagium has been bred up which can produce its like whenever inoculated, but which does not contain the virus of syphilis. It is easy enough to see that, if once the particulate virus of syphilis have died out of a secretion, the latter may then be propagated *ad infinitum* without the slightest possibility of reproducing the defunct elements. Mr. Hutchinson held that true chancres were the most likely to be attacked by phagedæna, and he believed that it occurred at a stage too late to prevent absorption. Phagedæna was a concomitant of a true syphi-

Digitized by Google

litic inflammation, and did not usually occur until induration had taken place. It denoted unwonted susceptibility to the influence of the virus, and was often followed by severe secondary symptoms. A knowledge of the fact that phagedæna usually accompanied true syphilis was of great importance in retrospective diagnosis in medical practice. Mr. Hutchinson believed that a scar or the remains of a phagedæna more often meant syphilis than not. Moreover, scars in the groin were most likely syphilitic. In private practice inflamed buboes were rare. It was not very exceptional for a typical chancroid to cause no enlargement of the glands. He could not lose sight of the fact that a great many infecting sores did inflame and suppurate, and when that was the case the glands would follow suit. In a group of six infants suffering from syphilis, the result of circumcision, no less than two had suppurating buboes, and another had large masses of agglutinated glands. He considered it possible that age and personal peculiarities often exercised great influence in the tendency to inflammatory action. The recognition of non-infecting venereal sores on other parts than the genitals, whether on the hands or elsewhere, was a matter of great difficulty. Mr. Hutchinson had never yet seen a suppurated bubo in the arm-pit in association with a venereal sore on the hand. So remarkable a fact might mean that the soft sore was very rare on the fingers, or that it very rarely caused bubo. Probably there was truth in both statements. Speaking of second attacks of true syphilis, Mr. Hutchinson referred to Ricord's statement of 1839, that an individual who had once had syphilis was not liable to it again. But in 1859 Ricord admitted, what several observers have subsequently asserted, that second attacks were possible. The interval was generally long, and might be as long as twenty years. Mr. William Allingham published an interesting case, in which a man contracted syphilis in February; the induration of the primary chancre disappeared under mercurial treatment. In May a rash and sore-throat appeared, and mercury was again taken. Having left off the mercury for a month or more, he returned in July with another chancre, which was believed to be the result of fresh contagion; the second chancre was not in the site of the former one, but presented the most characteristic induration. This sore was followed by rupia and periostitis, and yielded but slowly to mercury. Mr. Hutchinson admitted the difficulties of the case, but felt sure that we not unfrequently encountered most startling exceptions to general rules.

Treating next of periods of incubation, Mr. Hutchinson gave his own experience as leading him to believe that the period was a more or less definite one of four or five weeks, thus differing from Sigmund of Vienna and Ricord. Berkeley Hill said that twenty-four days was the average, but from ten to forty-six days were the limits. In the case of a medical man who had vaccinated himself in the forearm from a syphilitic infant, the punctures, which had quite healed, became irritable on the twenty-first day, and were well indurated on the forty-first. Coming next to recurrent chancres, Mr. Hutchinson said he was the first, he believed, to draw attention to the very curious group of cases which illustrated recurrence, but two years after his brief paper Fournier wrote a masterly account. It was quite possible, and not a very rare occurrence, for indurations to develop in the retro-coronal fold of the prepuce which were not consequent on any fresh contagion. They usually, but not invariably occurred in the site of former chancres. They might occur at very various periods after syphilis, but ordinarily within five years. He thought that too much importance had been attached to the condition of induration as an almost essential characteristic of the initial lesion of syphilis. The absence of induration went for very little in the way of evidence. In many cases induration lasted but a short time. It was often ill marked in women, and its characteristics varied much in relation to the special tissue affected. If we admitted this, we might still hesitate to admit that syphilis could begin without any chancre whatever. Yet, for practical purposes, that was the conclusion to which we must come. No doubt a slight sore might be overlooked. Was it possible that intra-urethral chancres might occur without pain or signs of obstruction, and without external hardening and without discharge? Such was the suggestion of some, but it did not seem very probable. The frequent occurrence of cases in which syphilis followed what was considered to be only gonorrhœa suggested the suitability of recognising what we might call gonorrhœal syphilis. In explanation of facts adduced by Lee and Berkeley Hill, it might be admitted at once that there was nothing in the least improbable in the supposition that the particulate virus of syphilis might exist in gonorrhœal pus. Basset and Tamorowsky, both quoted by Berkeley Hill, made experiments apparently proving that gonorrhœal pus either from the male or the female could not induce a chancre followed by syphilis. Their experiments were made on non-syphilitic subjects.

The last question on which Mr. Hutchinson touched was the possibility of the conveyance of syphilis by translucent vaccine lymph. The belief that it was necessary to draw blood, or at any rate to allow the vesicle to drain after emptying it, and thus permit the escape of fresh leucocytes, could no longer be entertained. The fact that apparently pure lymph from vaccinia of a syphilitic infant could cause true syphilis in a non-syphilitic individual must be held to have been proved as the result of some inoculations made on himself by a member of the medical profession (this was an allusion to a case which has already been made public). The interest of this demonstration did not end with its relations to the practice of vaccination. It proved that the virus of syphilis might exist in a perfectly clear fluid and in company with that of another specific fever.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Cases of interest from the late War in the Soudan.—Antiseptic Surgery at the West London Hospital.

AT the meeting held on December 4th, 1885, Mr. W. B Hemming, President, in the chair,

A paper was contributed by Surgeon HAROLD HENDLEY, I.M.S., and read by Mr. DUNN, on "Some cases of interest from the late War in the Soudan." The paper consisted of five cases, in four of which operative interference was followed by exceedingly good results.—Case 1: Bayonet wound. A bayonet which had transfixed the left arm through the biceps had also caused an apparently superficial wound of the chest, in the mid-axillary line immediately below the seventh rib. There were no signs during life of penetration of the thorax or injury to the lung. The man, contrary to orders, left the hospital in the course of an hour, and after three hours had elapsed difficulty of breathing supervened and death occurred from asphyxia. At the post-mortem extensive pneumothorax was found, with collapse of both lungs. There were four ounces of venous blood in the left chest, and there was a small wound of the lower lobe of the left lung.—Case 2: Bullet wound (Remington rifle). An Indian mule-driver, aged twenty-eight, was admitted with a bullet wound of the right thigh and left foot. The bullet had passed into the foot immediately in front of the astragalo-scaphoid articulation, where, upon several previous occasions, unsuccessful attempts had been made to find it. Under chloroform, careful digital examination and the use of Nélaton's probe having failed to establish the whereabouts of the missile, the patient was placed in the position in which he was supposed to have been in when the injury was received, and then palpation of the foot revealed an oblong mass in the sole of the foot; this swelling was cut down upon and proved to be the bullet. The patient was subsequently invalided to India and did well.—Case 3: Suture of tendons and the median nerve. A Greek wasadmitted from one of the field hospitals for a deep horizontal sword-cut across the front of the right wrist, in consequence of which some time previously it had been considered necessary to resect the lower end of the radius. On admission there were complete loss of sensation over the parts supplied by the median nerve, and but limited power of movement of the hand. The wound was reopened, and the median nerve, after some dissection, together with the tendons of the flexor carpi radialis and palmaris longus, were found widely separated; the ends were pared and catgut sutures used to bring them into close apposition. The hand was fixed upon a splint in a flexed position. The wound granulated well, and ultimately the man was discharged with complete recovery of sensation, except over two small patches, and with daily increasing power of movement.—Case 4: Ununited compound fracture of the radius and ulna. A native of India, aged twenty, was admitted with this injury, which had been caused by the bite of a camel. The patient had been under treatment for some time without any union taking place in the bones in question. Under chloroform, the ends of the bones were resected, and holes drilled through the fragments; the latter were then approxi-

Digitized by Google

nated with silver wire, the ends of the wire being left projecting from the wound. The patient was afterwards invalided to India, with every prospect of good union taking place.—Case 5: Malignant-looking ulcer of the pubes of 180 days' duration. The ulcer measured 3½ in. vertically and 2½ in. transversely. Its edges were irregular, raised, rounded, hard; base firm, indurated; inguinal glands slightly enlarged. Under chloroform, the mass was removed, after which a flap of skin was brought down from the right of the middle line, twisted at its base, and attached by its free end to the loose skin of the penis, so that the wound was almost wholly covered. The patient was subsequently invalided to India, and was soon quite convalescent. The dressings used were carbolised oil lint and iodoform tenax.

Mr. KEETLEY read a paper on Antiseptic Surgery at the West London Hospital. During the years immediately preceding and including 1880 the course of wounds had been so unsatisfactory that towards the end of that year the staff held meetings to consider the matter. These resulted in recommendations for the provision of better means of carrying out antiseptic surgery and certain minor improvements in the drainage and ventilation. The drainage is, however, to this day old-fashioned, and the faults of ventilation are not very materially removed. Anything like systematic registration of cases in detail had been absent from the hospital till recently, so the only reliable statistics the author possessed were those of his operations. In the first five years ending August, 1881, he had only sixty-nine operations to record; eleven of the patients died. He now became acting full surgeon, and in the year immediately following, the improvements as regards provision of antiseptic materials &c. having taken place, he had seventy-five operation cases and no death. In the period of four years and a quarter from August, 1881, up to the present, he had had 438 operations with 16 deaths. The percentage of mortality was therefore in the first period 16, and in the second 3·6. The fatal cases were then considered in detail, and it appeared that the majority in the first period might be referred to septic causes, while an entirely different state of things prevailed in the second period. The class which bore the most striking testimony to the value of antisepticism was that of operations affecting the larger bones and joints; of these the author had performed, since January, 1881, 235, with the loss of only four patients in the hospital, and a fifth who died shortly after leaving it. All the fatal cases were complicated in the most serious manner, one being a double amputation of one leg and the other thigh; one being a patient with advanced phthisis; two having died of tubercular meningitis when they were far advanced in convalescence from the operations which had been done; and a fifth died, seven months after being trephined, of cephal-hydrocele. The 235 bone and joint operations included twenty-two major amputations, all but four through the lower extremity, with one death (in the previous period there were seven major amputations with four deaths); seventy-four osteotomies, with no death (in the preceding period only one osteotomy, which inflamed and suppurated seriously). Of the osteotomies, twenty-three were of the hip and 32 of the femur near the knee-joint; fifteen excisions, including three of the hip, five of the knee, and three of the elbow; seven excisions of tarsal and carpal bones; seventeen partial excisions and erasions of the larger joints, including seven of the hip and five of the knee; many cases of antiseptic drainage of the larger joints; eight sutures of the patella; seven scrapings out of the medulla of long bones (the femur five times); three direct operations for caries of the spine; four for malunited and ununited fractures (femur and tibia), &c. The other classes of cases, such as excisions of tumours, myotomies, and rectal and genito-urinary cases, caused no death, and otherwise showed a clean sheet, except as regarded about one case of erysipelas. An account was then given of the antiseptic methods practised at the West London Hospital. This showed a transition from strict use of the spray and carbolic gauze dressings, through what might be described as an iodoform period down to the present time, when the douche and turf moss pads charged with sublimate were being used. But Listerian principles had never been lost sight of, and the author believed that the choice of any particular antiseptic appliances was far less important than thoroughness in the use of those chosen. Lastly, he stated that the results and principles of his colleagues did not essentially differ from his own. They were now all antisepticists at the West London Hospital. — Dr. SINCLAIR THOMPSON said he was a strong believer in antiseptics. He approved of the douche, but now discarded the spray.—Mr. TUKE described a case of sebaceous tumour of the scalp, which the patient refused to have removed. The cyst suppurated, and the cyst wall was taken away. No antiseptics were used, and the patient died in six days of symptoms of blood-poisoning.—Dr. ALDERSON did not think that in small operations, such as the removal of sebaceous cysts, antiseptics were necessary. The worst case of amputation of the breast which he had seen was one in which strict antiseptic precautions had been taken.—Dr. THUDICHUM said that where perfect cleanliness was observed no cases of hospital gangrene were met with. He described a visit to a continental hospital where the wounds invariably failed to progress favourably, and this was distinctly traced to dirtiness of the bandages, forceps, and splints. In alkaline solutions salicylic was not an antiseptic.—Mr. EDWARDS did not use the spray, except in operation upon serous and synovial sacs. He thought cleanliness a very wide term. It was immaterial what the description of the antiseptic was which was used. The cardinal features of wound treatment were pressure and drainage, and in this connexion he strongly advocated Esmarch's bandage.—Dr. POPE was glad that Mr. Keetley had discarded the spray. He related a case in which a knee-joint had been opened five successive times without it.—After some remarks from Dr. BALL, Mr. KEETLEY replied.

Dr. SINCLAIR THOMPSON read an interesting paper upon a Trip which he had taken to Suez and back, and advocated strongly the advantages of a short sea voyage for the purposes of health.

CAMBRIDGE MEDICAL SOCIETY.

Friedreich's Ataxia.—Embolism of Central Artery of Retina.

AT the meeting held on Nov. 6th, 1885, Dr. Bradbury, M.D., President, in the chair,

Dr. MACALISTER narrated a case of Friedreich's Ataxia. The patient, a labourer, aged twenty-nine, single, was admitted to Addenbrooke's Hospital in July, 1885. The father is living, but the mother died twenty-two years ago, complaint unknown. One brother alive in America, believed to be well; one brother died, having been "afflicted" like the patient; two sisters are also "afflicted." Patient thinks he was "queer in his legs" about the age of nineteen, but could do his work till three years ago. Then he began to feel weak in his legs, and dizzy at times. This gradually increased till eighteen months before admission, when he lost all power in his legs. During this time he suffered from backache, but has never had pains of any kind in the limbs. His speech also has gradually altered. He had to go to the workhouse more than two years ago, and has gradually got worse. On admission his legs were found to be somewhat wasted; organs appeared sound. He could not stand even with his eyes open, nor move his legs and toes when lying or sitting. No abnormality of sensation. Patellar reflex entirely absent; no ankle-clonus; skin reflexes apparently normal. He had complete control over bladder and rectum. His head was in constant slow motion from side to side; he had a slight convergent squint. Complained only of backache, and of (apparently flatulent) distension of abdomen. No trace of syphilitic disease. Urine normal. Pupils reacted both to accommodation and to light; the fundus appeared normal. The back showed a slight lateral curvature of the dorsal and lumbar spine to the left, but the ribs did not bulge and the transverse processes could not be felt. Speech slurred and drawling; no aphasia. He was given small doses of liquor strychniæ. On Aug. 11th the arms began to be ataxic, especially marked in attempts to write. Five-grain doses of iodide of potassium were ordered. On the 30th he complained of seeing double when looking at distant objects, and had pain in the right eye. The right pupil was somewhat dilated and sluggish in reaction; left optic disc not quite clear; slight nystagmus. On Oct. 1st ataxia of the hands and arms was very marked, and the speech was very drawling and indistinct. Legs weaker.

Mr. DEIGHTON remarked on a case of Embolism of the Central Artery of the Retina. On Feb. 2nd, 1885, he was sent for to see a woman, aged sixty, who said that as she was lying awake in bed in the morning she suddenly lost the sight of her right eye. She had never had any previous attacks of loss of sight or even of temporary dimness, and the other eye was

Digitized by Google

not affected when this went blind; she did not feel giddy, faint, sick, or have any sensation of pain at the time of the attack. Never had rheumatic fever, chorea, or suffered from fits of any sort. There was no albumen in the urine; the heart sounds were healthy. She had suffered for years with a cough; the apex of one lung presented well-marked evidence of phthisis. The pupil of the affected eye did not act directly to light, but contracted on illuminating the other eye; with moderate pressure there was no sensation of phosphenes. The next day vision had improved, and she could distinguish large objects in a small peripheral portion of temporal half of field. Ophthalmoscopic examination showed the optic disc blanched, the arteries very much reduced in size but not filiform, the veins full and distinct. Round the optic disc and in the neighbourhood of the macula lutea a perceptible haziness of the retina was visible, but there were no hæmorrhages. The fundus of the other eye was quite healthy. On Feb. 5th the retinal haze was very much more marked and of a white cloudy appearance, quite concealing the margin of the disc; at the yellow spot a cherry-coloured spot, slightly oval in shape (transversely) and very clearly defined, stood out in marked contrast to the surrounding œdema. This patient was seen again about six months after. The ophthalmoscopic appearances were those of atrophy; the arteries were very small, but not obliterated. Vision the same as before. Mr. Deighton insisted upon the importance of being able to distinguish between thrombosis and embolism.

Mr. CARVER showed a specimen of Flat Foot taken post mortem from a young man, aged about thirty, who had followed the occupation of billiard-marker for some years. He remarked that after dissection of the parts the deformity appeared to be due, not to stretching or lengthening of the calcaneo-scaphoid ligament, but rather to displacement of the scaphoid and astragalus downwards and inwards, the head of the latter resting upon the anterior portion of the internal lateral ligament of the ankle-joint, and not on the calcaneo-scaphoid.

MIDLAND MEDICAL SOCIETY.

Mollities Ossium.—Foreign Body in the Œsophagus.—Epithelioma.—Hydronephrosis.—Wrist-drop.

AT the meeting on Dec. 9th, 1885, Dr. Holmes Joy in the chair,

Mr. AUGUSTUS CLAY showed the sternum, portions of the femurs, clavicles, and a part of the ilium from a case of Mollities Ossium in a woman aged thirty-nine, who had been under the care of Mr. Pearse, of Brierley Hill. She was by occupation a dressmaker, and her mother, sister, brother, and eldest son died of phthisis; she was the mother of five children, the last confinement being a difficult one. Her illness extended over nine years, and at the time of her death the bones of both thighs and legs were fractured, none of them showing any tendency to unite.

Mr. BENNETT MAY showed a child, aged seven years, from whom he had removed, by œsophagotomy, a halfpenny which had been swallowed three years and a half before the operation; it had ulcerated through the œsophagus and opened the right bronchus, and was lying partly in the œsophagus and partly in the bronchus. Its removal was easily effected: the child was at first fed by nutrient enemata in order to avoid the possible entrance of food into the bronchus or surrounding cellular tissues. At the present time there is a slight constriction at the seat of ulceration, but a bougie can be passed without any difficulty, and food is easily swallowed.

Mr. JORDAN LLOYD showed the whole of an Epitheliomatous Tongue and Submaxillary Lymphatic Glands, which he had removed from a man by Kocher's method, after temporarily ligating the tongue at its root in two separate halves. The operation was practically bloodless. The man died on the tenth day from exhaustion. Mr. Lloyd also showed a Kidney with Dilated Pelvis as large as a fœtal head, which he had successfully removed from a boy five years of age. Intermitting hydronephrosis, accompanied by great pain and constitutional disturbance, were the indications for removal. The operation was lumbar, and seven or eight renal arteries were ligatured separately, the kidney liberated with its pelvis unopened, and cut off through healthy ureter. The condition was probably congenital and depending on a unilateral kink. The boy is now in perfect health.

Dr. SUCKLING showed a man, aged thirty-five, who was suffering from wrist-drop, due to progressive muscular atrophy. There was complete paralysis and atrophy of the extensor muscles of both forearms, the supinator longus on each side escaping. Other muscles of the hand and front of the forearm were also affected. The paresis and atrophy had gradually supervened and advanced together. There was no history of lead-poisoning and no hereditary syphilis, but he had acquired syphilis four years previously. There was no response to faradaism or galvanism of the muscles of the back of each forearm. Elsewhere there were no qualitative changes.

Dr. FOXWELL showed a man with atrophy of the extensor muscles of both forearms and the short muscles of the hands, whose symptoms did not fully agree with any recognised form of such lesion.

Dr. SIMON showed a case of Aphasia, in which the power of writing was retained.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Treatment of Congenital Talipes Equino-varus.

AT the meeting of this Society on Dec. 4th, Mr. J. White, President,

Dr. LEWIS W. MARSHALL read a paper on the Treatment of Congenital Talipes Equino-varus. The author called attention to the unsatisfactory condition which existed in reference to the treatment of this congenital deformity. Quotations were given from recent papers published in the various journals, illustrating the want of unanimity between the opinions of surgeons. A brief summary of the method advocated by Mr. Barwell without division of tendons, and an account of the imperfect success obtained by Dr. Marshall, if slight cases be excepted, was read. Also the most recent pathological opinions as expressed in the joint paper of Messrs. Parker and Shattock at the Pathological Society in May, 1884, were touched on. Dr. Marshall stated that he concurred in the views contained therein, and believed in the mechanical production of this malformation. The fact of the males to females being in the ratio of 4 to 1 in his list of cases was thought possibly to be an additional argument in favour of Cruveilhier's theory, because of the usually smaller size of the female offspring. Intra-uterine pressure would therefore be less easily effected. The opinion as to most children having at birth a tendency to varus was also concurred in. Stress was laid upon the fact that the majority of congenital cases are due to paralysis of the peronei, together with displacement and altered relationship of the tarsal bones. The annotation published in THE LANCET a year or two ago, summing up the treatment of talipes equino-varus by plaster-of-Paris, was freely criticised, and an adverse opinion expressed. Dr. Marshall confined the use of this splint to the time anterior to the eleventh month, the period at which he preferred to divide the tendo Achillis. This limited use even was thought to be prejudicial. Mr. Davy's cuboid operation on infants was also objected to, and a case of Mr. Davy's was shown in which one foot had been treated by this method, and the other by division of the tendo Achillis by Dr. Marshall, and subsequent treatment by Mr. Barwell's springs. Dr. Marshall said that he adopted the following system: First, division of the tendo Achillis only at the eleventh month—i.e., at or about the time of walking; secondly, ten days after division Mr. Barwell's springs were applied; thirdly, a removable splint on the same lines was adopted; fourthly and finally, shampooing, faradisation, and exercises by Ling's system as advocated by Dr. Roth were used. Cases and photographs were shown, supporting the assertion that perfect and good results could be as easily obtained in this way as by any other. It was pointed out that no other tendon had been divided in any single case, nor was it believed ever to be necessary. The received doctrine that tendons should be cut in the front of the foot first was deemed to be wrong, because inversion of the foot was clearly obtained after excessive contraction of the calf muscles, and division of the tendo Achillis released this in part. The main points of difference between the method recommended by Dr. Marshall and that of orthopædists generally are included under the following heads: 1. Time of operation. 2. Tendons to be cut, and the order of doing this. 3. The apparatus used for after-treatment.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Epithelioma of Tongue.—Trephining for Traumatic Epilepsy.—Supra-pubic operation for removal of large Calculus.

THE second monthly meeting of the session was held in the library of the Newcastle-on-Tyne Infirmary on Nov. 12th, 1885, Dr. Fielden, President, in the chair.

Dr. MORISON showed a patient upon whom he had operated four years ago for epithelioma of the tongue and floor of the mouth. The man was sixty years of age at the time of operation, and the growth had invaded the front half of the tongue, the floor of the mouth, and was adherent behind the symphysis of the lower jaw. Two inches and a half of the lower jaw, the floor of the mouth, and the anterior half of the tongue were removed. The patient made a good recovery and had since done well, having a fairly useful jaw and powers of speech.

Mr. PAGE exhibited a boy nine years of age, whose knee he had excised a year ago. The boy, although so young, had now a useful limb, which appeared to be growing with his growth. Mr. Page also exhibited a patient whose femoral he had tied for popliteal aneurysm. The result was in every way satisfactory, the wound having healed by first intention, and the aneurismal sac could be felt in the popliteal space contracted and pulseless.

Dr. OLIVER showed a boy who had been trephined in the right parietal region for supposed traumatic epilepsy. The fits had developed after a blow on the head, and although on admission to the infirmary no injury to skin or bone could be detected, it was decided to trephine, as the epileptic phenomena were unilateral. The opening was made an inch above and behind the right ear, and a quantity of effused serum and lymph removed. The wound healed up well, but the fits continued, though with less severity and frequency. There had been no subsequent bulging at the seat of the operation.

Dr. MORISON exhibited a portion of Bowel with Perforating Ulcer and a portion of Intussuscepted Bowel, removed by abdominal section; also a series of seventeen Vesical Calculi, and considerable interest attached to this exhibit since it included the largest stone ever removed during life. This calculus, which weighs 1 lb. 6½ oz., was removed from a sailor, fifty-two years of age, who had suffered for thirty-eight years from pain and difficulty on micturition. The lateral operation was first tried, but it was found impossible, for want of room, to remove the stone in that way. A supra-pubic incision was then made, and as no lithotomy forceps which the operator possessed were large enough to grasp the stone, recourse was had to a pair of midwifery forceps, and the stone successfully removed. The man did well till the twelfth day after the operation, when, without warning, he suddenly became very ill, and died on the fourteenth day. No post-mortem was allowed.

Mr. PAGE showed the Sigmoid Flexure and Rectum from a patient who had suffered from fibrous stricture of the rectum. The stricture, which only admitted a probe, was at the juncture of the sigmoid flexure and rectum, and no fæces had been passed for fourteen days before operating. Right colotomy was performed, with complete relief of symptoms; but the patient died three weeks afterwards, and the post-mortem discovered extensive disease of the kidneys and partial occlusion of both ureters by cicatricial bands.

Dr. OLIVER exhibited a specimen of Aortic Aneurysm. The sac, which was of immense size, arose from the ascending aorta and projected forward between the pleuræ to the anterior chest wall, where it opened into a blood space behind the right pectoral muscles.

Dr. HUME read an interesting paper on two cases of Scirrhus of the Mamma, with Eczema of the Nipple. After carefully tracing the connexion between the two, the author came to the conclusion that where there was true eczema of the nipple—that is, eczema confined to the nipple alone—one was justified in recommending excision of the breast as a safeguard against the malignant disease which, in his opinion, was almost certain to follow in the gland.—The discussion was carried on by Drs. Drummond, Arnison, and [illegible], and Mr. Page.

Reviews and Notices of Books.

The Principles and Practice of Medicine. By the late CHARLES HILTON FAGGE, M.D., F.R.C.P. Two Vols. London: J. and A. Churchill. 1886.

[SECOND NOTICE.]

THE diseases of the Nervous System form a large part of the first volume, and their consideration is richly illustrated by facts of the author's personal observation. He discusses peripheral affections first—namely, paralysis and neuralgiæ,—and then passes to diseases of the spinal cord. The symptom of paraplegia serves as an introduction to this latter subject; it includes an interesting account of reflex movements, in which, however, the subject of the so-called "tendon-reflex" does not receive such attention as its significance merits. It must be remembered, however, that the study of these phenomena is very recent, and their explanation yet undetermined. After dealing with the pathology and symptoms of myelitis, various conditions are described which are hardly to be diagnosed from it—some of which, indeed, as spinal anæmia and hyperæmia, may have no real existence, or at any rate be unrevealed by symptoms. Reflex paraplegia, again, is discarded, the opinion being that a myelitis is present in most of the cases so assigned. Acute ascending paralysis is given from Erb's description, and we are told that no case of this remarkable affection could be found by the author in the records of Guy's Hospital. Alcoholic paraplegia receives but scanty notice, the wider extension of the subject at the hands of Lancereaux, Broadbent, and others, being again a matter which is one of our most recent additions to knowledge. As regards syphilitic paraplegia, the suggestion is made that it mostly depends upon defective nutrition of the cord from interference with blood-supply due to arterial disease, comparable to the affection which underlies so many cases of cerebral syphilis. Pursuing our glance through these pages, which teem with facts and are full of interest, we may note that Dr. Fagge believes the symptoms of "spinal irritation" to be explained by neuralgia of the posterior branches of the spinal nerves; that he describes in detail the subject of compression paraplegia, as illustrated in cases of Pott's disease, malignant disease of the spine, erosion by aneurysm (the rarity of compression from this cause being noted), by hydatid tumour and tumours of the membranes, examples of which are given from his own experience; again, in spastic paraplegia—which, although admitting the fact of lateral sclerosis in many cases, he thinks is often comparable to other spasmodic functional neuroses—he gives details of cases cured by the administration of Calabar bean. Under the head of Spinal Paralysis attended with wasting of muscles, he describes in turn acute atrophic paralysis (of infants and adults), chronic diffused atrophic paralysis, progressive muscular atrophy (more limited in its distribution than the preceding), bulbar paralysis, lead palsy, and pseudo-hypertrophic paralysis. This grouping of affections shows that in his view the latter two diseases own a centric origin, although the evidence is for the most part still wanting to determine the fact. Dr. Fagge indeed would assign a larger share to the action of lead poisoning than many admit, believing that some cases eventuate in more or less generalised muscular atrophy, distinguishable from progressive muscular atrophy only by the electrical test. Locomotor ataxy and disseminated sclerosis are respectively dealt with in separate sections.

The chapter on Diseases of the Brain opens with a discussion of hemiplegia and aphasia. It is of interest to learn that in a paper read before the Guy's Hospital Physical Society in 1860 or 1861 Dr. Fagge anticipated the conclusions formulated subsequently by Dr. Broad-

Digitized by Google

bent regarding the exemption of harmonious movements from paralysis in hemiplegia; and the following remarks, giving an explanation of the varying distribution of paralysis in cerebral hemiplegia, has been fairly substantiated by the recent researches of Horsley. Dr. Fagge says (p. 488), speaking of the views of Jackson and Ferrier: "But, in spite of these high authorities, I cannot help thinking it is possible that, at least in the internal capsule, the fibres which belong to the upper limb may hereafter be distinguished from those that pass to the lower limb. We shall hereafter see that Hitzig and Ferrier state that the cortical centre for the leg muscles lies nearer the median plane than that for the arm muscles. It seems to me a fair inference that if there be a distinction of fibres within the internal capsule, those for the leg should be situated further inwards (or forwards) than those for the arm." And he goes on to point out that in cerebral hæmorrhage the outer and hinder part of the capsule is often alone lacerated. The subject of cerebral hæmorrhage abounds in details of clinical and pathological experiences. Two cases of an extremely rare condition—chronic diffused cerebritis—are recorded; hydrocephalus is attributed to a chronic inflammation of the ependyma and choroid plexus; atrophy of the brain is illustrated by "general paralysis of the insane"; and the various forms of meningitis, thrombosis of sinuses, and hæmatoma of the dura mater conclude the chapters devoted to organic disease. The interesting subject of the neuroses follows, dealing first with the *spasmodic*—viz., spasmodic tic, torticollis, paralysis agitans, chorea, tetany, tetanus, and hydrophobia; and then the *paroxysmal*—migraine, epilepsy, paroxysmal vertigo, and paroxysmal insanity; the subjects of hysteria and hypochondriasis being dealt with apart, and forming, as it were, a link to the section upon Psychoses, in which the various forms of insanity are dealt with. Lastly, the consideration of the diseases due to poisons and to heat conclude the subject of nervous disease, which have seldom received so ample and exhaustive a study in any similar text-book.

The remainder of the first volume is devoted to the Diseases of the Respiratory Organs. The affections of the larynx are detailed as fully as is consistent with a general treatise, and amongst other indications of the author's acquaintance with recent teachings may be cited his references to Dr. Semon's work upon abductor paralysis. There is a very full discussion upon Croup, a term which is retained by Dr. Fagge in its old significance, whilst he expresses in detail the facts which have led him to adopt what may be called the old-fashioned doctrine as to the nature of the affection. To be sure, he admits the practical impossibility on anatomical grounds of discriminating between simple membranous croup and laryngeal diphtheria, but he thinks the evidence goes to show that it is only exceptional for diphtheria to be limited to the air-passages, and wholly rejects the notion that the presence of exudation on the pharynx is sufficient to determine the diagnosis in favour of diphtheria; for he deems it probable that a non-specific membranous inflammation may extend upwards to the pharynx. In spite of the ingenuity of his reasoning, and the force of many of his arguments, the hypothesis of a specific poison being at the root of all cases of (non-traumatic) membranous laryngitis seems to best accord with facts, but at the same time there is room for further investigation, which Dr. Fagge's utterances may serve to stimulate. The general symptomatology of Chest Diseases, including the methods of physical diagnosis, introduces the articles devoted to their consideration. We note that the author adopts a cautious line in dealing with the etiology of acute pneumonia, and there is not of course any reference to Friedländer's discovery of a specific micrococcus. Still, Jürgensen's doctrines receive full attention, and it is pointed out that all inflammation must be regarded as due to some specific exciting cause. Laennec's division of gangrene of the lung into circumscribed and diffuse is held to be untenable in the light of extended experience in the post-mortem room. The question of surgical treatment of gangrenous cavities is another of those subjects, which has almost arisen since Dr. Fagge wrote; at any rate, no mention is made of it. There is a very elaborate review of the etiological conditions bearing upon pulmonary phthisis, and the influence of soil, climate, and hygienic surroundings is shown to be very great in determining the disease, whereas the theory of contagion receives but little countenance. Neither does Dr. Fagge admit that in inheritance there is more than a transmitted "vulnerability"; and he rejects the doctrine of "phthisis ab hæmoptæ."

The second volume opens with Diseases of the Heart and Bloodvessels, some sections of which—viz., Valvular Disease of the Heart, Aneurysm, Thrombosis, and Embolism—have been supplied by Dr. Wilks, these being subjects which the author had left unwritten. It may be remembered that Dr. Fagge contributed an article on the first-named of these subjects to "Reynolds' System." It is needless to say that Dr. Wilks discusses them with the clearness and precision which characterise his writings. Reverting to Dr. Fagge's own work, we may mention that he discusses admirably the etiology of dilatation and hypertrophy of the heart, and shows clearly how often these may give rise to valvular incompetence. We find the subject of mediastinal tumours interpolated in the chapter upon Diseases of the Bloodvessels, probably from the clinical resemblances between them and thoracic aneurysm. Diseases of the Stomach are introduced by a chapter devoted to the subject of Dyspepsia, the author showing an intimate acquaintance with the views of the leading authorities upon this common but inadequately understood derangement. In dealing with Gastric Ulcer, he discusses Virchow's long-accepted view of its production by local ischæmia, but does not offer an alternative hypothesis. The Diseases of the Intestines include two subjects with which Dr. Fagge's name is always associated—viz., lead colic and intestinal obstruction; and their discussion in this volume shows evidence of his vigorous and independent thought. In speaking of acute peritonitis, he is very sceptical as to its ever (or with extreme rarity) occurring idiopathically, contending that a primary local inflammation in neighbouring organs or regions is almost essential to its supervention. The Functional Derangements of the Liver are dealt with much in the broad sense which Murchison gave them; and the subject of Jaundice serves as a centre around which hepatic disorders are grouped. It is pointed out that "simple jaundice" is by no means always catarrhal; and a contrast is drawn between acute yellow atrophy and febrile jaundice—the latter almost as fatal as the former, but evincing a variety of causes, amongst which "pylephlebitis" is the most prominent local affection. Other causes of jaundice—as gall-stones, cancer, &c., are reviewed; and, after discussing the subject of bile-formation, Dr. Fagge concludes that it is hardly possible to formulate a theory of jaundice other than that bile-pigment is first secreted and then reabsorbed—endeavouring thus to break down the distinctions between "hæmatogenous" and "hepatogenous" jaundice. He seems to make rather a subtle distinction between the "secretion" and the "production" of bile; but we are grateful for the manner in which he brings his knowledge to bear upon the question. In the section upon Cirrhosis of the Liver, as in that upon Jaundice, one is surprised at the absence of any specific mention of so-called hypertrophic or biliary cirrhosis (except in a brief footnote by the editor); but it is interesting in this connexion to note that, according to Dr. Fagge's experience, in most cases of cirrhosis of the liver accompanied by jaundice the liver has been enlarged, often greatly so, and mostly containing

Digitized by Google

much fat. Abscess of the liver he inclines to view as being mostly, if not invariably, secondary to dysentery. A chapter is devoted to Painless Enlargements of the Liver, and the section upon Hydatid Tumours is, as may be expected, written from a wide personal knowledge. Leuchæmia and Hodgkin's Disease are next discussed, and then we pass to the subject of Diseases of the Urinary Organs. Among functional derangements are considered diabetes insipidus—a rare affection, according to the author—and renal inadequacy; then the changes in the composition of the urine are discussed, followed by an admirable account of hæmoglobinuria. Of the paroxysmal affection that goes by this name we are told that it is now well ascertained to be due to disintegration of the red corpuscles within the blood, but the difficulties attending its pathology are fully recognised. Another subject, treated at greater length than commonly in text-books, is hydronephrosis. The pathology of diabetes receives considerable attention, and the opinion is expressed that excessive formation of glycogen is the most tenable of all hypotheses advanced to explain this disease, but at the same time little stress is laid on the theory that the hepatic derangement is itself due to a medullary lesion. In fact, Dr. Fagge hardly seems to have done justice to physiological research upon this question; nor is the subject of diabetic coma given as much attention as it merits. Dr. Fagge recognises five forms of Bright's disease—viz., parenchymatous nephritis, lardaceous disease, cirrhosis, consecutive Bright's disease, and cystic disease,—and devotes several pages to their common symptomatology. Of all the topics raised in this instructive chapter we can only refer to his views respecting the cardio-vascular changes in chronic Bright's disease and upon uræmia. The former are, he thinks, to be referred to primary renal derangement, and he harmonises Mahomed's views by the suggestion that such derangement, sufficient to cause a heightening of arterial pressure, may be functional, or at any rate may not require the structural lesions which mostly characterise it. The theories concerning uræmia are subjected to lengthy criticism, but without any clear solution being arrived at, as may be gathered from the following paragraph (p. 459): "In conclusion, there seems to be no doubt that uræmia is produced by the poisonous action upon the nervous centres of materials accumulated in the blood as the result of defective excretion by the kidneys. But it is still uncertain whether this action is excited by one substance in particular, or by all of them together. In many cases the actual outbreak of convulsions is immediately due to some cardiac disturbance of the balance of the bodily functions, which may then be supposed to have been previously unstable." ..... Sometimes, perhaps, what directly causes uræmic symptoms is the sudden failure of the heart to keep up an active circulation through the renal vessels, so that the excretory function of the kidneys, which may for a long time have been more or less impaired, now becomes rapidly altogether ineffectual." The symptoms of Addison's disease are referred to derangement of the sympathetic, from which conclusion Dr. Fagge does not see any escape; although it [illegible] at least so far as concerns the cutaneous pigmentation, the acceptance of more than one hypothesis. Gout, [illegible], arthritis deformans, and gonorrhœal synovitis are the subjects next dealt with, to which the editor has appended a few paragraphs on Charcot's joint disease; then [illegible] and mollities ossium; and lastly, diseases of [illegible] atrophy, anæmia, hæmophilia, and purpura.

[illegible] all that the author had prepared for publication [illegible] death; but, in fulfilment of the original design, [illegible] Dr. Pye-Smith, has supplied the chapters upon [illegible] of the Skin. Comprising upwards of one hundred [illegible] chapters form a valuable part of the work, especially as the subject is dealt with in a manner which is much to be admired. Rejecting all attempts at a "natural" classification as useless, and condemning the binomial nomenclature as "pedantic, cumbrous, and barbarous," Dr. Pye-Smith first defines the various "elementary lesions" characterising cutaneous disease, the distribution of the lesion, and the circumstances attending the case. He then deals with the diseases in the following order: Eczema and common superficial dermatitis, papular forms of common dermatitis, pityriasis rubra, psoriasis, pemphigus, scabies, erythema, disorders of sebaceous glands, hair-sacs, and sweat glands, ringworm and its allies, with other affections of the hair, chronic deep inflammations and hypertrophies, lupus, leprosy, tumours of the skin, pigmentary, hæmorrhagic, and neurotic affections, concluding with some practical remarks on classification and diagnosis. It would be impossible to do justice to the writer by attempting an analysis of these chapters; it must suffice to say that he has done much to place dermatology on a scientific basis by this monograph, and that he has admirably filled the place of the author of the work. It is not for this contribution alone that the reader is indebted to Dr. Pye-Smith. He has had the sole responsibility of arranging and editing the manuscripts of this work for publication, and we can imagine that he has willingly devoted much time to this really formidable task; for although of necessity the rapid progress of medical investigation renders it almost impossible for a work such as this to comprise all the most recent advances in knowledge, much can be done by the assiduous supervision of a careful editor to supply such deficiencies. This Dr. Pye-Smith has done with conscientious regard to the author's work, and the result is a treatise which may be claimed to be among the most scholarly and scientific works upon medicine, and one which is deserving of the most careful study.

Descriptive Catalogue of the Pathological Specimens contained in the Museum of the Royal College of Surgeons of England. Second Edition. By Sir JAMES PAGET, Bart., with the assistance of JAMES FREDERICK GOODHART, M.D., and ALBAN H. S. DORAN. Volume IV. London: Printed for the College, and sold by J. and A. Churchill. 1885.

WE are glad to see that another volume of the new catalogue of the Hunterian Museum has been issued from the press. The fourth volume shows the same signs of careful work as characterise its predecessors. To recatalogue such a large collection of valuable specimens was a great task, but its accomplishment will add enormously to the value of the Museum. In this volume the specimens numbered 3514 to 4880 are described. They illustrate morbid conditions of the Urinary Organs, of the Nervous System and Organs of Special Senses, of the Generative Organs and Breast, and the Anatomy of Stumps. This volume therefore deals with matters of wide interest and importance.

AMBULANCE WORK IN BURMAH.—A class for the Volunteer Artillery at the Rangoon branch of the St. John Ambulance Association, instructed by Dr. T. F. Pedley, medical officer of the corps, has been examined by the Bishop of Rangoon, who holds the degree of Doctor of Medicine, and twelve members have been reported to St. John's Gate as entitled to certificates. The male classes held last year at Rangoon have recently been re-examined, and the Bishop is now instructing a large class of ladies, wives of officials, merchants, and others.

SUDDEN DEATH.—On the 2nd inst. Mr. W. J. J. Scofield, M.R.C.S., died suddenly at his residence in Bath. Mr. Scofield, who at the time of his decease was in his fifty-seventh year, had been in practice for some twenty years in Birmingham, and had retired and settled in Bath only about two years ago.

THE LANCET.

LONDON: SATURDAY, JANUARY 9, 1886.

IN a recent article on operations undertaken for the relief of patients afflicted with cancer of the œsophagus and of the stomach, we referred to the fact that doubt was sometimes expressed as to the justification of performing such serious operations on the subjects of incurable malignant disease. We were unable then to discuss this question, but it is one of so much moment that it is worth while to see what are the principles which should guide the surgeon when this problem is presented to him. It is essential to recognise from the outset the fact that the conditions of this problem may and do vary within very wide limits, at each extreme of which the right line of practice would be quite evident to any surgeon called upon to operate.

A great risk and a severe operation are only justifiable when the advantage to be gained is also great. Where, for example, an operation promises complete cure or long immunity from an otherwise certainly fatal malady, it is obviously right to undertake it, even if it be severe and dangerous. This is a somewhat self-evident proposition, and yet one of its applications to practice is often lost sight of. Experience has fully shown that, other things being equal, the success of excisions of malignant growths is largely dependent upon the period at which they are performed. As, therefore, an early operation for cancer offers a far greater prospect of long immunity from recurrence than a later one, a wider and more severe operation is justified in the earlier rather than the later stage. The contrary view is sometimes acted upon, even when not actually stated. Excisions of limited extent are often practised when malignant tumours are small, and because they are small and of recent origin; while in tumours of greater age and more extensive growth more formidable operations are readily undertaken, in spite of the small prospect of success they hold out. The converse should be the rule. When the surgeon has to deal with a case in which a free excision holds out a strong hope of long immunity or even of cure, a very thorough operation should be performed, even although it cause some deformity or mutilation, or expose the patient's life to danger. The great advantage to be expected from such an operation justifies the greater severity and the extra risk of such a procedure. Where the object aimed at is the removal of a malignant tumour, with the view of interrupting for a time, or stopping for ever, its growth, this principle should be kept in view, and if it were fully carried out in the early operations we believe the practice would be attended with most favourable results.

But this is not the only object for which operations are performed in patients suffering from malignant disease. Some are undertaken to promote comfort, even where there is no hope of removing the disease entirely. Thus it will afford considerable temporary relief to a patient's distress to excise an offensive fungating tumour of the breast or a painful mass of cancer in the mouth, even when there is no prospect of the operation eradicating the local disease. In such a case the surgeon should limit his procedures within narrow bounds, aiming to attain his end with the minimum of risk, and he should not be led to extend his operation to a wider range in the delusive hope of attaining some further good, simply because he is induced to operate at all to promote the patient's comfort. There is a temptation to argue thus: "Since an operation is justifiable or rendered necessary by the extreme local distress which is occasioned by the presence of the tumour, and which can be at any rate temporarily relieved by operative procedure, why not make it as wide as possible on the chance of delaying the recurrence for a long period?" The very condition for which the operation is undertaken renders illusory any such hope, and the surgeon should not be misled by a sophistry of this kind,, but should carefully regulate the severity of his procedure in any given case by the prospect of good to be attained.

The operation of colotomy for malignant disease of the rectum or sigmoid flexure affords another important illustration of a similar ethical principle. The relief that this operation affords is very marked; and there is every reason to believe that diverting the course of the fæces not only removes a source of pain, but lessens the rapidity with which the tumour grows and its subsequent ulceration. Hence, colotomy does not become more justifiable, but less so, in the later stages of the disease, when all the good it holds out is the relief of obstruction. When obstruction is complete the operation becomes very *urgent;* but the benefit it affords is at the best small, as compared with an earlier one, which may be effectual not only to prevent obstruction, but to relieve pain and retard growth. Too often this operation is postponed until the final stage of the disease, when the patient's powers are exhausted, and any procedure — even the simplest—has special peril; even then it may be justifiable. But it is bad surgery to postpone to a time when it is nearly valueless an operation which, undertaken earlier, is capable of affording great benefit.

In conclusion, we must allude to one or two views that are sometimes expressed in regard to such operations. It is said by some that where the surgeon is unable to afford complete or great relief, and especially where he is unable to remove the disease, he should not undertake any operation at all, for at best it only prolongs a miserable existence. In reference to this, it must be borne in mind that with universal consent surgeons have agreed to regard life as sacred, and its maintenance as the chief aim of their art. When once the quality of the life in point is allowed to be placed in one scale or the other, an element of confusion is introduced, and the surgeon in stepping out of his province assumes a responsibility that is not his. He must never allow himself to argue that life is not worth preserving or prolonging; to do so is always wrong and often dangerous, although the course of action it would indicate may be, for other reasons, in some cases the right one. Similarly, it is false to argue that because a patient is the subject of an incurable disease, or suffering severely, the fatal termination of an operation is any the less regrettable. *Fiat experimentum in corpore vili* is sometimes quoted as the justification for such a view;

Out of a list of, ... patients, twenty-five or thirty would be cases ... in some form or other—conjunctival, nasal, ... bronchial, gastric, gastro-intestinal, hepatic, ...nal or vesical. In one or two he is pretty sure ...d very high temperatures, varying from 100° ...h or without a defined pneumonia. Most family ...n will have been struck by the apparent infec- ...tious catarrhs, extending often through nearly ... of eight or ten children, affecting them with ...rious of intensity. They seem to be interminable ... whether as regards the persistence of the catarrh in individual cases or the succession of cases. One of the best remedies, by the way, in such cases is quinine, taken two or three times a day. Even young children will take this remedy well, and it will often pull them together and bring back normal temperatures more quickly than any other remedy. Perhaps this is especially so when pallor or perspirations accompany or alternate with the high temperature. The apyretic action of quinine will often be very striking. The drug may either be given in repeated doses during the day, or, when the night temperature is high, in one good dose at night. It is a curious novelty to see practitioners ordering quinine in cases where their predecessors would have prescribed James's powder. But the practice has much to recommend it, especially in certain families, where there seems almost an epidemic influence at work, and saline and expectant treatment fails to make any impression. One of the most troublesome forms of catarrh in the damp and foggy weather of the present Christmas-time has been the tonsillitic,—generally follicular in character, sometimes suppurative, but in some districts, especially of the metropolis, with a suspiciously diphtheritic appearance, affecting numbers in the same house, with marked prostration of strength, and perhaps slight albuminuria. It may well put London practitioners on their guard to learn from the Registrar-General that of twenty-four deaths from diphtheria in twenty-eight of the large towns of England in the week ending Dec. 26th, fourteen occurred in the metropolis. The fact suggests disinfecting measures and applications in all throat cases of a suspicious character.

Though disease has not been so fatal in its character as in severe weather it is apt to be, giving another contradiction to the well-refuted saying that "A green yule makes a fat churchyard," it has been considerable in amount and depressing and debilitating in character. Those happy mortals who can escape from our "fickle" climate, and go where the sun is seen to shine occasionally, and where the air is not laden with soot and fog, are to be congratulated; for those who cannot, medicine must be chiefly protective, strength must be preserved, sleep must be cultivated, fatigue and late hours avoided. The comfortlessness of the world without must be counteracted by genial light and warmth within, and by more clothing, and the disease, which may still appear in spite of our well-directed advice, must be met, as we have suggested, by measures that sustain the strength while rebuking fever.

WHENEVER Mr. HORSLEY undertakes to provide a course of lectures bearing on pathology, it is perfectly certain that his audience will not have to listen to lengthy dissertations on minute and comparatively uninteresting points. In the short course which he delivered in December at the University of London subjects of much importance and wide extent occupied the five lectures which have to be given agreeably to the clauses of the late Mr. BROWN'S will. In the last and present number of THE LANCET will be found full abstracts of the lectures, and we propose here to select the most important matters brought forward, and endeavour to submit them to whatever criticism they may seem to deserve.

Last year Mr. HORSLEY extirpated the thyroid gland of

Digitized by Google

monkeys and dogs, and obtained results which led him to the conclusion that this organ exercises very important metabolic functions. He believes that the thyroid in some way transforms mucinoid substances so as to make them available for further purposes in the economy, and he also produces evidence to show that the perfect formation of the blood is furthered by the presence of the same organ. It need hardly be said that Mr. HORSLEY was not the first to extirpate the thyroid gland from animals, nor was he the first to show that the symptoms thereby resulting belonged to the same category as those of myxœdema, cretinism, and cachexia strumipriva. But it was his chief care to prove that the loss of the thyroid was the *causa causans* of the symptoms, and that the likeness of artificial myxœdema to the other diseases just mentioned was something more than a mere similitude, and in fact amounted to more or less identity, only incomplete because of certain conditioning elements of time and space and other avoidable circumstances.

If the gland be slowly destroyed by a chronic sclerosing process leading to gradual disappearance of the working tissue, then we have myxœdema lasting a corresponding length of time, and manifesting a suitable group of symptoms. Rapid removal of an organ cannot be expected to give us the same order of symptoms as its slow destruction, and the more recent experiments of Mr. HORSLEY must prove of great value in the endeavour to bridge over certain gaps which, though of necessary theoretical existence, cannot, nevertheless, be disregarded, and may legitimately be pointed out by those who find themselves unable to admit identity unless on the clearest of evidence. Is the disease that follows removal of the thyroid in animals essentially the same disease as that known as myxœdema in man? If it be, cannot we by some means so manage to lengthen out the inevitably compressed disease, and so give the semblance a still greater likeness? This question appears to have been answered affirmatively by Mr. HORSLEY'S recent experiments. He has found that monkeys which have been deprived of their thyroids can be kept alive for from four to six months by the employment of artificial heat. (*Vide* Lecture I., page 4 of THE LANCET.) This method not only prolongs the duration of life, but alters the mode of onset of the symptoms, and indeed tends to cause the disappearance of some of the symptoms of the early stages. It would be of much interest if it could be shown that a slowly induced artificial destruction of the thyroid in monkeys gave an even more perfect resemblance between artificial and human myxœdema. Is it not possible for an experimental pathologist to set up a chronic sclerosing process in the thyroid gland by means of a slow form of irritation such as that caused by setons, or by some other kind of continuous irritation? In contemplating the resemblances between the natural and the experimental diseases, allowance must be made for differences of constitution and for the time of life at which the removal takes place. Age exercises a very important influence in both the experimental and natural disease, for it is found that young dogs and animals die rapidly with a sort of convulsive group of symptoms; and KOCHER'S results on man show that age also is a powerful element in the production of cachexia strumipriva.

Unexhausted as the subject yet is, this formed but a small part of the material that Mr. HORSLEY laid before his hearers. Questions of great weight in neurology occupied the chief part of his lectures. How endless is the practical study of the nervous system, what vast tracts lie unrevealed, what hidden depths unfathomed, not even the most accomplished neurologist could venture to assert. A superficial observer might think we had travelled a long way in the discovery that there is an excitable zone in the cortex of man, monkeys, and other animals; but the thoughtful alone know the shallowness of the step thus made in advance. It is true here, as elsewhere, that one thing more uncovered but reveals larger numbers of undiscovered facts beneath.

Mr. HORSLEY has greatly interested himself in the subject of the mode of discharge of nervous energy from motor regions, and he, with SCHAEFER, has arrived at the interesting conclusion that motor nerve cells appear to have a regular rate of discharge of about eight per second. We know that the idea of a continuous liberation of energy is not yet rooted out, but the very notion of a *discharge* conveys the element of intermittency. But what an important discovery, supposing it to turn out every way true, that this intermittence has a regular rate, and that nervous explosions do not act capriciously—as indeed no one would expect them to do. Mr. HORSLEY tells us that he has measured the rate of the tremors of artificial myxœdema, of the spasms of canine chorea, of the tremors of paralysis agitans, of the movements of disseminated sclerosis, and finds that the above-mentioned rate holds good. And Dr. GOWERS some years ago showed that the rate of an ankle-clonus was eight per second.

Another and separate field of work treated by Mr. HORSLEY was the graphic record of muscular movements resulting from stimulation of the various parts of the motor path from the motor-cortical region to the nerves. The tracing obtained from stimulation of the "motor" cortex is of a striking character: the muscle passes first into the tetanic state after a decided period of latency; but the fall of tetanus is perhaps the most interesting part of the myogram; the gradual descent of the lever is seen to be interrupted by waves indicating clonic spasms, which have the not unexpected, but still remarkable, rate of eight per second. These clonic spasms may be observed for a variable time after the cessation of cortical stimulation. This kind of tracing is regarded as pathognomonic of cortical discharges, for the lecturer assured himself that such clonic spasms only appeared when the motor cortex was in existence, and could practically not be obtained when stimulation was made of any part of the motor path below the cortex. Having investigated the myograms obtained from stimulation of the various parts of the normal motor path, he compared them with the myograms resulting from stimulation of the motor paths in cases of tremors of artificial myxœdema and canine chorea, and differences were found in the way of increased excitability and more rapid exhaustion, for the details of which the abstracts must be consulted. The relations of the thyroid to the pituitary body has led him to attempt the removal of the latter. This hazardous operation has been done twice with success, and the dogs lived five and six months without manifesting any special symptoms referable to the loss. The subject of

Digitized by Google

canine chorea has been investigated with thoroughness, and MR. HORSLEY'S chief contention is that the symptoms are due to the existence of a disseminated sclerosis.

THE health of London in 1885, judged by the mortality statistics issued by the Registrar-General in his returns for the fifty-two weeks that ended on Saturday last, was unprecedentedly satisfactory. The death-rate during the year did not exceed 19·7 per 1000 of the estimated population of Registration London, exceeding four millions. This rate showed a further decline from the low rates in the preceding two years (20·5 and 20·3), which were lower than the rates in any previous year since the Registrar-General's returns were first issued in 1840. The reduction in the London death-rate has been continuous since 1860. In the five years ending 1865 the mean annual rate was 24·4, and in the following five years (including the cholera year 1866) it was 24·3; while in the two five-year periods of the following decade (1861-70) the rate successively fell to 22·9 and 22·0. In the last five years (1881-5) the fall was more remarkable, the mean rate declining to 20·6, and the rate in each of these years was lower than in any previous year on record, excepting only 1850, which followed the fatal cholera year, 1849. Independently of the death-rate from all causes, the mortality statistics for 1885 afford other and conclusive evidence of improving sanitary condition. The death-rate from the principal zymotic diseases did not exceed 2·3 per 1000, against 3·5, 2·8, and 3·4 in the preceding three years, and was lower than in any year on record. The deaths from measles showed a slight excess, but those from each of the other principal zymotic diseases were below the average. The most marked decline was shown in the deaths from scarlet fever and from enteric fever—the two diseases, it may be mentioned, other than small-pox, to the isolation and treatment of which the Metropolitan Asylum Hospitals are mainly devoted. The deaths from small-pox, which had been 430, 136, and 913 in the preceding three years, were 899 in 1885. Infant mortality, measured by the proportion of deaths under one year to registered births, was equal to 148 per 1000, corresponding with the average rate in the preceding three years, but showing a decline of 10 per 1000 from the mean rate in the ten years 1871-80. Neither in London, nor in England and Wales generally, has the rate of infant mortality shown so marked a decline in recent years as has the death-rate of children above one year of age.

AT the last meeting of the North Dublin guardians, Dr. Kenny, M.P., the medical attendant at the workhouse, applied for and obtained seven days' leave of absence in order that he might attend the opening of Parliament. We shall watch with interest the amount of success which attends the attempt to combine the functions of legislator and attendant to the Dublin Workhouse, where his presence is required every day, in one and the same individual. It appears to us that either St. Stephen's or the sick paupers will suffer.

THE Professorship of Anatomy at Dorpat vacated by Dr. Stieda, who has gone to Königsberg, is to be filled by Dr. August Rauber of Leipsig, who was formerly assistant to Rudinger and Bischoff in Munich, and afterwards prosector for His in Basle, whence he went to Leipsig as prosector, and was subsequently appointed Extraordinary Professor.

Annotations.

"Ne quid nimis."

THE CONTINUANCE OF CHOLERA IN SPAIN.

CHOLERA is stated to have broken out at Algeciras in the province of Cadiz, on the western side of the bay into which Gibraltar projects on the east, and also at Marbella in the province of Malaga, and which lies on the coast about midway between Gibraltar and the city of Malaga. The result is that quarantine has been established at Gibraltar against both the seaports in question. Some surprise is often felt at the ready imposition of quarantine by a British possession such as Gibraltar; but quite irrespective of the views which may be there held as to the desirability of imposing this restriction or not, it must be remembered that Gibraltar has practically no option in the matter, for if it did not impose quarantine on communications with the neighbouring places and countries where cholera is alleged to exist, all surrounding countries, including Spain, would put Gibraltar in quarantine; and so its means of existence and its food-supplies would be cut off. It is further rumoured that cholera still tends to recur in the neighbourhood of Brest.

The province of Malaga was severely tried during the epidemic last year; in spite of official denials, there were more than 400 deaths in the town of Malaga itself distinctly due to cholera. The Spanish port authorities, for political and commercial reasons, and in obedience to orders received from Madrid, gave clean bills of health to the ships leaving this port; but the English consul was compelled to contradict these certificates and notify the presence of cholera. Under such circumstances and as there are not English consuls in every part of Spain, it is difficult to know what is really taking place. But it nevertheless seems quite evident that the cholera is still lingering, at least in the south and south-west. It has ominously approached the frontiers of Portugal, notably at the Christine Islands, near Huelva; and the cases, occurring so late in the year, suggest the possibility, if not the probability, of a sharp revival in the spring. Last winter the cholera continued at Toledo late in the year, not sparing its victims even when the snow was lying some feet deep on the ground, and it only ceased to break out again with the commencement of the spring. In the province of Valencia, the cholera also began this year just where it had left off during the previous winter. Thus, Portugal, and those portions of Spain which have not yet been severely tried, may still have to undergo a severe visitation.

HUNTER'S HOUSE.

IT is sad to think that the house and grounds occupied by the great naturalist and surgeon, at Earl's-court, will ere long fall a prey to the unsparing hand of "civilisation." One by one the relics of the past, which serve to keep green the memory and the recollection of many a noble life, are allowed to become extinct, or are ruthlessly destroyed. The contemplation of Earl's-court house brings vividly to mind the scenes transacted there by its former owner. Here it was that the great Irish giant, Byrne, or O'Brian, was by a pious fraud on the part of Hunter saved from oblivion. Hunter, being desirous of obtaining the skeleton of O'Brian, bribed heavily the guardians of the body who had been commissioned to bury it in the sea, and in order to ensure success in his enterprise boldly submitted the disjointed cadaver to the seething cauldron. This episode in Hunter's career shows the dauntless courage, the pertinacity of purpose, and the ever-present desire of seeking after knowledge for its own sake, which were

Digitized by Google

pronounced traits in the great anatomist's character. It was at Earl's-court, too, that Hunter watched so carefully the habits and studied the instincts of animals kept in captivity, and made innumerable observations and experiments, of which we have an imperishable monument in Lincoln's-inn-fields. It is not only the medical profession, of which he was so distinguished an ornament, that gained by the researches of Hunter, for his life-work forms one of the brightest spots in our national history. It is to be hoped that, if the "dens" where John Hunter kept imprisoned his ferocious leopards and the copper in which the mortal remains of the Irish giant were subjected to fervent heat cannot be allowed to rest longer in the place they have hitherto occupied, at least some attempt will be made to find a fitting receptacle for their future preservation. Is it too much to ask the learned member for the University of London to give a brief respite from care to his laborious ants and turn his attention to the safeguarding of "an ancient monument"?

POISONING BY PHOSPHORUS AT WOOD GREEN.

ON Dec. 30th an adjourned inquest was held by Mr. G. Collier, deputy coroner for East Middlesex, at the Lordship Tavern, Lordship-lane, Wood Green, touching the death of a single young lady named Edith Hunt, aged twenty-two. The deceased was about six months advanced in pregnancy. According to the evidence of Sarah Jane Thompson, who was in the service of Miss Hunt, the latter did not manifest symptoms of serious illness until Dec. 18th, when she complained of headache and pain in the chest. On the 19th vomiting set in, and on that date deceased is alleged to have stated, "I took some poison on Thursday week, and I have taken phosphorus paste." Mr. Webb, surgeon, who was called in the same day, prescribed for the sickness, and on the morning he found her "again vomiting *blood* and unconscious, and almost pulseless." She never regained sensibility. At the post-mortem examination the stomach was observed to contain a small quantity of "dark fluid" like that vomited. The opening inquiry was adjourned for the testimony of Dr. Tidy, who had been entrusted with the analysis of the stomach and its contents and portions of the viscera. Dr. Tidy's evidence was to the effect that "the stomach and intestinal linings were healthy"—a statement rather surprising when taken in conjunction with the observation of Mr. Webb, that deceased had vomited blood on two days. The viscera showed excessive and extensive fatty degeneration. *Phosphorus* was absent, but this was accounted for by the supposition that it had been taken in small repeated doses and had become oxidised. Dr. Tidy unhesitatingly averred that death was due to phosphorus-poisoning; and the collateral evidence lends great weight to this view, inasmuch as the deceased is reported to have acknowledged taking some "paste," and an almost empty bottle of James's phosphorus paste was found in the dresser drawer, together with an unopened bottle of the same. We do not wholly dissent from the view taken by Dr. Tidy, that the symptoms and their course were determined by the drug having been taken in small repeated doses; at the same time, it appears not improbable that the vomiting of blood might very well be explained as a *late effect*, and that only one dose may have been taken, and that, too, many days prior to the fatal issue. The researches of Tardieu and others prove that there is no poison more capricious in its action than phosphorus, and that, although the effects may be roughly classified as irritant, nervous, and hæmorrhagic respectively, there are many instances in which they coincide and succeed one another. If Miss Hunt's assertion, that she took the paste on a certain date, can be relied upon, assuming the witness spoke the truth, there is an end of the matter, for it seems certain that after the dangerous symptoms began to develop no fresh dose was exhibited, or the chemical analysis would have succeeded in detecting traces of the element. But the jury by their verdict—"That deceased met her death by phosphorus-poisoning, but how administered there was no evidence to show"—distinctly ignored the statement of Thompson concerning the confession of deceased. Some painful social matters were disclosed during the inquiry, which, to say the least, in our opinion, fully justified the rider to the verdict, "that the case required further investigation." A coroner's court is a court of first instance, or preliminary inquiry, and its main function is to arrive at the cause of death. It is desirable, no doubt, that the "how, when, and by what means" should receive a satisfactory answer, but this often requires more time than is at the disposal of the court. The verdict of the jury is no bar to further investigation.

THE BISHOP OF LONDON ON JUVENILE TEMPERANCE.

THE Bishop of London, in addressing the metropolitan members of the United Kingdom Band of Hope, congratulated himself and his fellow-teetotallers on the numbers of children growing up in London on temperance principles. This is a good fact, upon which society is indeed to be congratulated. There are few subjects on which medical authorities are more agreed than in thinking that children are far better without any form of alcoholic stimulant, and juvenile education of this sort is the best counteractive of that deeply inherited vice of English children which is the result of what Dr. Valpy French calls in his interesting book "Nineteen Centuries of Drink in England." Recent Christmas Days have given painful evidence that all London boys, or girls either, are not of the Band of Hope. It is a pitiable sight to see boys and girls of sixteen or eighteen reeling along the streets. All honour to the Bishop and his co-workers, who, we trust, will be supported by hosts and hostesses in the remaining holidays. The beverage at all children's entertainments should be non-alcoholic.

VERRUGA PERUANA.

THE Lima medical journals, *La Cronica Médica* and *El Monitor Médico*, are largely occupied with details concerning the fatal case of self-inoculation in a medical student which we mentioned in a recent issue. The disease is known under the names of Verruga Peruana, Verruca Andícola, and Fiebre de la Oroya, and appears to be peculiar to Peru, being "endemic in certain Cis-Andean localities, especially in Huarochirí and Yauyos y Canta, where the ground is from 3000 to 7500 feet above the sea." The disease is febrile, and is characterised by anæmia and by the appearance of red tubercles of variable size on the cutaneous surface of the body. A special bacillus is said to have been discovered by Dr. Isquierdo, Professor of Histology in the Faculty of Medicine of Santiago, Chili. This disease seems to have attracted attention from the earliest times, having been known in the time of the Incas. Augustin Zárate, in his History of Peru (1543), mentions a tract of country which is "very hot and very unhealthy, the inhabitants suffering particularly from very malignant pimples (verrugas) or furuncles with deep roots, more dangerous than small-pox and almost as much so as the carbuncles of plague." It is also mentioned by Dr. Cosme Bueno in his *Descriptiones Geograficas*, and by Tschudi in his work on Peru, 1843. The first scientific description of the disease is due to Dr. Salazar, whose graduation thesis at Lima in 1858 was entitled "Historia de las Verrugas." He considered it to be an endemic disease due to a poisonous virus. A considerable number of cases were observed about the year 1870 in districts where great excavations were being made in laying

Digitized by Google

railway lines, and it is worthy of remark that epidemics of pernicious anæmia also took place in Paris, when the boulevards were being constructed, and in Switzerland, amongst the workmen employed on the St. Gothard tunnel; and that during the excavations for the Panama Canal the workmen have suffered most severely from fatal malaria. In 1875 Dr. Nicanor Pancorvo read a paper before the Lima Academy of Medicine, in which he expressed an opinion that the cause of the disease was to be looked for in emanations of sulphuretted hydrogen from the ground; but his views do not seem to be at all largely accepted by the profession in Peru. The whole subject of the etiology of verruga peruana is, however, now being carefully studied, as it is to be largely discussed in the Peruvian medical societies this year.

SKATING.

IT is never safe in this country to speak of the enjoyment of any sport which depends on the weather in an anticipatory sense. At the moment of writing it seems not unlikely that the lovers of skating may find it possible to indulge their inclination at an early date; but when this sheet is in the hands of our readers, it may, for aught we can tell, be quite warm weather. What we have to say, therefore, is more general than particular, and relates to the exercise rather than to its performance. Beyond question skating is one of the finest of sports, especially for females. It is graceful, healthy, stimulating to the muscles, and it develops in a very high degree the important faculty of balancing the body and preserving perfect control over the whole of the muscular system, while bringing certain muscles into action at will. Moreover, there is this about it which is of especial value: it trains by exercise the power of intentionally inducing and maintaining a continuous contraction of the muscles of the lower extremity. The joints, hip, knee, and ankle are firmly fixed or rather kept steadily under control, while the limbs are so set by their muscular apparatus that they form, as it were, part of the skate that glides over the smooth surface. To skate well and gracefully is a very high accomplishment indeed, and perhaps one of the very best exercises in which young women and girls can engage with a view to healthful development.

POLLUTION OF WATER AND MILK.

LAST Saturday Mr. James Bateman, C.E., read a paper on the Pollution of Rural Water-supplies at the Association of Public Sanitary Inspectors, and pointed out the opportunities for contamination of water by surface drainage from manure heaps, piggeries, and land dressings, and the [illegible] to which persons at a distance were exposed, through [illegible] which received infection from admixture with such [illegible] pail-washing or otherwise. Mr. Bateman was of [illegible] that there should be a determined opposition to [illegible] of milk from any but a farm certified [illegible] sanitary authority as being properly drained and [illegible] pure water-supply, for until this became law [illegible] be periodical outbreaks of disease. He was [illegible] hope for any great sanitary reform just yet, but [illegible] of our food-supply must sooner or later claim [illegible] of Parliament, when doubtless that of the [illegible] would have its share, and this danger be [illegible]. We fully endorse Mr. Bateman's remarks, [illegible] that much good would be done if greater attention [illegible] to the sanitary condition of milk farms. [illegible] of milk infection is still in its infancy, and [illegible] indications that milk consumers are not [illegible] risk of disease if their milk-supply be [illegible] where considerable precautions are [illegible], their condition being satisfactory from what is usually understood as the sanitary point of view. The investigation of all the circumstances which may give rise to milk infection requires prolonged and skilled observation; this is needed in the interest of the milk vendor as well as the milk consumer, and we would gladly see the cordial co-operation of all engaged in the distribution of milk in any step which is taken having for its object the increase of knowledge of the means by which milk contamination may occur. To wait for legislation is, we are afraid, to accept as inevitable for some years to come loss of life and loss of money. Knowledge must precede the passing of Acts of Parliament, and there is no reason why milk vendors should not in their own interest assist materially in its acquisition.

LONGEVITY.

IT has been said, with some degree of reason, that the maximum age attainable by man has risen somewhat during the present century over that recorded in former ages. In judging of such a statement some allowance for error must be made. The exact statistical calculations of our day should not, in fairness, be marshalled against the round numbers of less accurate traditions. The fact remains, nevertheless, that the limit of seventy years is now very frequently passed. Fourscore may even be reached by some without excessive labour and sorrow, and we have among us nonagenarians who carry on with still respectable proficiency the activities of their prime. Such effective longevity is a bright spot in the history of our advancing civilisation. Its comparative frequency, and its association with different physical types, suggest a certain generality in its origin, and encourage the hope that it may be, in some measure at least, dependent on personal conduct. It has been stated that no such condition can influence the length of life after middle-age. After that period inherited vital force is the only potential factor. To some extent this may be granted. If we fix an average of conduct, and suppose that a number of persons conform to it, we should certainly find the purest and most powerful constitutional types outlive the others. For instance, a gouty tendency does not enhance the prospects of old age. A rheumatic one is little better in this respect. The scrofulous are heavily weighted in the race of life by the chances of several infirmities. Nervous persons, again, are wiry, and may live through much trouble in virtue of their elastic tenacity. Then there are nondescript diatheses, which, except in their remote history, present no definite physical bias. Theoretically, these are most likely to furnish, under ordinary usages, the old men of a given time. It will be at once evident, however, that these are general statements, and that an unlikely individual will often exceed his own expectation of life, and by care, or from the suitability of his circumstances, will reach old age. In weighing the value of constitutional tendencies, moreover, another nearly related quality should be considered. This is disposition. The mind of a man must be more or less of the nature of his body, and accordingly we expect to find, and do find, that mental habit reflects in preferences, variations, rate of action, and the like, the type of processes in the lower tissues. So far disposition is merely a part of constitution, and cheerfulness, hope, apathy, or gloom are only expressions of physical change. That all such qualities react upon the body in such a way as to influence its vitality is undoubted. On the other hand, they may certainly be overruled by the action of the will, so as to be no longer mere bodily impulses, but trained servants of a governing intellect. They may thus acquire a compensatory value in correcting faults of constitution, and strengthen in proportion the tenure of life. This brings us to the sphere of intelligent effort. There can be no

Digitized by Google

doubt, in our opinion, that there is much room for exercise of private judgment and energy in seeking the prolongation of one's own life. If there is any known diathetic fault, this implies a law of one's being which will repay in a gain of vitality the man who recognises it and guides himself accordingly. The doctrine of the survival of the fittest does not work itself out by blind chance, or without evident design, even among the lowest forms of life. Much less is it to be believed that man is unable so to adjust his circumstances to his needs as to continue to live after a certain mean period. The weaker will sometimes prove himself the more tenacious of life by observing rational methods of living, of which the more robust is careless. Moderation has probably more to do with success in this respect than anything else. To eat sufficiently, and drink stimulants sparingly, to alternate work with adequate rest, and to meet worries heartily, will afford to everyone the best chance of arriving at a ripe old age.

HYDROPHOBIA.

As time wears on the aspect of M. Pasteur's experiments have a more and more favourable appearance. The number of individuals under his care must now be considerable, but still time is necessary to show how far his treatment has been successful. This must be so from the nature of the case, seeing that so few bitten by rabid dogs ever develop hydrophobia. M. Pasteur meanwhile cannot complain of want of confidence in him, for his doors admit not only large numbers, but also members of the medical profession—assuredly not a slight tribute to his personal renown. The Professor has, it appears, consented to receive a Hungarian doctor as a pupil, to be nominated by the State. With the object of giving facilities for the carrying out in London of M. Buisson's plan of treatment by means of baths, provision has been made for the reception of patients at an establishment in Wilton-place, Belgravia. It seems that a "dread of mad dogs" was highly prevalent in 1765, and the "Annual Register" of that date asserted that the whole nation was "actually groaning under the malignity of its influence." "The people sally from their houses with that circumspection which is prudent in such as expect a mad dog at every turning. The physician publishes his prescription, the beadle prepares his halter, and a few persons of unusual bravery arm themselves with boots and buff gloves in order to face the enemy if he should offer to attack them. In short, the whole people stand bravely upon their defence, and seem by their present spirit to show a resolution of not being tamely bitten by mad dogs any longer."

DR. MEZGER AND THE POPE.

THE announcement that Dr. Mezger of Amsterdam has been summoned to the Vatican to attend the Pope has once more directed attention to a mode of treatment extensively practised on the Continent in many diseases of nervous origin. Massage is of considerable antiquity as a remedial agent, but it was not until the publication of Mezger's classical paper in 1868 that it received what may be called official recognition. The different steps of the procedure have to be carried out in a certain definite order, and no little skill is required for the due performance of the various manipulations. It has no connexion in any way, as is often ignorantly supposed, with rubbing or shampooing, but constitutes in itself a definite mode of treatment. The great danger, in this country at all events, is that it should fall into the hands of unqualified persons. No *masseur* or *masseuse* should under any circumstances be allowed to undertake the treatment, unless under the immediate direction of the patient's medical adviser.

SIR JAMES CRICHTON BROWNE.

THE honour of knighthood is well bestowed in the case of Dr. Crichton Browne. At the comparatively early age of forty-six, with a career in medicine dating from 1861, he has well won his spurs as a scientist, and will wear them not only worthily but with the esteem of his profession. In what we like to call the physiological pathology of cerebral disease and in the applied science of psychological medicine Dr. Crichton Browne has rendered important services to his profession and to the public. Notably did he serve the community last year, when, successfully overcoming the opposition offered to his benevolent enterprise by the officials of the Education Department, he aroused public attention to the fact that, under pretence of educating the brain of the juvenile population, the administrators of an ill-advised code and of a short-sighted system of payment by results were really stunting and crippling the brains of the rising generation, with every reasonable prospect of projecting the baneful influence of their mistaken policy on to the succeeding generation, and perhaps the next. The futile endeavour of Mr. Fitch to counteract the effect of Dr. Crichton Browne's report will be fresh in the recollection of our readers, and they will rejoice that not only was the obstructive effort abortive, but that the truth and energy of Dr. Crichton Browne's enterprise have been acknowledged as they deserved to be. Sir James Crichton Browne has our hearty congratulations, and in the recognition of a well-earned honour the whole profession will join.

ALLEGED ILLEGAL ABORTIONS.

ON December 31st, William Turnbull, surgeon, and Mary Nottage, midwife, were committed to take their trial on the charge of having caused the death of Charlotte Louisa Clifford by procuring abortion. The facts relating to the case, as disclosed at the inquest, have been published in our columns. There have been several remands at the police-court for the attendance of a Mrs. Burton, supposed to have been an important witness, as it was alleged, and indeed admitted, that it was she who introduced the girl Clifford to the male prisoner, for what purpose constitutes one issue the jury at the Central Criminal Court will have to decide. Previously to the hearing at the police-court on Dec. 31st Mrs. Burton died, and an inquest was held by Dr. Thomas, coroner for Central Middlesex. At the latter inquiry it was given in evidence by Mr. Pepper that the death was owing to pyæmia following abortion. The uterus was enlarged in every way, and at the fundus a portion of placenta was found attached. There had been some pelvic cellulitis, resulting in abscess; and the neighbouring lymphatic glands were much enlarged, and one had suppurated. The left knee-joint and both wrists were distended with pus, and the calf of the left leg was in great measure destroyed by suppuration and sloughing. There was no recent peritonitis, but several organised adhesions between the pelvic viscera showed there had been inflammation at a distant date. It will be remembered that whilst Clifford was residing in the house of Mr. Turnbull, where she subsequently died, Mrs. Burton sent a messenger to inquire as to the state of her health. The husband of the deceased woman, Burton, deposed that Dr. Raynor was the usual medical attendant of the family, but that his wife at the commencement of her fatal illness refused to have him called in, but insisted on having Mr. Turnbull. This gentleman continued to visit deceased up to the time of his arrest for having, according to the theory of the prosecution, procured an illegal abortion on Clifford. From that time Dr. Raynor attended Mrs. Burton, whom he found extremely ill with acute inflammation of the joints and an offensive discharge from the vagina. Unfortunately for the interests of justice no depositions were taken from Mrs. Burton, so

Digitized by Google

that her knowledge of the affair must in great measure remain unknown, except so far as it can be gathered from collateral circumstances. She is reported, however, to have admitted that she might have miscarried, and that she "had taken a lot of stuff in rum." The coroner's jury found that Mr. Turnbull was chargeable with having caused the death of Mrs. Burton by procuring abortion, and the magistrate, Mr. De Rutzen, has commited him to take his trial on the charge at the next sessions of the Central Criminal Court, which commence on Monday next.

FIREPROOF DRESSES.

So much attention has been directed to the recent deaths from burning at Stoke, that it may be well if we indicate in general terms the methods by which ball-dresses and other delicate fabrics can be rendered incombustible. There are many chemicals employed for this purpose, the most popular, perhaps, being tungstate of soda. It is comparatively inexpensive, and by the outlay of a couple of shillings the dresses of the whole household may be protected from fire. To three parts of good dry starch add one part of tungstate of soda, and use the starch in the ordinary way. Should the material not require starching, dissolve 1 lb. of tungstate of soda in two gallons of water, well saturate the fabric, and then let it dry. It will not affect in any way even the most delicate colour, and ironing does not interfere with the efficacy of the process. Muslin so treated may be held in the flame of a candle or gas lamp without catching fire, so that, although the part in contact with the flame may be charred or even destroyed, there is no danger of its spreading. In the Exhibition of 1872 Mr. Donald Nicoll exhibited a starch which possessed the property of rendering the finest cambrics and muslins not only uninflammable but almost incombustible. It has always been a matter of surprise to us that some of the makers of washing powders should not have turned their attention to the subject. Ladies should decline to purchase light dress materials which are not shown to be practically fireproof.

In reference to the means to be adopted to lessen the injury likely to be sustained by an individual whose dress unfortunately has become ignited, Mr. John Marshall has contributed to a lay contemporary some judicious hints. As he states, the best course to pursue for a person in such circumstances is to throw himself or herself flat on the floor, so that the flames, which ascend, should not be capable of attacking the head and upper part of the body, where the most serious injuries are usually sustained.

AMMONIA IN ANTHRAX AND CARBUNCLE.

DR. LEONIDAS AVENDANO, in a paper read before the Union Fernandina, a Lima medical society, testified to the great value of ammonia in anthrax and "carbunculous diseases." Indeed, he expressed his opinion that it "is a specific, and that it should be the only drug used." In cases of malignant pustule, he advises that after an incision has been made, some drops of the official solution of ammonia should be introduced into the wound with the hope of destroying the bacilli there and of the ammonia finding its way into the circulation before the bacillus does and thus converting the blood into a fluid in which the parasite cannot multiply. In addition, some ammoniacal salt, such as the acetate, should be given internally, and on the slightest suspicion of general infection resort should at once be had to intravenous injections of ammonia, in doses of ten drops of the official solution diluted with an equal quantity of distilled water. In cases of malignant œdema and carbunculous fever, too, "the microbe should be attacked directly in the blood, ammonia being injected into the circulation." The author detailed several cases in which immediate improvement and ultimate recovery had taken place in patients apparently moribund by the use of repeated ammoniacal intravenous injections. He concluded by claiming for Peruvian medicine the honour of having suggested and proved the value of intravenous medication in no less than four different diseases: Dr. Leno Alarco having first injected chloral in tetanus, and ammonia in septicæmia or purulent infection; Drs. Armando Vélez and F. P. del Barco having employed capsicum injections into the veins of yellow fever patients; and Dr. Néstor Corpancho and himself having originated the treatment above described in carbuncle.

ESCAPE OR RESCUE FROM A BURNING BUILDING.

IT ought to be generally understood that, whether in escaping from a burning building or in endeavouring to rescue a person who has been unable to escape, the aim should be to keep the head as low as possible, by stooping or crawling, as, although smoke is heavy, the purest and most easily respirable air will nearly always be found in the lower stratum of the atmosphere, near the floor or ground. Another point to note is that with the aid of a damp but not wet cloth, such as a blanket held over the head and face, but far enough from it, a considerable atmosphere may be carried around the head sufficient to last for some two or three minutes, if the precaution be taken of breathing as little as possible, and through the nose instead of the mouth, the object being to avoid irritation of the larynx or air-passages, which would produce cough, and by emptying the lungs necessitate deep breathing, with disastrous results. The blanket or cloth, if damped, must not be made sufficiently wet to generate steam, or the heat will have an exaggerated effect, and the length of time during which respiration is possible will be seriously abridged. Great self-possession is the first essential condition of a successful exercise of courage in connexion with fire. Every act must be carefully though quickly thought out, and the peril clearly understood and intelligently faced, or no good service for self or others can be successfully performed.

CHOLERA NOSTRAS AND CHOLERA ASIATICA.

DR. J. SEMMELINK, formerly principal medical officer to the Dutch army in the East, points out, in his recent studies on the history of cholera, what, in his opinion, is the relation of cholera nostras to cholera Asiatica. Certain birds—for example, hens—lay their eggs during a considerable portion of the year without any contact with the male bird; and the eggs, though in all appreciable respects precisely similar to fertile ones, are nevertheless sterile, the difference between the two sorts being altogether hidden from the physiologist. So also, the symptoms of cholera nostras and Asiatic disease, including the rice-water evacuations, collapse, and other typical signs, are such as to prevent even the most experienced physicians from deciding as to the precise nature of certain cases. And yet it is maintained there are between the two diseases essential differences, the vital one being that cholera asiatica is transmissible. Cholera nostras represents, according to Dr. Semmelink, the sterile egg, the fertile egg corresponding to the Asiatic disease. Referring then to Dr. Koch's recent researches, he is inclined to consider that the comma bacillus in the Asiatic disease may constitute the difference between the transmissible and the non-transmissible affections. Dr. Klein's recent researches do not bear out this view in so far as the pathological organism in question is concerned; but it is quite possible that micro-pathology may some day afford the means of distinguishing between cholera asiatica and cholera nostras.

Digitized by Google

There is, however, in many outbreaks, no sharp line between the behaviour of the two diseases in so far as their sporadic or epidemic character is concerned; and it is quite likely that an organism common to the two affections may, under some circumstances of soil, climate, and other surroundings, acquire a power of reproduction and of transmissibility which it would otherwise fail to do, and that the essential difference between the two diseases may be brought about by the influence of these surroundings, rather than by the presence in one of them of a definite organism which is altogether absent in the other.

MOTOR PLATES IN PERIPHERAL PARALYSIS.

THE experimental researches of Gessler on traumatic peripheral neuritis have been made on guinea-pigs and lizards. He has been at pains to determine the modifications that the terminal plates in muscles undergo from the onset of paralysis to the commencement of the cessation of muscular excitability, to the full development of the degeneration, and through the final regeneration. Five or eight days may pass without any signs of degeneration in the terminal plate. Fourteen days after the operation, however, the nuclei of the sarcolemma are seen to be multiplied, and the muscular fibres atrophied; in the muscle plates the nuclei are proliferated, whilst the nervous fibres still preserve their integrity. After twenty-eight days, when the inexcitability has attained its maximum, the muscular fibres are profoundly wasted, the nuclei of the sarcolemma are increased in number as well as the granular nuclei of the terminal plate, whilst the chloride of gold method fails to reveal the presence of any nerve fibres. When eighty days have elapsed the muscle is found to be infiltrated by connective tissue, and the wasting has reached an extreme degree. When it occurs regeneration sets in about the sixtieth day, and the first stage consists in the restoration of the terminal motor plates. All the changes are still slower in the cold-blooded animals. The paper may be consulted in the *Centralblatt für die Med. Wissensch.* 1885, p. 475.

CHRISTMAS IN THE HOSPITALS.

IN most of the metropolitan hospitals the usual Christmas festivities have taken place, and the hearts of the inmates gladdened by suitable presents—to the children toys and fruit, to adults articles of clothing and sums of money. The decorations of the wards in these institutions were in many instanes excellent, and reflect credit on the taste and ingenuity of those who were responsible for them. The world may, as pessimists would have us believe, be growing daily worse, but Christian charity has not been extinguished, as is proved by the efforts made during the past fortnight by the healthy and the wealthy to cheer the lot and brighten the lives of those unfortunate sufferers condemned to spend their Christmas in a hospital.

EYE DISEASES IN WHITE AND COLOURED RACES.

AN interesting paper on the "Comparative Frequency of Eye Diseases in the White and Coloured Races in the United States" appears in a recent number of the *Archives of Ophthalmology*, from the pen of Dr. Burnett, who has paid special attention to the subject. Taking the various diseases from a topographical point of view, he finds in the first instance that the diseases of the conjunctiva occur with about the same frequency in the two races. Scrofulous conjunctivitis, including herpes of the conjunctiva and herpetic ulcers of the sclera and cornea, is most frequent in the coloured races. It is remarkable, however, that trachoma is almost unknown amongst the black race, and is rare even amongst the mulattoes. Dr. Burnett thinks that the trachoma granule or follicle is a deposit of material analogous in character to tubercle, since, like tubercle, in disappearing, the tissue in which it is embedded is destroyed and a cicatrix is the result; and, further, in the circumstance that each fresh attack of trachomatous inflammation is the manifestation of a fresh deposit, and when successive crops of them occur total destruction of the mucous membrane is seen, as may be observed in most old cases of trachoma. In regard to diseases of the cornea, there is in the negro a disproportionately large number of cases of inflammation of all kinds. The proportion of cases of iritis is nearly twice as great in negroes as in white people, though the percentage of syphilitic iritis is about the same. On the whole, Dr. Burnett is of opinion that in cases of operation the prognosis for the negro is as good as for the white man, though the negro is more liable to secondary iritis.

SMOKY CHIMNEYS IN COLD WEATHER.

A SMOKY chimney is an exceedingly great nuisance in a sick room, and even after the well-known method of creating a draught by holding a newspaper against the front of the grate, so as to create an up-draught by preventing a down-draught, has been adopted, the chimney will smoke in cold weather. This is because the upper part of the chimney is cold, and the fire in the grate has not power enough to heat the column of air sufficiently. Good may be done by lighting a fire in some room on a higher floor, the flue of which is in contact with the upper part of the chimney from the sick room; but the best plan probably is to create a blaze—if the chimney has been recently swept, and it is safe to do so—by placing on the top of the fire some sticks and paper, or one of those wheels of fire-wood which are sold prepared with an inflammable material. The purpose is to raise the temperature of the upper part of the chimney as rapidly as possible, and to keep it well heated. It may not appear worth while to make this self-evident suggestion, but as a matter of fact no one can see much of the sick in private houses without being struck with the relative greatness of the discomfort to which they are exposed by failure to adopt what would seem obvious precautions. It is necessary, therefore, to assume that matters so simple as this even are too often forgotten or unknown.

THE OVERHEAD WIRES AGAIN!

The first heavy fall of snow in London this season has already broken down many of the wires that stretch across squares and streets in most localities, and nothing but good luck has prevented the occurrence of fatal accidents. When will London be in the same enviable state as Chicago, with respect to this matter? In the American city, about 3000 miles of electric wires have been put underground, and it is estimated that all the wires in the business portion of the city will be underground by May 1st.

EXPERIMENTAL DENUTRITION.

THE quantity of soluble substances in an organ increases after its removal from the body. According to Quinquaud, these substances are precisely like ordinary waste products of the living organism. The organ is placed under certain conditions of temperature, aeration, and sterilisation; so it is believed that there is no actual decomposition. Hence the name denutrition, which may on Quinquaud's view be regarded as a posthumous descending metabolism or disintegration. By employing the comparative method, observations of the quantity and quality of an aqueous extract obtained from various organs may be made. It was ascertained that the spleen, liver, and lungs were the organs in which disassimilation was most active; it was less marked

Digitized by Google

in voluntary muscles, in the heart and brain, and most feeble in osseous tissue. Carbonic acid, and especially oxygen gases, were found to promote denutrition, whilst hydrogen and nitrogen hindered the changes. Chloroform, ether, and alcohol in feeble doses repressed denutrition, whilst hydrocyanic acid favoured it. Further development of the subject can alone show whether this method of investigation will enable physiologists and therapeutists to penetrate further into the mysteries of nutrition and the mode of action of drugs.

PATHOLOGICAL SOCIETY.

AT the annual meeting for the election of officers for the ensuing year, the scrutineers of the ballot (Dr. F. Willcocks and Mr. D'Arcy Power) declared that the gentlemen nominated by the Council had been duly elected; the list was published in the last issue of THE LANCET. The most noteworthy change is the resignation of Dr. Goodhart and the appointment of Dr. Coupland as hon. secretary. Mr. Butlin, hon. secretary, read the report of the Council, indicating the continued prosperity of the Society, which numbers altogether 682 members. Dr. Charles West proposed, and Dr. Thomas Barlow seconded, the resolution that the report of the Council and the balance sheet of the treasurer be received, adopted, and printed in the Transactions of the Society. Mr. J. W. Hulke, F.R.S., proposed, and Dr. W. B. Hadden seconded, the chief vote of thanks of the meeting in a resolution expressing the feelings of the Society at the able and admirable manner in which Dr. Goodhart, the retiring secretary, had conducted the affairs of the Society during his three years' tenure of office. This vote was carried with cordial demonstration. The vote of thanks to the other retiring officers was moved by Dr. Pye-Smith, and seconded by Mr. Swinford Edwards.

VISITORS TO SMALL-POX HOSPITALS.

IN his last annual report on the Western Hospital belonging to the Metropolitan Asylums Board, Mr. Sweeting refers to a certain number of persons who were admitted into the small-pox wards within thirteen days of having visited the hospital to see patients who were dangerously ill. Such persons, themselves receiving the infection, must necessarily constitute a source of danger to the outside public as soon as they sicken from the disease they have contracted; and Mr. Sweeting suggests that, since nothing short of the compulsory revaccination of all visitors to the small-pox wards will get over the difficulty, submission to that operation should be invariably insisted upon. Visits are already restricted to dangerous cases, and, if revaccination were enforced, a serious risk would be avoided and a substantial benefit would at the same time be conferred upon the visitors. During the year small-pox occurred amongst some convalescents, and Mr. Sweeting, failing other sources of infection, is obliged to suggest as possible that the infection was due to aerial transmission.

THE CASE OF HENRY PATRICK.

WE are glad to observe that the course suggested by our[illegible] in reference to this case has been taken, and that on consideration it has not been deemed decent to hang a [illegible] epileptic. There must always be enough of doubt [illegible] conditions such as these whether the perpetrator of [illegible] criminal in itself ought to be punished as if he were [illegible]; and when the alternative issues are instant [illegible] on the scaffold or deferred death in penal servitude, [illegible] expedient that the convict should have the [illegible] doubt. The case of Henry Patrick is not one [illegible], but servitude under surveillance, and this [illegible] to his fate.

AN OLD ANATOMICAL PREPARATION.

PROFESSOR ROTH of Basle has recently been engaged in investigating the history of a remarkable relic which the University of Basle possesses. It is a skeleton prepared by the founder of anatomy, Andreas Vesalius, and as it bears the date 1543 it may be justly regarded as the oldest anatomical preparation in existence. Professor Roth has published a pamphlet upon the relations of Vesalius with the old Swiss town, from which it appears, contrary to previous ideas, that the great anatomist only once took up his residence in Basle—viz., in 1543, when he came from Padua for the specific purpose of seeing his great work, "De Humani Corporis Fabrica," through the press of Jo. Oporinus, and that during that visit he undertook no official teaching. The dissection of the human body was at that time most reluctantly allowed by the authorities, and it was only occasionally that the body of a criminal was sent to the medical schools, such a concession having previously to 1543 happened only once in Basle—viz., in 1531; and one may imagine the intense longing for such an opportunity on the part of the University students and professors to occur whilst Vesalius was with them. Their desire was gratified. On the 12th of May in that year one Jacob Karrer was beheaded for a murderous assault upon his wife, and the body was handed over to the University, to be dissected by Vesalius. On the afternoon of that day, and for many days afterwards, the great master taught to students and teachers a new anatomy; and when the dissection was completed he prepared the skeleton, and with his wonted generosity presented it to the University—a gift in those days of no trifling value,—where to this day it remains, in the words of the inscription, "Artis et industriæ suæ specimen." As the possessor of the only known relic of the greatest of human anatomists, the University may well be proud of its treasure.

MEDICAL CONTRACT BY TENDER AT THE CAPE.

THE Government of the Cape of Good Hope have set a thoroughly vicious example of how *not* to make medical appointments. Wanting medical men to attend convicts employed in restoring the roadway through Meiring's Poort, in the divisions of Oudtshoorn and Prince Albert, the Commissioners of Crown Lands advertise that they will be prepared to receive tenders. Hitherto such duties have been assigned to duly qualified practitioners at fixed allowances. Now they are to be assigned by tender, as if medical men were ready to compete at a kind of Dutch auction. We hope the Commissioners will consider whether this is the way to get good medical servants, even for convicts.

THE EAST-END TAILORS.

THE special report of our Sanitary Commission on the Polish colony of Jewish tailors in the East-end of London, which we published on May 3rd, 1884, still continues to bear good fruit. Reproduced by the Jewish and the local papers, this report gave rise to a violent paper warfare. Many meetings were also held, and a trade union of working tailoresses was formed under the auspices of the Women's Protective League. Some years previously the men engaged in this branch of tailoring—i.e., the "slop work" done by foreigners in the East-end of London—had also attempted to organise a trade union. Special difficulties, however, stood in the way, and the society never became strong enough to influence the trade. Overwork under the most insanitary conditions has continued to be the rule. The description by Mr. Lakeman, Inspector of Factories, of the poisonous atmosphere in which they work fourteen hours consecutively confirms the complaints made in our report. It is fortunate that many of the details

Digitized by Google

given have found an echo in the press, for the problems involved will not solve themselves. By trade associations, and the exercise of their political influence, the skilled and better educated artisans of England have obtained a reduction of the hours of labour, and sufficient wages to enable them to live in a fairly healthy manner. But these advantages, secured after many years of arduous struggle by the "aristocracy of labour," cannot be acquired by the half-starved exiles from Russia who work with the residuum of the East-end population. In this case the elements of self-regeneration are not strong enough; and therefore outside help, such as that which Mr. Lakeman has attempted to give, is as justifiable as it is necessary.

ROYAL BOTANIC GARDENS, CALCUTTA.

THE annual report of Dr. King, the superintendent of the Royal Botanic Gardens, gives some interesting information regarding the work done during the year 1884-5. There were 12,056 plants received and 23,433 sent out from the garden, and there were 1201 packets of seeds received and 2972 distributed. The subject of the cultivation of fibre-yielding plants received special attention; an attempt to introduce the plantain from which Manilla hemp is derived (*Musa textilis*) proved a failure, the plants being killed by the low temperature of the cold season. The *Sanseviera Zeylanica*, which furnishes an admirable fibre, not difficult of extraction from the plant, has been found to grow well, and a number of plants of it have been distributed during the year. The Japan paper mulberry, the bark of which furnishes one of the best materials for paper, has thriven remarkably well, and Dr. King is in hopes that it may be extensively cultivated on the odd corners of land near the villages. The *bhabur* or *sabai*, to which he directed attention in his report for 1877-8, "has now become a recognised material for paper, and is largely used in local manufacture." A number of green stems of the *rheea* were given to "persons interested in discovering an efficient, cheap method of extracting the fibre." In connexion with the important discovery of the anæsthetic properties of cocaine, the cultivation of the coca plant received much attention, with a view to propagating it for distribution. The condition of the gardens appears to be very satisfactory, and the conservatories are reported to be in as high a state of efficiency as possible.

ARTIFICIAL TEETH.

ANOTHER warning against the practice of not removing artificial teeth at the time of retirement to bed is reported. Miss Turnerelli, sister of a Roman Catholic priest at Sunderland, was found about a week ago struggling and choking in bed. The interior of her throat was horribly lacerated, and three false teeth found embedded in it were with difficulty extracted. The shock proved fatal, and the unfortunate lady succumbed to her injuries. For the sake of cleanliness as well as comfort, and the removal of a grave peril to life, these products of our civilisation should invariably be removed at night-time, and it is to be hoped that other wearers of these appliances will profit by a contemplation of the sad fate that has befallen Miss Turnerelli.

PIGMENTARY HEPATIC CIRRHOSIS IN DIABETES.

HYPERTROPHIC pigmentary cirrhosis has been carefully described by MM. Hanot and Chauffard as occurring in the course of diabetes mellitus. M. Letulle has met with two other cases of the kind, and these are well reported in No. 20 of the *Bullet. et Memo. de la Société Méd. des Hôpitaux*. In the first case, that of a man aged forty-eight, there was melanoderma and contractions of both palmar fasciæ; the autopsy revealed the hypertrophic cirrhosis, and pigmentation of the heart, lungs, and spleen. The second case, also a man, aged sixty-two, had no ascites and no melanoderma, but there was purpura hæmorrhagica. It is curious that in the first case, where there was excessive pigmentation of the hepatic cells, the glycosuria disappeared some weeks before death. Two excellent plates illustrate the morbid conditions in the liver. The author is chiefly concerned with the subject of the origin of the pigment, and believes it to be formed from hæmoglobin.

THE FUTURE OF THE MEDICAL CONGRESS.

WHETHER it be the spirit of the Christmas-time, or the late, but sure, triumph of good feeling over all disintegrating and discordant sentiments, several journals of the States are beginning seriously to discuss the terms of a compromise to obliterate controversy and establish the success of the Congress. The proposal of the *Medical News* is for a union of the present Executive Committee with the original enlarged General Committee, and for this joint body to begin the work of preliminary organisation *de novo*. We adhere to our view that outsiders do best in leaving all healing processes to those on the spot. Domestic differences are best adjusted at home. We abstain, therefore, from expressing any opinion on any particular suggestion. We only say "Blessed are the peacemakers," and repeat the expression of our hope that, for the sake of the profession in the United States and throughout the world, this great cause may be yet crowned with such success as a united profession in the United States cannot fail to ensure.

DETERMINATION OF THE SEX OF THE FŒTUS.

THE possibility of determining, or rather of making a good guess at, the sex of a fœtus before birth has occupied the attention of a good many observers at various times. One of the latest contributions to the elucidation of this question is supplied by a paper by Señor Juan B. Bidart, who examined 100 cases—ninety-nine in the maternity ward of the San Francisco de Borgia Hospital in Santiago, Chili, and one at home—his own wife, in fact. His observations were mainly directed to rapidity of the beats of the fœtal heart at the termination of pregnancy; and the conclusion he arrived at was that when the number of beats is below 135 a minute the child is usually a boy, and when the number is above 145 it is generally a girl. He found that under these circumstances he could diagnose the sex correctly in 92 per cent. of the cases. When, however, the beats were between 135 and 145 it was quite impossible to do more than guess at the sex. Frequent examinations must be made before the rupture of the membranes so as to obviate the chance of mistaking a temporary irregularity for the ordinary rhythm. Of course the auscultation must be made in the intervals between the pains if labour has already commenced.

SURREPTITIOUS PRACTICE.

WE feel that it is our duty to call attention to a pernicious custom becoming daily more prevalent, which if persisted in, must in time materially affect those cordial relations which have hitherto existed between medical men and our large charitable institutions. We refer to the casual and surreptitious private practice frequently carried on by the resident medical staff outside the walls of the hospital. If a surgeon choose to take his house-surgeon or dresser to a private operation to give the anæsthetic or assist him in any way, no objection can be raised; but when a member of the resident staff, contrary to the rules of his office, takes on himself to act the part of a consultant, or, under cover of a friendly interest, give gra-

Digitized by Google

tuitous advice respecting the conduct or progress of a case under the care of another physician or surgeon, we cannot resist the conclusion that a grave error of judgment has been committed. Temptations of this kind are thrown in the way of those holding posts at hospitals, and they are not always easy to resist, especially when a qualification to practise has only recently been obtained; but a little consideration will, we are sure, serve to convince even the most unthinking that any departure from the strict line of rectitude and professional honour cannot but be attended with the gravest consequences.

PORTRAIT OF DR. WILKS.

THE profession will be gratified to know that the portrait of Dr. Wilks, published by Mr. D. H. Menzies, 154, West Regent-street, Glasgow, is a very satisfactory one. The ample dome, the thoughtful expression, and the whitened locks of the great physician and pathologist of Guy's are all well rendered in a picture which presents a skilful and an effective combination of the art of photography and lithography. It is a valuable contribution to medical portraiture.

DISPENSING PRACTITIONERS.

EVERY now and again hard things are said by the lay press, and even by members of our profession, writing "at large," against practitioners who dispense. It should be generally understood that when a qualified medical man dispenses his own prescriptions, it is done not because he likes to do so, but because there is some reason why the course taken appears necessary, or at least expedient. Endeavours to make the public suppose they are not as well served when the practitioner is also the dispenser are unworthy. Everyone who knows anything about the facts must be well aware that this is not true. Meanwhile, we are clearly of opinion that it is better that practitioners should only prescribe, not dispense; and anything like an overture on the part of druggists to render this universally practicable, in towns at least, will, we are assured, be hailed by the profession as a boon. The difficulties of solving problems of possibility are, however, very great, and no hasty measures or sweeping change in this matter will succeed.

RESTORATIVES OR STIMULANTS.

OF late the subject of refreshments for messengers, waiters, and others who are accustomed to serve the public convenience, has received considerable attention. The suggestion that tea, coffee, or cocoa should in such cases take the place of spirituous liquors comes in good time. It has long been a recognised fact that drinks of the former class were much to be preferred to those containing alcohol, in conditions of ordinary health, whether as sustaining strength under fatigue or as opposing the action of cold. The suggestion is therefore worthy of general adoption. The reform which it would introduce into social usage has been found to work well under the most trying conditions of travel and amid the hardships of war, and is at least deserving of a more extended trial at home.

SAFETY ON RAILWAYS.

We are glad to see that the Amalgamated Society of Railway Servants, speaking through its secretary, insists strongly, in the interests of safety, that "overwork on railways is highly dangerous, and ought to be abolished." No wiser words express this opinion too forcibly. It is simply a [illegible] of danger to over-work men upon whose [illegible] and quickness of attention and presence of mind the safety of life and limb depends.

FEMALE LABOUR AT COAL-PITS.

MR. ELLIS LEVER has just published a statement which deals, among other matters, with the condition of women employed in the Lancashire mines. Young girls are included in this class. Their work certainly is not quite so heavy as that of the men, inasmuch as actual tunnelling does not fall to their lot. Short of this they would appear to do anything. They carry, load, bank, and screen the coal, and they dress as men when convenient for working purposes. We have before objected to this misuse of the energies of the female sex. Physically, women are not designed for such occupations. With every allowance made for the possibilities of evolution in a race bred from birth among the pits, it must still be evident that coal-heaving is, at the colliery as well as the depôt, a labour of which only strong men are really capable. To impose it on women is to overstrain them. Socially and morally, it is difficult to see how anything but coarseness of tone and the degradation of domestic life can result from this system. The practice is far from being general in other coal districts, and we sincerely hope that Mr. Lever's disclosures may help to liberate the mining body in Lancashire from their unfortunate pre-eminence in maintaining it hitherto.

THE profession in St. Petersburg has been somewhat excited by some selections which have recently been made to some rather coveted hospital appointments. The question of nationality has been rather unpleasantly obtruded, the "thorough Russians" complaining that they are being elbowed out by Germans, and their opponents retorting that there are many hospital superintendents whose names are German, and who may be of German descent and even speak German at home, but they are all bound to be Russians, and that they certainly have no better chance of appointments than anyone else. Whatever they get is obtained by their own worth and ability.

THE hospital physicians and surgeons of Paris, to the number of 106, have signed a petition addressed to the Minister of the Interior, praying that the *religieuses* in the hospitals to which they are attached may be retained. In the present temper of the French people, it is thought that this petition will not be granted; but in the interests of the sick, who are most closely concerned with the matter, it is to be hoped that it will not be disregarded without careful consideration.

AT the meeting of the Wigan School Board on the 5th inst., a report from the medical officer of health was read on the prevalence of measles in the borough, and the suggestion was made that the usual Christmas holidays should be prolonged. The closure of the public elementary schools has frequently been effectual in checking epidemics of measles, and there is no doubt that the same satisfactory result will in a short time be attained in Wigan.

THE Committee of Management of the Aberdeen Royal Infirmary have at last decided to consult an architect as to the improvement of the present building and the capabilities of the site. It is a pity that this was not done before; still, better late than never. Mr. Saxon Snell has been selected to advise the committee, and will visit Aberdeen for that purpose early next month.

IT is stated that Dr. Herbert Watney, who at the general election unsuccessfully contested Greenwich against Mr. Boord, has been invited to become a candidate in the Liberal interest for the vacant seat for Croydon.

Digitized by Google

THE Paris correspondent of the *Daily News*, in a recent letter to that paper, gives an interesting account of a visit he paid last month to the Hertford Hospital, an institution for the treatment of anyone born wherever the Queen's sovereignty is acknowledged, and maintained, at a yearly cost of between £4000 and £5000, at the sole expense of Sir Richard Wallace.

OWING to the great prevalence of scarlet fever at Leicester, and to the probability that it is mainly propagated by children attending the elementary schools while in an infectious condition, these have, on the suggestion of the sanitary authority, been closed for three weeks, instead of the few days usual at the Christmas holidays.

MR. T. HOYLE, son of the late coroner, has been appointed by the City Council to the coronership of Newcastle-on-Tyne. We are sorry that the Council did not embrace the opportunity of electing a medical man.

ON the 5th inst., the death occurred, at Bath, of Mr. E. C. Holland, L.R.C.P., M.R.C.S. The deceased, who was in his seventy-first year, had for some time suffered from cancer in the neck.

DR. HAGENTORN has resigned the Professorship of Surgery at Kieff.

IT is estimated that there are now in the United States 120,000 practitioners of medicine, including non-graduates.

THE ITALIAN HOME OFFICE ON CHOLERA IN 1884-85.

SIGNOR MORANA, Secretary-General to the Minister of the Interior in Rome, has just issued an elaborate report on the cholera epidemic in Italy during 1884 and 1885. His facts, in the main, are already familiar to our readers; the conclusions he draws from them are interesting, as those of an intelligent and fair-minded official.

In 1884, in compliance with public opinion and the advice of the highest medical authorities in Italy, an attempt was made to bar by force the entrance of cholera through the Alpine passes, and, also by force, to limit its ravages to certain foci of infection. This system of defence was not, according to Signor Morana, without results. It retarded the invasion and it limited its spread; "but in substance it did not attain the end for which it was designed."

In 1885, following the counsels of an international conference attended by the greatest lights in hygiene from every country, and with the experience of the past year as a guide, Italy refrained from the policy of material force; removed the frontier barriers and sanitary cordons, and, while maintaining the usual defensive measures at sea, left the land open, but never lost sight of possible importers of the cholera germ, and even accompanied them with wakeful and suspicious eyes to their very domicile. This precaution, according to Signor Morana, succeeded in detecting the disease as imported by various travellers, and so in isolating and suppressing it. But he confesses it did not attain the supreme end of securing exemption from the epidemics, which, indeed, eluded even the quarantine afloat and effected a landing in Sicily.

"The conclusion," he says, "is inevitable, that the only certain means of successfully resisting the shock of the epidemic is that of facing it boldly and so intercepting it, to which end the primary means are—good personal and local hygiene, isolation and stamping out of the first cases, effective drainage, disinfection, and the wholesale destruction of all articles even suspected of impregnation with the disease, so as to destroy its means of life, of reproduction, and of propagation."

But clear and precise as his conclusions are as to the worthlessness of quarantine by land and sanitary cordons, Signor Morana's Italian critics are loth to part with a means of defence which a section of the population seems to make necessary in Italy. An able writer in the *Nuova Autologia*, just published, says *à propos* of this population: "We admit that such defensive measures are not called for in the case of ordinary travellers or in that of well-to-do families who are fleeing from the epidemic. From Naples, in the first two or three days of September of 1884, the trains kept pouring thousands of fugitives into Rome, without importing a single case of disease into the city. But when we have to deal with the flight and the home-return of masses of operatives, things take quite a different aspect. Here lies the distinction between us and the northern countries. We have, picking up their livelihood abroad, thousands upon thousands of poor compatriots who, on the outbreak of an epidemic, either take to flight or are constrained, even against their will, to return to their native home from want of employment. Among these are mendicants, rag-dealers, itinerant musicians, and vagabonds of every shade. In 1884 there was a stampede to Italy of persons who had been stricken with the cholera at Toulon; some of them had been employed in bringing the victims to the epidemic; others, again, had bought at Toulon and Marseilles articles already used by the dead, or coming from sources more than suspected. To disarm ourselves entirely against an immigration of this kind seems to us a capital error. On the other hand, Austria, Germany, France, Belgium, Holland, and Denmark send few or no such *industrianti* abroad, and therefore have to defend themselves only against ordinary travellers, who, as we have shown, are not dangerous. We ought, therefore, to be very wary in adopting provisions or systems from other states which live under different hygienic conditions." The contention is not without a substratum of truth, and explains the otherwise unaccountable partiality which Italy retains for defensive measures long abandoned elsewhere.

One important point made by Signor Morana is his proof that in the winter of 1884-85 cholera was still in Italy long after municipal bulletins as to its presence had ceased to be issued. On February 15th there was a case at Afragola; on March 3rd another at Crevalcore; on the 7th another at Capannori, and so on through all the successive months till its explosion in Sicily, chiefly at Palermo. Long before it appeared at Marseilles it was numbering victims and giving every evidence of its virulence in the Alta Italia, in Central and Southern Italy, and even in communes and provinces which had remained exempt from it in 1884. But no steps were taken to arrest it in this stage. One of the most valuable conclusions to be drawn from Signor Morana's report is the necessity of stamping out cholera when in a state of hibernation, so to speak; when, as in the past winter, it had been reduced to manageable dimensions and its victims were counted by units. The hygiene, personal and local, the isolation of first cases, the drainage, the disinfection, the destruction of suspected articles—admirable prescriptions in themselves—are apt to be postponed till long after the enemy has effected a foothold, and when all they can do is simply to diminish the mortality. This has been eminently the case in Italy, where, as Signor Morana further points out, there is a strange reluctance, not to say incapacity, to admit that the disease is really Asiatic cholera, even when every symptom betrays its character. For instance, in 1884, at Pancalieri, the malady declared itself on July 20th in two cases, but these were set down as simply cases of "gastric disturbance" until the 27th, by which time twenty-four cases and eight deaths brought the local authorities to their senses. Notably at Spezia and Naples, and in 1885 at Palermo, the malady had for weeks been an unobserved or unacknowledged guest, and was not recognised in its true character till after it had assumed epidemic proportions. With such tardy, imperfect diagnosis, Signor Morana has no difficulty in showing that land quarantine or sanitary cordons, even if efficacious in themselves, have not a chance of proving their efficacy.

DEATH UNDER CHLOROFORM.—Last week we recorded a death from chloroform occurring in Newcastle-on-Tyne. In the same city another has since occurred. The deceased was eleven years old, and the drug was administered for the purpose of facilitating the reduction of a dislocation of the hip. The jury at the inquest returned a verdict of "Death from misadventure," and exonerated the medical attendants from all blame.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6322 births and 4[illegible] deaths were registered during the week ending [illegible]nd, being the fifty-second week of 1885. The [illegible] death-rate in these towns, which had been [illegible]0, and 19·3 per 1000 in the preceding three weeks, [illegible] week to 25·3. This increase was mainly due to [illegible] registration from the previous week, the last two [illegible] which were Christmas Day and Bank Holiday. During [illegible] thirteen weeks of last quarter the death-rate in these [illegible] averaged only 20·0 per 1000, and was 2·6 below the [illegible] rate in the corresponding periods of the nine years [illegible]. The lowest rates in these towns last week were [illegible]all, 17·7 in Brighton, 18·4 in Sheffield, and 19·6 in [illegible]d. The rates in the other towns ranged upwards [illegible] in Preston, 29·5 in Manchester, 31·7 in Halifax, and [illegible]ottingham. The deaths referred to the principal [illegible] diseases in the twenty-eight towns, which had been [illegible]95 in the previous two weeks, further rose last week [illegible]; they included 168 from whooping-cough, 163 from [illegible], 49 from diarrhœa, 41 from diphtheria, 38 from "fever" [illegible]cipally enteric), 34 from scarlet fever, and 4 from [illegible]-pox. No death from any of these zymotic diseases [illegible]ceeded last week either in Norwich, Wolverhampton, [illegible]x; they caused the highest death-rates in Bolton, [illegible], and Nottingham. The greatest mortality from [illegible]-cough occurred in London, Cardiff, and Bolton; [illegible]sles in Bolton, Nottingham, and Plymouth; from [illegible]ver in Leicester and Birkenhead; from "fever" in [illegible]nd Portsmouth. The 41 deaths from diphtheria [illegible]25 in London, 3 in Birmingham, 3 in Salford, 2 in [illegible]m, and 2 in Liverpool. Small-pox caused 6 deaths [illegible]he residents of London and its outer ring, 2 [illegible]ool, and 1 in Bristol. The number of small-pox [illegible] in the metropolitan asylum hospitals situated in [illegible]d London, which had declined in the preceding [illegible]ks from 90 to 48, further fell last week to 41; the [illegible] to these hospitals, which had been 13 and 9 in [illegible]us two weeks, were but 2 last week. The [illegible] Small-pox Hospital contained 7 patients on Satur[illegible]ne case having been admitted during the week. [illegible]s referred to diseases of the respiratory organs in [illegible] which had been 503 and 383 in the preceding two [illegible] rose last week to 610, and exceeded the corrected [illegible] by 94. The causes of 128, or 2·9 per cent., of the [illegible] the twenty-eight towns last week were not certi[illegible]d by a registered medical practitioner or by a coroner. [illegible] causes of death were duly certified in Portsmouth, [illegible], and four other smaller towns. The largest pro[illegible] of uncertified deaths were registered in Hull, [illegible], and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The rate of mortality in the eight Scotch towns, [illegible] been 24·1 and 22·9 per 1000 in the preceding two [illegible]ther declined to 21·6 in the week ending Jan. 2nd, [illegible]·9 below the mean rate during the same week in [illegible]y-eight English towns. The rates in the Scotch [illegible] week ranged from 17·7 in Dundee and 18·4 in [illegible] to 27·3 in Paisley and 29·9 in Perth. The 528 [illegible] eight towns showed a decline of 32 from the [illegible] the previous week, and included 13 which were [illegible] whooping-cough, 8 to "fever" (typhus, enteric, [illegible]·6 to diarrhœa, 3 to scarlet fever, 2 to diph[illegible], not one either to small-pox or measles; [illegible]y 32 deaths resulted from these principal [illegible]eases, against 56, 51, and 43 in the pre[illegible] weeks. These 32 deaths were equal to an [illegible] of 1·3 per 1000, which was 1·6 below [illegible]tes from the same diseases in the twenty-[illegible] towns. The fatal cases of whooping-[illegible] had been 7 and 12 in the preceding two [illegible]s last week, of which 9 occurred in Glasgow, [illegible]burgh, and 2 in Aberdeen. The 8 deaths from [illegible]lso showed an increase upon the numbers in the [illegible]wo weeks, and included 4 in Glasgow, 3 in Edin[illegible]d 1 in Paisley. The 6 deaths attributed to diar[illegible]wed a considerable further decline from recent [illegible] and were 5 below the number in the [illegible] of last year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 178, 175, and 151 in the previous three weeks, further declined last week to 143, and were 31 below the number returned in the corresponding week of last year. The causes of 88, or nearly 17 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 34·4 and 22·8 per 1000 in the preceding two weeks, further rose to 37·1 in the week ending January 2nd. During the thirteen weeks of last quarter the death-rate in the city averaged 27·0 per 1000; the mean rate during the same period did not exceed 19·5 in London and 19·0 in Edinburgh. The 251 deaths in Dublin last week showed an increase of 97 upon the number returned in the previous week, and included 32 which were referred to the principal zymotic diseases, against 23, 28, and 16 in the preceding three weeks; 17 resulted from whooping-cough, 6 from "fever" (typhus, enteric, or simple), 6 from diarrhœa, 1 from measles, 1 from scarlet fever, 1 from diphtheria, and not one from small-pox. These 32 deaths were equal to an annual rate of 4·7 per 1000, the rate from the same diseases last week being 3·6 in London and 1·0 in Edinburgh. The fatal cases of whooping-cough, which had been 8, 15, and 10 in the previous three weeks, rose last week to 17, and exceeded the number in any previous week of the year. The deaths referred to "fever" and to diarrhœa also showed a considerable increase upon the numbers in the previous week. Thirteen inquest cases and 6 deaths from violence were registered; and 79, or nearly a third of the deaths, were recorded in public institutions. The deaths both of infants and of elderly persons showed a marked increase upon the numbers in the previous week. The causes of 37, or nearly 15 per cent., of the deaths registered during the week were not certified.

"HYPOPION" AND "HYPOPYON."

To the Editor of THE LANCET.

SIR,—In the ophthalmological section of your interesting summary of the Annus Medicus for the year 1885 you refer (presumably) to the condition of pus in the anterior chamber of the eye under the term *hypopion* (see THE LANCET, Dec. 26th, 1885, p. 1197.) Though this is a common way of spelling the word, it is, I submit, incorrect, and should be *hypopyon*. So far as the word hypopion is applicable to a pathological condition, it denotes, not a collection of pus, but an extravasation of blood into the lower eyelid—in fact, what is called a "black eye." Both the words "hypopion" and "hypopyon" are to be found in the works of Hippocrates and of Galen, or in the writings ascribed to them, as well as in the writings of many other Greek medical authors; but their meanings are never confounded. "Hypopyon" is derived from *ὑπόπυον*, and primarily signifies a collection of pus anywhere; whereas "hypopion" comes from *ὑπώπιον*, and primarily signifies the part of the face under the eye.

In the seventh book of the *Epidemics*, which has been erroneously ascribed to Hippocrates, mention is made of certain swellings about the knees and feet which resemble purulent infiltrations, *ὥσπερ ὑπόπυα*. Later, however, the term "hypopyon" was applied commonly, if not exclusively, to pus in the anterior chamber or in the cornea. In the treatise *Medendi Methodus* Galen not only definitely states that pus in the eye is called "hypopyon," but gives an interesting account of the practice of a contemporary oculist, named Justus, who cured many hypopya by shaking the patient's head. The word is similarly employed in some of the spurious Galenic writings, and from the time of Galen forwards is not infrequently used by the other Greek medical authors.

The word "hypopion" underwent a characteristic change before it dropped out of ordinary use. Originally it was employed to signify, as already stated, the part of the face under the eye (see Hippocrates, *de Intern. Affect;* Ruffus Ephes., *de Appell. part. corp. hum.*, lib. i., cap. vi.; Oribas, *Medicin Collect. de Ruffi Comment.*, cap. i.; *et al.*) Later,

Digitized by Google

doubtless from the frequency of the lesion, the term came to signify an ecchymosis of the lower lid (see Galen, *de Compos., sec. loc.*, lib. v., cap. i.; Pseudo-Galen, *lib. de Virt. Centur.*, cap. iv.; *lib. de Med. fac. parab. ad Solon*, cap. xii.; Oribas, *Euporist*, lib. iv., cap. l.-li.; *de Virt. Simplic.*, lib. ii.; *de rebus à A incip.*; Aëtius, *Tetrabib.* ii., ser. iv., cap. ii.; Paulus Aegineta, lib. iv., cap. xxx., *et al.*)

In the case of the two words referred to in this note, it will be seen that it is of absolute importance not to confound the letters *i* and *y*. Some degree of care and discrimination is more important now, perhaps, than ever, inasmuch as from ignorance of the significance of the letter *y* as a representative of the Greek *upsilon*, there seems to be a growing tendency to adopt a false representative in the letter *i*. I am, Sir, yours truly,

Harley-street, Jan. 1st, 1886. JOHN TWHEDY.

THE REAL CAUSE OF HOSPITAL DISTRESS, AND THE ONLY MEANS OF CURE.

To the Editor of THE LANCET.

SIR,—I have noticed, more especially this Christmas-tide the numerous and urgent appeals made to the public on behalf of hospitals both in the lay and medical press; in the latter, many of these appeals have in a general way been made the subject of editorial remarks urging their importance. It has often occurred to me, and it has been more especially brought home to me at the present time, when I notice the persistent frequency and increasing urgency of these appeals, that the subject is one very little understood by the general public and very little cared for by the profession, whom it most concerns, and this very much to the detriment of both. To go to the root of the matter at once, it is most apparent to me that the real cause of this great and widespread hospital distress is the still greater and more rampant evil—viz., hospital *abuse*. Hospitals, as they now exist, and as at present managed, by granting aid to all who seek it within (and in many cases without) their walls, without exercising any discrimination as to the real fitness of the individual patient, are not only needlessly and heedlessly squandering the money of the benevolent, but they are at the same time inflicting a real and crying injustice on the large body of general practitioners who may, unfortunately, be obliged to attempt to practise under the shadow of their wings. But in this connexion there is a still greater evil existing, and this is the system that is gradually creeping into many of these institutions—of exacting a fee from all those who seek their aid, arranged on a sliding scale to suit the pocket of each patient. Our profession has never been accused of possessing too great a spirit of unanimity or co-operation; we have, in fact, always been a living contrast to trade-unionism; but for bare-faced robbery of the general practitioner, in order that patients and fees may be provided for the staff of a public institution, commend me to the system which I have now described. Under what plea of justification, I would ask, can any so-called hospital impose fees on patients of an amount equal to in many cases, and falling far short of in the majority of cases, the very moderate fees of the general practitioner? Is the competition fair and honest? Is it not rather carried on and fostered by subterfuge on the part both of the staff and governing body of these institutions? It is my misfortune to live in the immediate neighbourhood of three hospitals: one of these is a large general hospital, where free aid is granted to all applicants without comment or distinction, unless in a gross and very apparent case of what I may call "fraud." If such a case arise, what happens? Why, what I have many times seen is this, that the patient is requested to call the next morning at the physician's or surgeon's private house, and is mulcted in a fee of a reduced character; this may or may not be the proper treatment, according to opinion. I maintain that the proper place for that patient is the surgery of a general practitioner, and he should not be made a source of profit to any member of a consulting staff. And this brings me to another point—viz., Why is this system of total disregard of supervision in the patients fostered, and by whom? I believe, Sir, that it is fostered by the medical staff, and this for the express purpose of enabling them to build up a reputation by its means; for it stands to reason that a better class of hospital patients can have more outside influence than the very poor. That this is no imaginative view I am well assured, for many times have patients of my own, who have been able to afford to pay me bills of pounds, subsequently received free advice at this institution. Then, as to the two other hospitals to which I have referred. In these, payments are exacted from each patient. Some of this money finds its way into the pockets of the staff, and thus, as I have shown, the local medical man is defrauded under the guise of charity. Now, Sir, are hospitals and hospital staffs to be allowed to exist for the purpose of gathering within the walls of the one and the pockets of the other the people who are not poor and the money which should constitute the fees of the general practitioner? And herein lies the remedy: In the large general hospitals eliminate by a careful system of discrimination all but the really necessitous, and enforce in all cases a small charge for medicine (if the patient is a pauper, the parish doctor or workhouse infirmary is the proper place). In all accident cases, when the patients are in a position to pay for attendance they should be obliged to seek private medical aid as soon as their immediate necessities are attended to; and they should not be allowed to continue as out-patients for a long time. Were these suggestions carried out, I believe that the funds of every hospital would be sufficient for its wants; in any case, they would not be misappropriated as at present. With regard to the other class of hospitals of mushroom growth and predatory principles I would, in the first place, remove them from all participation in the Sunday and Saturday Hospital Funds, since they are not *charitable* institutions properly so called; and I would warn the benevolent of their tendencies. In the second place, let the medical men of the neighbourhoods where these exist organise a combined attack, by offering to do all that they do, and not passively to allow as at present their legitimate patients to be swallowed up by spurious and fraudulent eleemosynary institutions. Personally I intend to take this course, and I shall each morning and evening, in an attempt to stem this tide, devote one hour to patients who would otherwise become patrons of these establishments, and my scale of fees will be arranged on the same principles, to suit the pocket of each patient. Thus I shall hope to contribute my iota towards remedying this great evil of hospital abuse, and so alleviate, in some degree, the consequent distress, at the same time practically entering my protest against the wholesale spoliation of general practitioners by their professional brethren under the guise of charity, which here indeed does "cover a multitude of sins."

I am, Sir, yours truly,

Hampstead-road, N.W., Jan. 6th, 1886. JAMES S. M'DONAGH.

THE RELATION OF THE PAROTID TO THE GENERATIVE ORGANS.

To the Editor of THE LANCET.

SIR,—In the last number of the *Medical Times and Gazette* there is an abstract of a paper, read by Dr. Goodell before the American Gynæcological Society, on Inflammation of the Parotid Glands following Operations on the Female Genital Organs. He gives five cases, and ten were added by other members of the Society. Those who are interested in this subject will find in the same journal (vol. ii., 1881, p. 290) an account of five cases of parotitis after ovariotomy, which were published by Professor Möricke. I have a note of a similar case which occurred at St. Bartholomew's Hospital; and Dr. Cribb, of Highbury, allows me to refer to a case where acute parotitis, with a pulse of 120 and a temperature of 104·5°, followed the introduction of a pessary. I have also notes of parotitis after lithotomy and after circumcision. But there are cases where simple parotitis follows pelvic or abdominal injury or disease, without any affection of the generative organs: after gastrostomy (Transactions of the Medical Congress, 1881); after gastrotomy (Transactions of the Pathological Society, 1884); after evacuation of an abscess round the vermiform appendix (Transactions of the Clinical Society, Dec. 1885). And perhaps the parotitis of typhus and typhoid (*Medical Times and Gazette* vol. ii., 1885, p. 839) is of this kind. These cases of parotitis following injury, not of the generative organs, but of the abdominal viscera and peritoneum, may perhaps show that the relation of mumps to orchitis is not due to any connexion between the salivary glands and sexual glands, but to some wider connexion between the glands at the

Digitized by Google

beginning of the alimentary canal and the membrane which is reflected over the rest of it and over the testicles and the female generative organs. This was suggested at the last meeting of the Clinical Society by Dr. Barlow and Mr. Godlee. On the other hand, if the case of parotitis after circumcision, quoted above, was more than a mere coincidence, and if the few published cases of inflammation of the breasts and labia in mumps were more than coincidences, then there may be some special bond between salivary organs and sexual organs. It is said that in camels the salivary glands are enlarged during the breeding season, and Darwin has collected many cases of enlargement of the thyroid and the odoriferous glands in various animals during the same season ("Descent of Man," vol. ii., p. 18). Thus the salivary glands, like these other glands, like the hair on the body, and like the vocal organs, may be related directly to the generative organs. But it would be a good thing if we could get rid of guess-work, and find the connexion, in mumps, not between salivary glands and sexual organs, but between salivary glands and peritoneum.

I am, Sir, yours truly,

Wimpole-street, Jan. 4th, 1886. STEPHEN PAGET.

THE TREATMENT OF PERTUSSIS.

To the Editor of THE LANCET.

SIR,—There seems to be a tendency amongst medical practitioners, even at the present time of rational therapeusia, to consider too much the symptoms of a disease as a basis for their treatment, instead of the *fons et origo mali*. In no complaint have I noticed this so much as in whooping-cough. The medicines for the most part prescribed in this disease have generally an antispasmodic and sedative effect, such drugs as belladonna, bromide of ammonium, and croton chloral hydrate are, as a rule, the favourites. These frequently relieve the spasmodic cough, and, if the patients are cured by their means, it is simply because they are tided over the danger, and the disease is allowed to wear itself out. Now, there is a well-known symptom which is met with in nearly every case of whooping-cough, and that is the occurrence of offensive alvine evacuations; and it was the variation in the character of these, as well as in the number of whoops in certain states of the weather, that led me to make some remarks at one of the conferences held at the International Health Exhibition on July 17th, 1884, in the discussion following Dr. Tripe's paper on "Some Relations of Meteorological Phenomena to Health." If I may be permitted, I will quote from my remarks:[1] "During March and April, 1882, a rather severe epidemic of whooping-cough occurred at Chingford, a small village about ten miles to the north of London. Whilst watching the course of the cases he noticed on several occasions a decided remission in the symptoms, and then at other times a marked aggravation. This induced him to suspect some powerful atmospheric influences at work, and on consulting his charts he found that the increase in the number and violence of the whoops corresponded to an absence or a very low percentage of ozone or other purifiers in the air; whilst, on the other hand, a decrease was accompanied by an extremely deep tinting of the ozone papers. This seemed to suggest a new line of treatment, and forthwith all his little patients suffering from this disease were treated with an antiseptic medicine internally, and the result, he was pleased to say, was very satisfactory; and, moreover, further experience confirmed the plan adopted. He had not yet published in any of the medical journals this new therapeutic of whooping-cough. He would have done it before, but so many specifics had been recommended and found wanting, that he was loth to prematurely risk the possible addition of another to the list of multitudinous drugs of a questionable nature used in this complaint. The present time, however, seemed to be a happy one for making it public. It was just as well to refer to the fact that the [illegible] spectroscope would prove a rough and ready, but reliable, ozonometer to those who did not suffer from colour-blindness, and who possessed the requisite acuteness of vision."

The antiseptic medium referred to above is carbolic acid; [illegible] prescribe with tincture of tolu in as strong a [illegible] is safe to give. Previous to commencing with this mixture, I always order a smart purge of compound jalap powder or compound scammony powder. The result of this treatment I have found to be, almost without exception, highly satisfactory, and in many cases it acts as a very rapid specific. To many readers it may seem almost incredible that this remedy has frequently cured little patients of the kinks and sickness after the administration of from ten to twenty doses of the mixture.

In suggesting the above line of treatment, it is far from my purpose to encourage empiricism, and to advocate these drugs as the only ones that ought to be administered; of course cases are met with where the addition of some other medicine to the above mixture would prove beneficial. I would further add that this remedy, as far as my experience goes, will be found as much a specific for this troublesome complaint as quinine is for intermittent fever.

I am, Sir, yours obediently,

Bournemouth, Dec. 10th, 1885. W. F. CORY.

[1] Clinical Journal of the Royal Meteorological Society, vol. x., p. 284.

SUPRAPUBIC LITHOTOMY.

To the Editor of THE LANCET.

SIR,—From what has lately been very clearly and fully written on the above subject, it would appear to be *the* operation in many cases of vesical calculus. Having performed the operation twice in the last few weeks, I should like to mention what I have not seen suggested, but which very materially simplifies the operation—viz., to introduce a long *well-bent* sound into the bladder, and by depressing the handle to bring the point up close to the pubes; by so doing, the end of the sound is easily felt after the abdominal walls are divided. The opening into the bladder may be made upon the sound, which gives a firm support during the incision. It is not necessary to transfix the bladder with a needle, or bruise it in any way. The sound is retained in the opening until the finger is admitted into the bladder. By this simple procedure it becomes unnecessary to inflate the rectum, with its after-discomfort, or inject the bladder—a proceeding, according to reported cases, not without danger.

I am, Sir, yours &c.,

J. HODGSON WRIGHT,

Dec. 31st, 1885. Senior Surgeon, Halifax Infirmary.

MANCHESTER.

(*From our own Correspondent*)

A NEW PROTECTION SOCIETY.

SOCIETIES for the protection of the interests of the medical profession appear to be on the increase. In addition to those already existing in the metropolis, it was, at the last meeting of the Lancashire and Cheshire branch of the British Medical Association, resolved "That it is desirable that a Medical Defence Society should be formed in connexion with the British Medical Association," and a committee was appointed to inquire into the practicability of the scheme, and to report to the next annual meeting. Amongst the subjects discussed at the same meeting was an interesting one on "Alcoholic Paralysis," by Dr. Dreschfeld, who cited several cases that had come under his notice.

SIR WILLIAM ROBERTS.

The honour of knighthood conferred upon Dr. William Roberts is acknowledged by all to be well deserved by the recipient. Sir Wm. Roberts has done good work in the science of medicine, and has long occupied a leading place in the profession in the north of England. As a compliment to the medical profession generally it is satisfactory, for both law and science, in the persons of Sir Thos. Baker and Sir Henry Roscoe, have had this recognition conferred upon them; but since the death of Sir Jas. Bardsley, now some years ago, no medical man in Manchester has possessed the coveted prefix to his name.

THE NORTHERN COUNTIES HOSPITAL FOR INCURABLES.

At the annual meeting of this institution a letter was read from Mrs. Fraser, enclosing a cheque for £100 in memory of her late husband, the Bishop, and alluding to it as one of his favourite institutions. The number of inmates is at present eighty-four, the limit of accommodation is almost reached, and many applications are constantly received; therefore

Digitized by Google

the committee ask for means to extend the hospital so that 150 patients may be provided for. To do this, £10,000 will be required, and they appeal for this sum to meet a pressing want. The mayor of Manchester presided, and he testified to the economical administration of the institution, stating that for economy and efficiency it came very close to the Eye Hospital, which he had always considered to be in advance of most of our local hospitals in this respect.

INSANITARY CONDITION OF PUBLIC PLACES.

Complaints have of late been frequent and loud as to the deficient hygienic arrangements of two of our much-used public places—viz., the Free Trade Hall and the Coroner's Court. In the former, although a building of large dimensions, the condition of the atmosphere when crowded, as at our large concerts, is often well-nigh unbearable, necessitating the opening of doors, &c., which create draughts so keen that coat-collars are, perforce, turned up for protection. The ventilation is, however, now receiving attention, so that we may hope for better things. It is singular how difficult architects find this (in theory) simple matter of ventilation, especially in our public places of entertainment. The other building referred to is the Coroner's Court, and most medical men in Manchester who have had to attend this dreary place will admit the justice of the complaint that, not only in the ventilation of the court, but in all its surroundings and accommodation, or want of accommodation, it is a disgrace to the municipal authorities of the city.

THE TREATMENT OF INFECTIOUS DISEASES.

That constant source of squabbling between local sanitary authorities and boards of guardians, the responsibility for the cost of maintenance in hospital for patients suffering from infectious disease, has again come up—this time at the Gorton Local Board. This board was startled by the receipt of a bill for £76 from the Royal Infirmary for the use of the Monsall Fever Hospital in August and October only. If the local board had to maintain its own hospital, it would find that this sum would go a very little way towards its expenses. Whether the patients were on the borderland of pauperism or not is rather beside the question, or whether paid for by the guardians or by the sanitary authorities, the money in each case comes from the rates. The important feature is that these should be provided for in some manner that ensures their prompt removal as centres of infection, and at the same time in the most economical manner to the ratepayers. The consideration of this question opens up a much larger one as to the right principle of our present arrangement, and whether a charity supported by voluntary contributions like the Royal Infirmary should expend any of its funds for purposes which it is the duty of the health authorities to provide for.

COMPENSATION TO MEDICAL OFFICERS.

The extension of the city boundaries and the taking in of the Rusholme and Bradford districts has brought up the question of compensating the officials of the local boards of those districts. At the last meeting of the City Council it was proposed to pay an annuity of £24 and £8 respectively to the two medical officers of health of these districts, but there was some opposition to this, and since then one of the city auditors has given formal notice to the corporation that he shall hold its members responsible for any such illegal payments as compensation for loss of office.

The new Eye Hospital is now opened for the reception of out-patients, but the formal ceremony of opening is yet to take place. At present patients are treated at both the old and the new buildings.

Manchester, Jan. 4th.

PARIS.

(From our own Correspondent.)

POST-MORTEM EXAMINATION OF A HYDROPHOBIC PATIENT.

DR. BOCHEFONTAINE has very obligingly furnished me with the following report of the post-mortem examination of the body of the hydrophobic patient referred to in my letter of the 26th ult. The patient who died from rabies in Professor Vulpian's ward at the Hôtel Dieu, on the 11th of December last, was about twenty-seven years of age, and of muscular build. The autopsy was performed on the following day, when the undermentioned characters were noted:—A scar on the left arm about the level of the insertion of the deltoid. Brain: The grey substance of the cerebrum and that of the cerebellum, including the medulla oblongata, were highly congested, and the grey substance of the spinal marrow was also in the same condition. Larynx and trachea: The mucous membrane of these organs presented patches of a dark-red colour. The bronchial tubes, and in fact the whole tissue of the lungs, were of the same hue. An omental hernia was observed on the right side, but without any complication. Nothing particular was noticed in the other organs. The blood was loaded with bacteria. The ventricles of the heart were filled with coagulated blood and with discoloured fibrinous clots.

M. PASTEUR AND INOCULATION FOR RABIES.

The four American boys who, you will have heard, were bitten about three weeks ago at Newark by a dog reputed to be mad were brought to Paris for M. Pasteur's treatment. They were accompanied by a physician, and M. Pasteur inoculated them with the rabic virus on December 21st and subsequent days, the last inoculation having been performed on New Year's Day. They are now on their way to their homes. The youngest of the party, who is only six years old, was accompanied by his mother. I learn that the physician was initiated into the secrets of the preparation of the virus, but he did not take any back with him, as M. Pasteur gave him to understand that the virus would keep but a very few days, and that it would soon lose all its virulent properties at sea. Another American, by the name of Kauffmann, who came over in the *Labrador*, was bitten on Nov. 22nd. He was inoculated by M. Pasteur on Dec. 29th, and, although thirty-eight days had elapsed between the bite and the inoculation, M. Pasteur is hopeful of the successful issue of the operation. Another American, named Sattler, and who is said to be a physician, has also presented himself for inoculation, but M. Pasteur, not finding any scar or mark of a bite, declined to operate upon him. It turns out, however, that it was only a ruse on the part of the American, as he wished to learn the secret of M. Pasteur's mode of operation.

The Minister of Public Instruction of Hungary has written to M. Pasteur, asking him if he would consent to instruct a physician in the steps of his method of inoculation for hydrophobia. The answer being in the affirmative, the Hungarian physician is shortly expected here.

DEATH OF DR. DECHAMBRE.

I regret to have to report the death of Dr. Amédée Dechambre, which took place, from apoplexy, on the 4th inst., in the seventy-fifth year of his age. He was the editor of the *Gazette Hebdomadaire*, and was for many years connected with the Parisian medical press, of which he was the senior member. He was also member of the Academy of Medicine, physician to the Council of State, and officer of the Legion of Honour.

Paris, Jan. 5th.

Obituary.

JAMES MARR SNOW, M.R.C.S., L.S.A.Lond.

THE announcement of Mr. James Marr Snow's death, after a few days' illness, has been received with sincere regret, not only by his professional brethren in Lincoln and its neighbourhood, but also by numerous friends and patients. The deceased gentleman, who had practised in Lincoln for upwards of half a century, was highly esteemed, not only for his professional abilities, but also for his honourable character and kind and courteous demeanour towards all classes.

Mr. Snow was educated at the then United School of Guy's and St. Thomas's, and passed the College of Surgeons and Apothecaries' Hall in 1831. He shortly after commenced practice in Lincoln as partner with the late Mr. Rawlings. For many years he held the appointments of surgeon to the Royal North Lincoln Militia and the Lincoln Blue-coat School, besides having an extensive private practice. Mr. Snow appeared to be in his usual good health when he retired to rest on the night of Tuesday, December 22nd,

Digitized by Google

having been engaged seeing patients until late in the evening. On his servant going to his room on Wednesday morning, she found him partially out of bed. He remarked very quietly that he thought he must have had a shake, as he could not use his left hand, and he also complained of pain in his head. When seen shortly afterwards by some of his medical friends, it was only too evident that effusion had taken place on the brain. The usual symptoms followed, and a calm, painless death took place at 5 minutes past 6 on Monday morning, December 28th. Mr. Snow was buried in the cemetery of St. Mary Magdalene, on Tuesday, December 31st, his funeral being attended by several of his medical brethren and fellow-citizens, who will long bear his memory in affectionate remembrance.

PROFESSOR JOHN C. DRAPER, M.D., LL.D.

BY the death of Dr. J. C. Draper, which occurred on the 20th ult., from pneumonia, after an illness of only four days, New York has lost one of its most popular medical lecturers and authors. Born in Virginia in 1835, Dr. Draper graduated at the University of the city of New York in 1857, having for a year prior to this held the office of house-physician and surgeon of Bellevue Hospital. In 1858 he was appointed analytical chemist in the New York University, a position he retained for thirteen years. In 1860 he assumed the Professorship of Chemistry in the Cooper Institute, but relinquished it in three years; and in 1862 he served as surgeon in the United States Volunteers, and was on General Wood's staff at Harper's Ferry when that place surrendered. Professor Draper was widely and favourably known as an author, several of his works on Chemistry holding an important place amongst text-books. His last work, an advanced text-book on Medical Physics, was published a short time before his death, and such was the absorbing interest this work possessed for its author that the attention he gave it probably hastened his decease.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on Dec. 31st:—

Christopherson, Cecil, Grove House, Blackheath.
Fellowes, William Edmund, Newcastle-on-Tyne.
Lyndon, Arnold, Adelaide-road, S. Hampstead.
Maloney, William Robert Nuttall, Melbourne, Australia.
Young, Charles Wheeler Forrest, The Chase, Clapham-common.

The following passed the examination in the Science and Practice of Medicine, and received certificates to practise:—

Jowers, Reginald Francis, M.R.C.S., Old Steyne, Brighton.
Simcock, George, Mile End, Landport.

THE offertories at York Minster on the 3rd inst. were on behalf of the Royal Medical Benevolent College.

THE death of Joshua B. Lippincott, the well-known Philadelphia publisher and bookseller, is announced.

MEDICAL MAGISTRATE.—Mr. Robert N. Robson, M.R.C.S., L.S.A., has been placed on the Commission of the Peace for the city of Durham.

THE new Russian Society of Children's Doctors has just held its first sitting, Professor Bystroff being chosen president, and Dr. J. J. Radecki vice-president.

THE Glasgow Samaritan Hospital for Women, the first institution of its kind in Scotland, was formally opened on the 4th inst.

FLEET SURGEON SEDGWICK has taken over the duties of Senior Medical Officer of Portsmouth Dockyard, in succession to Mr. O'Malley.

PASTEUR INSTITUTE OF THE CITY OF NEW YORK.—This institution was incorporated on the 2nd inst., its declared objects being the study and treatment of rabies and diseases susceptible of inoculation. The names of the promoters furnish a sufficient guarantee that every effort will be made to attain the results for which the institute has been founded.

THE Austrian Minister of War has ordered compulsory vaccination with calf lymph for the whole of the Austrian Army. The order will be carried out with all expedition.

A DEATH from chloroform has occurred at Tunstall. The anæsthetic had been administered twice to the deceased on previous occasions, and he had come well out of it, but the third time proved fatal.

THE Hospital Sunday Collection in Liverpool will be held on the 10th inst. The amount realised last year was £9216, a sum which, it is to be hoped, will be considerably exceeded on Sunday.

A SENSIBLE RESOLUTION.—At the meeting of the Whitby Board of Guardians on the 2nd inst. several members stated that the amount of stimulants, averaging 9½*d.* per head per annum, used in the workhouse, was, in their opinion, excessive. Common sense, however, at last prevailed, and it was resolved that the matter be left to the discretion of the medical officer.

LONDON HOSPITAL.—On the occasion of the opening for inspection of the new Nursing Home adjoining this hospital, the 150 nurses of that institution determined to signalise the event by presenting their matron, Miss Eva Lückes, with a writing-table. Accordingly, on the 5th inst. they assembled to the number of 140, and the nurse who had been longest on the establishment, in the name of her colleagues, asked Miss Lückes' acceptance of the gift.

PROPOSED PUBLIC PARK FOR WEDNESBURY.—On the 30th ult. a Local Government Board inquiry was held at Wednesbury, touching an application on the part of the local board for sanction to a loan of £5000 for the provision of a public park. The project was opposed by several of the inhabitants on account of the proximity of the proposed site to the cemetery; but since the inhabitants of the town are in the habit of promenading the cemetery itself, this objection can hardly be deemed sufficient ground for the refusal of sanction. The result of the inquiry is not yet known.

OLD MEAT.—On the 5th inst. a butcher was charged before the Brighton magistrates with having on his premises meat unfit for human food. The peculiarity of the case was that there was no specific disease in the meat, nor was it unwholesome through being kept too long, but it was shown that the animal was of great age, and the medical officer of health asserted that the flesh when submitted to him was not fit for food, and that a certain amount of disease was inseparable from old age. The magistrates fined the defendant, who had been twice before them previously, £10 and costs, or a month's hard labour.

HOSPITAL SATURDAY FUND.—The Board of Delegates of this fund met on the 2nd inst., when the Council presented their report for 1885, according to which it appears that £11,192 had been received altogether, and £9500 were awarded to different metropolitan hospitals, dispensaries, and convalescent institutions, being £500 more than in 1884. It is to be regretted that the percentage of expenditure for the year had not been reduced, but this was explained by the fact that there had been a sudden demand upon the funds for a largely increased number of boxes, and the expenditure attending the change of date in the collection.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the annual meeting of this Association, recently held at York, a very satisfactory report by the committee was read and adopted; after which Mr. North, who has been re-elected President, delivered an address, in which he pointed out the advantages of organisation, and recapitulated the various sanitary improvements effected in York during the past year. Papers on Enteric Fever were afterwards read, and an animated discussion followed.—The following is a list of the officers and committee elected unanimously to serve during the ensuing twelve months:—President: Mr. S. W. North (York). Vice-Presidents: Mr. T. W. Hine, M.B. (Bradford), Dr. W. K. Giddings (Calverley), and Dr. Britton (Halifax). Committee: Dr. H. W. Arbuckle (Thorne), Mr. G. Goldie (Leeds), Dr. J. Hardwicke (Rotherham), Mr. A. Roberts (Keighley), Dr. J. W. Mason (Hull), and Mr. W. Burman (Wath). Secretary: Dr. J. Mitchell Wilson (Doncaster). Treasurer: Dr. R. Bruce Low (Helmsley).

THE LATE MR. EBDEN.—In Haughley, Suffolk, some patients and friends have raised a memorial to the late Mr. W. Ebden, who died in 1884, by recasting the tenor bell of the church at an expense of about £30.

DR. PARSONS, one of the medical officers of the Local Government Board, has, we understand, paid a visit to Kidderminster in consequence of statements regarding the water-supply of the town. Mr. Arnold Taylor, one of the engineers to the Local Government Board, will assist Dr. Parsons in his inquiries.

ILLEGAL TITLES. — At Westminster, Mr. Wm. Yelverton Davonport, of Vincent-square, Westminster, appeared to a summons before Mr. D'Eyncourt, to show cause why a distress warrant, to satisfy a fine of £10 and five guineas costs, should not issue and be levied on his effects. Mr. Pridham, solicitor to the Medical Defence Association, appeared to support the summons; and Mr. E. D. Rymer represented the defendant. In May, 1884, Mr. Davonport, who styled himself a surgeon on his cards and doorplate, and practised as a doctor in the Vauxhall Bridge-road, was mulcted in the sum of £15 5s., fine and costs, for representing and describing himself as a qualified surgeon without possessing the necessary diploma. Mr. Davonport then contended that having passed the surgical part of the College examination, he might call himself surgeon. Notice of appeal was given, but never prosecuted; but this of course was not allowed. Since then he has passed the medical part, but not the midwifery. Mr. Davonport's solicitor begged for an adjournment that counsel might be heard for Mr. Davonport. But the Judge ruled that there had been the fullest opportunity for appeal, and that distress must issue.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—A meeting of this Society was held at 11, Cavendish-street, on Tuesday last, the president, Dr. Norman Kerr, in the chair. The Chevalier de Proskow-Marstorff of Vienna, president of the Austrian Society for the Study and Cure of Inebriety, read a paper on Inebriety in Austria. In Moravia there was one public-house for every 222 inhabitants, and it was sought to reduce this to one for every 500. In Vienna, 6555 drunkards had been arrested in 1884, of whom 5771 were males and 784 females. The taxes on liquors were only one twenty-second of those in Britain. The Austrian Parliament had recently passed a law to check inebriety. Dr. A. Peddie, of Edinburgh, read an elaborate paper on the Habitual Drunkards Act, pointing out its inefficiency and inadequacy to accomplish the objects aimed at. Dr. Peddie insisted on the recognition of inebriety as a disease, and strongly supported the discontinuance of the necessity of habitual drunkards having to sign a declaration before two magistrates prior to being admitted into a retreat. He proposed a simple contract between the applicant and the licensee of the retreat. He was in favour of Government inspection of all patients in houses, and of compulsory committal in certain cases. A discussion followed.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BLUNT, Mr. T. P., has been appointed Analyst for the County of Hereford.

CHILDE, LETTERSTEDT FREDERICK, M.B.Lond., M.R.C.S., has been appointed House-Surgeon to Guy's Hospital.

DINGLEY, B. A., M.D.Lond., M.R.C.S., has been appointed Medical Officer for the Second District of the West Bromwich Union.

EASBY, W., M.D., has been appointed Surgeon to the Great Northern Railway Company for Peterborough and District, vice J. Hair, M.D., resigned.

FARRER, GEORGE A., M.R.C.S., of Brighouse, Yorks, has been appointed Certifying Surgeon under the Factory and Workshop Act, vice Robert Farrer, M.R.C.P., M.R.C.S., resigned.

FENTON, J. S., M.B., B.Ch.Dub., has been appointed Medical Officer for the Second District of the Brackley Union.

FLOYER, WILLIAM WADHAM, M.B.Lond., M.R.C.S., has been appointed House-Physician to Guy's Hospital.

HARRIS, S. C., L.F.P.S.Glas., L.S.A.Lond., has been appointed Medical Officer for the Ely Trinity District of the Ely Union.

HEWITT, FREDERIC W., B.A., M.B.Cantab., Anæsthetist to Charing-cross Hospital, has been appointed Assistant Anæsthetist to the Dental Hospital of London.

JACOB, E. L., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer to the Chertsey Rural Sanitary Authority.

KELLY, P. A., L.R.C.S.I., L.R.C.P.Ed. (of Aliwal North, Cape Colony), has been appointed by the Cape Government to attend the employés on the Local Terminal Section of the Railway as far as Molteno.

MOORE, H. G. H., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the East District of the Bingham Union.

MONTGOMERY, R. J., A.B., M.B., M.Ch. T.C.D., has been appointed Resident Clinical Clerk in the Rotundo Hospital, Dublin.

NORTON, R. R., L.R.C.P., M.R.C.S., has been appointed Medical Officer to the Tottenham and Edmonton Dispensary, vice J. Bunting, M.R.C.S., L.S.A.Lond., resigned.

OWEN, ARTHUR DEAKER, M.R.C.S., L.S.A.Lond., has been appointed House-Surgeon to the Teignmouth Infirmary.

SALTER, JOHN R., M.B.Lond., M.R.C.S., has been appointed Medical Officer for the Third District of the Tonbridge Union, vice Gargory, whose appointment has expired.

SPONG, CHARLES STUART, M.R.C.S., has been appointed House-Surgeon to Guy's Hospital.

SUTTON, ALFRED MARTIN, M.B.Lond., M.R.C.S., has been appointed House-Physician to Guy's Hospital.

SWETE, E. H. W., M.D.St. And., M.R.C.S., L.S.A.Lond., has been appointed Analyst for the County of Hereford.

SYKES, E. J., M.D., C.M.Edin., has been appointed Medical Officer to the Tottenham and Edmonton Dispensary, vice J. Bunting, M.R.C.S., L.S.A.Lond., resigned.

TAYLOR, ALFRED ERNEST, M.R.C.S., has been appointed House-Surgeon to Guy's Hospital.

WALTERS, F. RUFENACHT, M.D. & B.S.Lond., F.R.C.S.Eng., has been appointed an Honorary Surgeon to the Westminster General Dispensary, vice Dr. J. H. Waters, resigned.

Births, Marriages, and Deaths.

BIRTHS.

BALLANCE.—On the 31st ult., at Harley-street, Cavendish-square, W., the wife of Charles A. Ballance, M.S., F.R.C.S., of a daughter.

BARNES.—On the 8th ult., at Umballa, the wife of Surgeon Raylar Barnes, A.M.S., of a son.

EAST.—On the 1st inst., at Clifton-gardens, W., the wife of Edward East, Surgeon, of a son.

PRATT.—On the 29th ult., at Camden House, Blechingley, Surrey, the wife of Alfred Pratt, M.D., of a daughter.

MARRIAGES.

BATTYE—FISHER.—On the 29th ult., at St. Michael's Parish Church, John Howard Battye, M.D., of Denbigh-street, S.W., younger surviving son of the late R. Fawcett Battye, M.R.C.P., to Jemima, third daughter of John Fisher, Esq., of St. Michael's-on-Wyre, Lancashire.

CROSSFIELD—GREENFIELD.—On the 31st ult., at Broadwater Church, Worthing, Sussex, Arthur Kyffin Crossfield, L.R.C.P., of Dartmouth, eldest son of Robert Crossfield, Esq., of Oak-hill, Isle of Man, to Emma, eldest daughter of Walter Greenfield, Esq., of Holmesdale, Worthing.

PESKETT—PESKETT.—On the 29th ult., at St. Mary's Church, Leyton, Essex, by the Rev. Alfred Peskett, M.A., assisted by the Rev. Charles Edmunds, Vicar Designate of All Saints', Arthur William Chalmers Peskett, M.A., M.B.Cantab., son of the late William Peskett, M.D., Surgeon-Major Indian Army, to Edith Jane, younger daughter of Alfred Peskett, M.D., of Leyton, Essex.

TREND—STEVENS.—On the 5th inst., at Christ Church, Lancaster-gate, Theophilus William Trend, M.D., of Southampton, youngest surviving son of the late Rev. Henry Trend, LL.D., Curate of Wembdon, Bridgewater, to Frances Jane Elizabeth, younger daughter of the late R. G. Stevens, Esq., of Rockstone-place, Southampton.

DEATHS.

CROFT.—On the 1st inst., suddenly, at Abbey-road, N.W., John McGrigor A. T. Croft, M.D., F.R.C.P., F.R.C.S., late of the Ceylon Rifles, aged 65.

DAVIS.—On the 19th ult., at Coquimbo, Chili, suddenly, of heart disease, John William Davis, M.D., L.R.C.S.Ed., Staff-Surgeon R.N., H.M.S. *Heroine*, fourth son of Dr. James Davis, of Ranelagh, co. Dublin, and late of Newport, co. Mayo, aged 37.

DOWNES.—On the 31st ult., at Milford Lodge, Craven Arms, Salop, Thomas Richard Collins Downes, M.R.C.S., L.S.A.Lond., aged 68.

HAZEL.—On the 3rd inst., at Oakley-square, N.W., George Hazel, M.R.C.S., aged 64.

JULIUS.—On the 4th inst., at Portland-terrace, Richmond, Surrey, Frederic Gilder Julius, M.D., in his 75th year.

KING.—On the 2nd inst., suddenly, at 6, Albion-street, Hull, Kelburne King, M.D., F.R.C.S., Surgeon to the Hull Royal Infirmary.

LILLEY.—On the last day of the old year, at his residence, 12, Strathblaine-road, St. John's-hill, New Wandsworth, S.W., Dr. Frederick John Lilley (formerly of 242, South Lambeth-road), eldest son of the late Mr. John Lilley, Surgeon, of Wisbech, Cambs., aged 63.

MICKLEY.—On his passage to Sydney, Arthur George Mickley, M.B.Lond.

PAGE.—On the 5th inst., at St. Ann's, Carlisle, William Bousfield Page, F.R.C.S., J.P. Cumberland, in his 69th year.

SCOFIELD.—On the 2nd inst., suddenly, at Grosvenor, Bath, W. J. J. Scofield, M.R.C.S., F.L.S., formerly of Birmingham, and Hampstead, London, aged 56.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, January 11.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M. Also on Thursdays at 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
MEDICAL SOCIETY OF LONDON.—Clinical Evening. Living Specimens at 8 P.M. Mr. A. Boyce Barrow: Cases of Varicocele treated by Excision.—Dr. Isambard Owen: Case of Recovery from Albuminoid Disease.—Dr. C. E. Beevor: Cases of Athetosis.—Mr. Walter Pye: Case of Diffuse Lipoma.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Messrs. Field, Hutchinson, A. S. Underwood, and D. Hepburn. President's Valedictory Address.

Tuesday, January 12.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. Bryce Wright: Exhibition of a Bronze Sword, found by the late Capt. Sir William Peel, R.N., at Sandy, Bedfordshire.—Mr. G. F. Lawrence: Exhibition of Flint Instruments from the junction of the Thames and Wandle.—Dr. R. Munro: Ancient British Lake Dwellings and their Relation to Analogous remains in Europe.—Mr. A. L. Lewis: On Stone Circles in Cumberland.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Gostling: On the Increase in Number of White Corpuscles in the Blood in Inflammation, especially in those cases accompanied by Suppuration.—Dr. Mitchell Bruce and Mr. Bellamy: On a case of Removal of a Tumour from the Roots of the Last Cervical and First Dorsal Nerves.

Wednesday, January 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—7.30 P.M. Council Meeting. 8 P.M. Discussion on Dr. Edwardes' paper on the Report of the German Vaccination Commission.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. G. F. Dowdeswell: On the Microbe of Chicken Cholera.—Mr. A. W. Burnett: Fresh-water Algæ of the Lake District.—Mr. J. W. Stephenson: On Central and Oblique Light in Resolution.
HUNTERIAN SOCIETY.—8 P.M. Dr. Stephen Mackenzie: On Tetany.—Dr. Carrington: Cases illustrating the Treatment of some of the Complications of Acute Rheumatism.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. John Phillips and others.—Dr. Herman: On the Production of the Shape of the Oblique Pelvis of Naegelé.—Dr. Braithwaite: A case of Extra-uterine Gestation treated by Laparotomy in which the Placenta never came away.—Mr. Knowsley Thornton: A case of Removal of both Ovaries during Pregnancy.—Dr. Lewers: A case of Circumscribed Sarcoma of Uterus and Vagina.

Thursday, January 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, January 15.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Dr. Swete: The Suction of Sewer Gas into the Water-supply a Fertile Cause of Enteric Fever.

Saturday, January 16.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
MIDDLESEX HOSPITAL.—Operations 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

BOOKS BOUND IN HUMAN SKIN.

FOLLOWING the example of Mr. Joseph Zachnsdorf, who lately bound two Elzevir editions in human skin, another London binder has recently executed an order to encase a copy of Holbein's "Dance of Death" in the same material—assuredly a most appropriate covering for this work. These are the most recent instances of the use of human skin for such a purpose; but they are far from unique, several criminals in olden days having been, after execution, despoiled of their integument in order that the bookshelves of some *connoisseur* of bindings might be enriched by the ghastly relic.

Mr. W. A. Benshaw.—Our correspondent had better apply to the registrar of the University.

WINTER COMFORTS FOR MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—Mr. Pridgin Teale, in THE LANCET of last week, gave some valuable hints concerning clothing. I would wish to supplement them by the recommendation of a "cardinal" waistcoat—i.e., a knitted one with long sleeves—for very cold weather. The wearing of one, I find renders a heavy top-coat superfluous. On entering a house I unfasten mine, and it slips back out of sight, leaving the ordinary waistcoat visible; the difference in weight and gain of warmth are most desirable. For ordinary winter weather a flannel lining stitched into the back of a summer waistcoat makes it comfortably warm. Considering how little, comparatively, the spinal cord is protected from external variations of temperature by ordinary clothing, I deem this extra warmth important, and have benefited several bronchitic, asthmatic, and other patients by inducing them to have the backs of their waistcoats as warm as or warmer than the fronts. Some correspondence about this appeared in the *Standard* last year. For women also it is desirable to protect the spinal cord from extreme cold.—I am, Sir, yours faithfully,

Malvern, Jan. 6th, 1886. STANLEY HAYNES, M.D.

Mr. F. D. Lys.—Instruction is given at several of the lying-in hospitals—e.g., Queen Charlotte's—or the Maternity Charity, Finsbury-square.

SEPARATE EXAMINATION IN MECHANICS.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me when a student, who has passed one of the preliminary examinations supposed to be recognised by the General Medical Council, but which does not include mechanics as one of its subjects, can obtain a separate examination in mechanics likely to be recognised by the Council as a compliance with their new demands? At present it seems that the new regulations simply disfranchise a large number of the preliminary examinations, including both the Cambridge Previous and the Oxford Mods.

I may say that I have applied at the offices of the General Medical Council, but could obtain neither attention nor courtesy, much less information. I am, Sir, yours truly,

Jan. 5th, 1886. AN ANXIOUS PARENT AND A F.R.C.S.

"A SANE LUNATIC."

THE *Globe* complains that difficulty sometimes arises in placing known lunatics in asylums. It will always be thus, so long as the present clumsy system of certifying is maintained. The filling up of the forms required by law is a task of great perplexity in many of the very cases in which it is urgently necessary to place a person of unsound mind in confinement or under control; whereas in cases of doubtful insanity or mere eccentricity there is not, as a rule, any great trouble in getting certificates duly signed. This is not as it should be.

Mr. R. Stevens.—Jervis on the Office and Duties of Coroners, fourth edition, by Melsheimer; published by Messrs. Stevens and Sons, Chancery-lane.

An Old Subscriber.—We have no knowledge of the system.

MIND AND MATTER.

To the Editor of THE LANCET.

SIR,—With reference to the moot questions of ecstasy, miracles, mothers' marks, stigmata, *et hoc genus omne*, that have been recently discussed or alluded to in your pages, there is a passage in Holcroft's Memoirs, vol. ii., p. 197, which calls, in connexion with wounds &c., for reproduction, if it does not compel adverse criticism or comment. It runs to the effect that Carlisle—the late (as I take it) Sir Anthony Carlisle,—who is described by our author as "an acute and thinking mind," thought that the mind ought not to endeavour to regulate disease, its influence being great, but, as he affirmed, prejudicial. He (Carlisle) "instanced that people having wounds, by a close attention to their feelings in the affected part, increased its sensibility to a noxious degree, and that the bones, which, he said (I think erroneously), have themselves no feeling, had, by the attention of patients fixed upon them when diseased, become entirely sensitive. He spoke of these as facts within his own knowledge." "From my own experience," adds Holcroft, "I believe them to be true, and think with him that the attention so fixed upon parts diseased may be prejudicial; but from experiments made upon myself, if the attention be fixed with a tranquil, pacifying, and cheerful temper of mind, I am persuaded they highly benefit the sufferer. This I urged; but his opinion seemed fixed." It is not easy to see how it can come to pass that the attention of sufferers to their feelings in the affected part may aggravate the sensibility of that part in the one instance without producing a correspondingly beneficial effect, under very similar, and without more favourable, conditions in the other. Yet this is what Carlisle affirms or implies; and I ask your readers how far, if at all, their experience accords with his?

This paragraph suggests three agencies or influences, to the consideration of which I bespeak the attention of such of your readers as can speak about them "as facts within their own knowledge":—1. Can the mind regulate (formed) disease in anywise, and, if so, how far or how much? 2. Can people having wounds increase their sensibility one way or the other—i.e., taking the temperature as the analogue of this so-called sensibility? Can the former be either increased or diminished—no matter how much or how little—by any amount of attention or indifference on the part of the patient? 3. Are the bones (as such) devoid of feeling, and, if so, can they be rendered, by such mental effort or fixation as is here contemplated, on the part of their owner, "entirely sensitive"?

Books, "by the score or more," have been written on these points; but they have been written by sciolists or theorists who had some hobby to ride or some theory to uphold, and facts are what we want in the case. To elicit these in an authentic setting, or from those—and those only—who can speak of them as having come within the sphere of their own knowledge, is the object of this brief note, and the inherent interest of the subject will be my excuse for calling your and their attention to he matter in this place. I am, Sir, your obedient servant,

Auriol-road, W., Nov. 22nd, 1885. WM. CURRAN.

SUBSCRIPTIONS TO CHARITIES.

To the Editor of THE LANCET.

SIR,—I was gratified to read your opposing criticism of the (under present circumstances) absurd proposal of "A Middlesex J.P."—viz., that subscribers to charities should insist that 75 per cent. of their subscriptions should be funded, and only 25 per cent. be used for current expenses. As my letter on behalf of the hospitals, which appeared in *The Times*, brought forth this remarkable suggestion, I trust that you will permit me to say that, although I did not for one moment anticipate that it would be acted upon, yet I replied to "A Middlesex J.P." to the effect of your leader, and also of Mr. Burdett's and Mr. Carr-Gomm's letters—viz., that if the benevolent supporters of charities insisted upon the absurd condition that 25 per cent. only of their subscriptions should be used for present purposes, then by far the greater proportion of the absolutely necessary work of relieving the sick poor in their sufferings from disease and accident would be stopped. Hospital beds would have to be vacated, wards closed, and medical relief suspended to an extent probably little dreamt of in "A Middlesex J.P.'s" philosophy. Not only would there be this immediate sad result, but the carrying out of his suggestion, instead of enabling, as he seems to think, the future work of the medical charities to be extended and more efficiently carried on, would, I believe, cause the subscriptions to fall off, and thus the future, as well as the immediate, operations of the hospitals would have to be greatly curtailed, to the irreparable injury of those for whose benefit they were established.—I am, Sir, yours truly,

Jan. 5th, 1886. THE EDITOR, "CHARITY RECORD."

FEES FOR VISITING A "RETIRED PUBLICAN."

THE Woolwich County Court judge, Judge Powell, seems to have but a poor appreciation of the value of medical services. In a case tried before him last week a medical man sought to recover £3 from a "retired publican" for attendance, which was charged at the rate of 3*s.* 6*d.* a visit. The defendant, who had left the neighbourhood and had been very troublesome to trace, complained—for the first time, though he had had the account in 1882—that 3*s.* 6*d.* was excessive, adding the bit of vulgar abuse that "he had had more skilled doctors for 2*s.* 6*d.*" His Honour "thought the charge rather high"! He, however, gave judgment for the amount claimed. If Judge Powell will ask his own doctor, or look at any of the published tariffs of medical fees—such, for instance, as those in the Appendix to Whittaker's Almanack for last year (they are omitted in this year's issue)—he will see that when people live in houses above the value of £25, it is usual to charge them 3*s.* 6*d.* at the very least.

Dr. Lavers.—The report gives no intimation as to the nature of the supposed remedy.

POISONOUS SNAKES IN NAMAQUALAND.

To the Editor of THE LANCET.

SIR,—Two years' sojourn in a land in which excessively poisonous snakes abound has caused me to direct some little attention to the various remedies which have been suggested to save life when fellow-beings are bitten by snakes of a known poisonous nature. The most deadly snakes here are the puff-adders, the yellow cobra capellas, the horn snakes, and the night adders. Whilst frequently hearing of horses and cattle rapidly succumbing to the bites of these snakes, it appeared strange that the natives themselves, who mostly ramble about the Veldt almost naked, seldom or never appeared to suffer any further inconvenience from the bites of poisonous snakes than would be usual from any accident which would cause a little local inflammation; and, on close inquiry, I found that the natives in Bushmanland, Namaqualand, Damaraland, and the Kalakari are in the habit of extracting the poison-gland from the snake immediately it is killed, squeezing it into their mouths and drinking the secretion, and that they thereby appear to acquire absolute immunity from the effects of snake-bites. The natives, moreover, keep by them some poison-glands which they have allowed to dry in the sun; and they also carry about with them the dried body of a poisonous lizard, known amongst the Hottentots as the "t' nobo." When a native or any traveller who has lived long here is bitten in the Veldt by a poisonous snake, it is customary (whether he be a snake-poison drinker or not) to tie a ligature, if practicable, above the bite, then to suck the wound or cause it to be sucked; make a few incisions close to where the poisonous fangs entered, and insert pieces about the size of a pin's head of the "t' nobo," or, failing the "t' nobo," of the congealed contents of a dried poison-sac. For a long time I hesitated to place much reliance on these methods; but having a month ago seen a native named Snellsteve, who is a snake-poison drinker and a snake collector, put his hand into a box containing two yellow cobras, and several horn and night adders, in doing which he was severely bitten, and has never since suffered anything more than a little pain, such as might be caused by any trivial mishap, I feel I can no longer refuse to believe in the efficacy of the snake virus itself as a remedy against snake poison.

I could quote the testimony of Captain Hills, and Messrs. Ridgell, Fisher, and Kays, who, from five to thirty years spent in the above-mentioned districts, have had undoubted opportunities of observing the action of the remedies; and the result of their observation has been that they now firmly believe in the methods I have mentioned, and never travel without the dried sacs and the "t' nobo."

I am, Sir, yours faithfully,

ALFRED BOLTON, L.R.C.P. Lond.

Port Nolloth, Namaqualand, Dec. 7th, 1885.

Mr. Prowse (Clifton).—We regret we have been unable to find room for the communication.

Mr. A. Allen.—We cannot exchange.

PRURITUS AND COFFEE-DRINKING.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 2nd (page 34) you note the opinion of Brown-Séquard that certain cases of pruritus vulvæ and pruritus ani are associated causally with the use of coffee. The idea struck me as not only a singular one, but as one which in my own experience receives confirmation on the *post hoc* principle at least. For months past I have suffered from pruritus ani, which yielded to no treatment whatever. No constitutional malady was, or is, present; the renal and nervous systems were normal, and digestion good. I was, however, in the habit of taking a large cup of strong coffee after dinner, and relinquished the habit only on account of certain symptoms pointing to interference with gastric digestion. Since giving up my post-prandial coffee I have not had a return of the intolerable itching. Perhaps it may be held that in reality the coffee caused digestive disturbance, and that this latter primarily caused the pruritus. The coffee in such a case would only be the remote, and certainly indirect, cause of my ailment. Be that as it may, the pruritus has vanished with the coffee-drinking. I think of giving the latter a trial again, and of watching the result.

I am, Sir, yours truly,

Jan. 2nd, 1886. A. W.

HYDROPHOBIA: OLD PRESCRIPTIONS.

To the Editor of THE LANCET.

SIR,—At a time when hydrophobia is being so prominently brought before us, and when one of the most eminent of continental scientists is so patiently and laboriously working to try and effect its cure, it may not, perhaps, be amiss to glance back and see how the old physicians treated this and allied dreadful diseases.

Alphonse Karr, one of the most charming of simple philosophers, tells us that "physicians, for a long time, applied the roots of fennel pounded with honey to the bites of mad dogs. At the end of three or four hundred years, it was discovered that this had never cured anybody." For the older doctors, attributing virtues to plants based upon analogy, concluded that fennel must be an antidote to the bite of snakes, because, as Pliny says, snakes are exceedingly fond of it. The Romans drank the seeds in wine as a cure for scorpions' and snakes' stings. And, still reasoning from analogy, I suppose, the French physicians thought that as it was a "sovereign remedy" in these two cases, it must therefore be a potent cure for the bite of mad dogs, and so used it for three or four hundred years. Similarly, Pliny tells us that ancient physicians, observing that snakes used the juice of this plant as a kind of eye salve to clear their sight, immediately applied it to their suffering brethren for a similar purpose. Whence arose the following elegant dog Latin lines, which I feel sure must have been oft-repeated by the "Savantissimi doctores" and "Medicinæ professores" of Molière?

Fœniculum, roses, verbena, chelidonium, ruta.
Ex his fit aqua quæ lumina reddit acuta.

Gerarde, our first great English herbalist, also gives very many quaint instances of similar uses. Thus, in speaking of certain flies which "feed" upon the napellus, he says, "Yet of them there is confected an antidot or most available medicine against the deadly bite of the spider called Tarantala, or any other venemous beast whatsoever; yea an excellent remedy not only against the aconites, but all other poisons whatsoever." But honest Gerarde did not believe in everything which was transmitted to him from his ancestors. For, summing up the virtues of larkspur, he says, "That it is set downe, that the seeds drunken are good against the stingings of Scorpions; whose virtues are so forceable that the herbe throwne before the Scorpion or any other venemous beast, causeth them to be without force or any strength to hurt, insomuch that they cannot move or stirre untill the herbe be taken away; with many other such trifling toyes not worth the reading."

I remain, Sir, yours truly,

University College, London, January 4th, 1886. R. W. BOYCE.

A REQUEST TO CANADIAN PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—I am engaged in correspondence in the local papers with the anti-vaccinationists, and, of course, my chief opponent is at Leicester; but Banbury stands only second to that town as a centre of the movement against vaccination. Your valuable remarks will, I doubt not, have been taken as a cue, and I trust that medical men in every county town will avail themselves of the local press to refute the fallacies that at present are being spread broadcast throughout the country by emissaries from Leicester. My adversary states in the *Banbury Guardian* of last week, that "Dr. A. M. Ross of Montreal, writing on Nov. 12th, 1885, quotes from the Health Office Reports. In August the demand for increased vaccination began, and as vaccination increased from 100 to 200 per week in August to from 1000 to 1500 per week in October, so has the small-pox death-rate increased from 50 to 60 per week in August to 300 and 350 per week in October; thus showing that vaccination kindles small-pox." May I appeal to my brother practitioners in Canada, through the medium of your valuable journal, for statistics, in order that I may let the neighbourhood know the truth. I feel that you will see the importance of my request, and agree with me that it is not well to treat the movement with silent contempt, which would be construed by the public to mean inability to refute the arguments of the anti-vaccinationists.

Can you kindly give any statistics to refute the statements I have given? Can you also tell me any facts with regard to the North American Indians, who were being decimated by small-pox before they accepted vaccination? I am, Sir, yours obediently,

G. COCKBURN SMITH, M.D.

Middleton Cheney, Banbury, Dec. 26th, 1885.

*** We would recommend our correspondent to read the last issued report of the Medical Officer of the Local Government Board, where he will find a large number of facts of the kind he evidently requires.—ED. L.

"SYPHILIS IN CAPE COLONY."

To the Editor of THE LANCET.

SIR,—I have just read in your issue of Oct. 17th an annotation headed as above, in which, quoting from the *Friend of the Free States*, you assert that syphilis is especially rife in Basutoland. I have held the appointment of medical officer to the Basutoland Government since Oct. 1st, 1884, and during that period have only had one case of syphilis under my notice. Framboesia (yaws) is pretty prevalent, and this is mistaken by the public for syphilis. That the disease exists largely in the Cape Colony is, I believe, true; but, on the contrary, I believe Basutoland to be practically free from it.—Yours faithfully,

W. J. V. ROWE,
Medical Officer to the Basutoland Government.

Maseeve, Basutoland, Dec. 4th, 1885.

STATISTICS OF INSANITY: RECOVERIES.

DR. PLINY EARLE, writing in the *American Journal of Insanity*, observes that so far as the statistics presented are an indication, the recoveries in British asylums, both in recent cases and of all patients admitted, exceed the recoveries in American institutions by between 8 and 9 per cent. The most important general conclusions to be derived from the statistics included in this paper are: first, that the old allegation of curability in a very large majority of recent cases is not sustained, and that a failure to sustain it is more apparent and more striking than at any antecedent time; secondly, that the percentage of reported recoveries of all cases received at the hospitals still continues to diminish. He thinks the diminution is perhaps in part attributable to the admission of a larger proportion of chronic cases and of cases of greater degeneracy from their origin, in part to a more stringent interpretation of the word "recovery," and to greater conscientiousness in the compilation of statistics.

Mr. Simeon Snell's paper will appear in an early number.

ACUTE GLOSSITIS: ABSCESS.

To the Editor of THE LANCET.

SIR,—The following case may prove of interest to some of your readers on account of its not being very common:—

On Oct. 14th, 1885, I was called to see a case of swollen tongue. The subject was a little girl, aged eight, pale and sickly-looking, the daughter of a miner; she had always enjoyed fair health up to this time. The family history was good. I found, on examination, the tongue half an inch thicker than natural, and covered with a white fur; it was not painful to the touch; deglutition was difficult and caused some pain; the pulse was 160; the temperature being 103·1°. There was some soreness complained of on pressing over the region of the right tonsil. The tonsil was not enlarged; saliva dribbled copiously from the mouth, the floor of which was quite natural. There was no swelling of glands in the neck, and no apparent cause of the enlargement of the tongue. Inquiry was made as regards the patient ever having taken mercury, &c., but with negative results. She stated that she had eaten a quantity of cheap coloured sweets the day before, and had afterwards vomited. I ordered the usual remedies for glossitis and ice to suck. I saw her again the next day, Oct. 15th. The swelling of the tongue had increased quite half an inch more; the patient could not close the mouth on account of the great swelling and protrusion of the tongue; she had taken no food during the day; she could not swallow even a little beef-tea; the dyspnœa was urgent; she was in an extremely weak condition, the constitutional disturbance being great. The voice was quite abolished, so I resolved at once to deeply scarify the anterior surface of the tongue. I wrapped a tonsil bistoury with lint to within half an inch of the end, and made two incisions, longitudinally, each side of the raphe of the tongue; the mouth immediately filled with curdy pus and venous blood. I may say there was no sense of fluctuation to be felt before the operation. I ordered an enema of beef-tea, brandy, and egg, and a gargle of tannic acid and glycerine, to be painted over the tongue and the back of the throat, with a mixture of bark and chlorate of potash internally. I saw her the next day (Oct. 16th). The swelling had decreased half an inch; she could take beef-tea and milk through a feeder; she slept well; the tongue was quite normal, and the incisions healed; the bowels acted four days after the operation. The patient appeared quite well, but weak. Ordered cod-liver oil. She has remained weak ever since.—I am, Sir, yours truly,

Lower Gornal Surgery, Jan. 4th, 1886. WM. ED. NEWEY.

"AUSTRALIAN MEDICAL APPOINTMENTS."

To the Editor of THE LANCET.

SIR,—In answer to your correspondent "Old Subscriber," who wrote under the above heading in your issue of Sept. 26th, 1885, I beg to say that the medical appointments in these colonies are chiefly club and country hospital appointments. The clubs pay £1 per member per annum, for which sum the practitioner has to attend the member, his wife, and family, and (as a rule) find medicine; midwifery extra (two or three guineas), and mileage at the rate of five shillings a mile if the residence is more than three miles, the first three miles being free. There was a hospital house-surgeoncy vacancy in Tasmania a few weeks ago, salary £350 and a house, for which there were eighteen candidates, the successful one being a London M.B. A man over forty would have to stand his chance; but so far as this colony is concerned, he had much better stay at home. There are about 250 medical men practising in Sydney alone, and fees are little, if any, higher than in England, while house rent and expenses are about double. The hospital appointments range from about £40 to £400 a year. The great want here is not more medical men, but a proper Medical Act. At present any man can style himself "Doctor," and anyone can give a death certificate. We have in Sydney a Chinaman assuming the title of "Doctor," and having a large practice, who was cook at a hotel in the gold-fields; another man, who practises as a follower of Hahnemann, was formerly a groom; while a third advertises himself as curing the poor on certain days, his qualification being the fact that he is a seventh son! We have a new House of Assembly now, and it is possible they may find time to pass a Medical Act.

Now to another matter. A patient of mine, aged eight, swallowed a halfpenny. It passed per rectum in exactly three weeks, and bore no marks of its somewhat lengthy sojourn. Yours faithfully,

Sydney, N.S.W., Nov. 18th, 1885. NOSTALGIA.

Digitized by Google

Mr. Frederic Irving de Lisle.—The situation is a difficult one, especially when the two persons concerned are of the same rank in the profession. B should decline to attend, alleging as a reason the entire concurrence of himself and A. But we are not prepared to say that under all circumstances this extreme position should be maintained; something is due to the feelings of the patients or friends. Of course, we assume absolute honour and high conduct on the part of the preferred practitioner.

PARALYSIS AGITANS.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers could throw out suggestions for the treatment of the following case of what seems to be paralysis agitans. The patient is a woman aged fifty-two years, the mother of four children. She has always been of a nervous temperament, and for many years has had great pecuniary troubles and anxieties. About three years ago she first noticed the tremors, which were then slight and limited to the lower extremities. Now they are almost general (except in the face), preventing sleep, and rendering life wretched. The movements are partially mere tremors; but sudden jerkings are also experienced, which the patient vainly tries to check by holding down one limb with another, or otherwise fixing it. There are also considerable flushings of the face, and noises in the head of the most heterogeneous character. She has tried change of scene, and has used at various times phosphorus, arsenic, strychnine, bromide of potassium, and occasional night draughts of chloral combined with bromide; but nothing seems to procure relief. Can any of your readers suggest anything further? I am, Sir, yours truly,

Jan. 4th, 1886. INQUIRER.

Doubtful.—Our correspondent's view is ingenious; but we should not advise him to take the case into a court of law, where, according to all *past* decisions, he has no *locus standi* as a surgeon.

Dr. A. Wilson (Leytonstone).—Yes, as opportunity offers.

CEPHALALGIA WITH CATALEPTIC SYMPTOMS.

To the Editor of THE LANCET.

SIR,—Can any of your readers give any suggestions as to treatment in the following case?

Miss G——, aged seventeen years, is now suffering from most acute pain in her head, which begins as soon as she awakes in the morning, and comes and goes at short intervals throughout the entire day till bedtime, when she goes into a quiet sleep and so remains till the following morning. She has also occasionally some fits of a cataleptiform description, which last about seven or ten minutes, and when she wakes she screams out and coughs violently for about three minutes, and then relapses into the cataleptic state. She also complains of pains in the chest. She appears unable even to stand alone, and has to be carried from her bed to her chair at the fireplace. The breathing is very short when she is awake, but normal during sleep. The fits are getting each day more frequent, and all the symptoms defy every form of treatment that has been tried during the past five months, and much anxiety is felt by the patient's friends.—I am, Sir, yours faithfully,

Everton, Jan. 5th, 1886. ROBERT B. HUNT, L.R.C.S.E., &c.

Dr. Tindal Robertson.—It would scarcely be fair to other institutions of a like kind to insert the letter of our correspondent.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Lectures
ON THE
SURGICAL TREATMENT OF EMPYEMA.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.

By RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

(*Concluded from page 54.*)

BEFORE discussing the methods of active surgical treatment one word must be said on the advisability of leaving some cases alone altogether. Nature, as has been hinted, probably effects a cure sometimes in children, when, either from the absence of medical advice or a faulty diagnosis, the presence of pus is never made out; but there are also other conditions in which it is at least doubtful whether surgical interference is of any use, and indeed if it be not actually hurtful. In chronic phthisis an empyema may be present and apparently do no harm for a considerable period, but its evacuation may be followed, apparently as a result, by increased destructive changes in the lung; it may certainly, if the greatest care be not taken, be followed by increased constitutional disturbance from inflammation of the pleural surfaces. These cases should then, I think, be left alone as long as the presence of the fluid is not a source of inconvenience to the patient. There is yet another class of tubercular cases where the empyema is in direct communication with a bronchus. Here, again, the advisability of operating depends upon the amount of inconvenience suffered by the patient, and this depends upon the amount of pus which the patient expectorates. It is well known that, if even a small amount of pus be coughed up from a cavity, it may produce much irritation to the bronchial tubes, and the secretion from them, added to that coming from the cavity, may then reach an enormous amount in the course of the day. I have seen a case of a pulmonary cavity not holding more than an ounce which caused more than a pint of expectoration daily; and another of probably the same nature in which the pus, which was offensive though small in quantity, caused the most intense discomfort and copious expectoration, both of which distressing symptoms were relieved by making the patient lie upon her face, the cavity which had been incised being at the anterior part of the lung. Another consideration is that the pus from the empyema may find its way into the bronchi of the opposite side, or into the comparatively healthy bronchi of the same side, and set up destructive changes there. The deduction, then, seems to be that in cases of this kind we may safely let matters alone if the expectoration be slight and the constitutional disturbance and local inconvenience inconsiderable, but not otherwise; though both surgeon and patient must honestly face the fact that a permanent closure of the opening is not to be expected, and thus, though an annoyance and source of danger may be done away with, the not inconsiderable discomfort of a permanently discharging fistula in the side is substituted for it; for these are not cases in which one would feel justified in attempting the operation for removing the rigid elements of the chest walls, or in which, if they were attempted, any permanent good from them could be anticipated. Let anyone who is doubtful on this head consult Estlander's paper in the *Revue Mensuelle de Médecine et de Chirurgie* (1879, pp. 157 and 885). Another class of cases that should undoubtedly be left alone for a time is that in which the empyema is being expectorated, but in which there is no tubercular disease. I say for a time, because there is no doubt that a certain number of them recover spontaneously, and the same observation applies to those in which the pus has found its way into some other cavity, such as the stomach or bowel; but in all of them it is not wise to wait very long, unless the disease is obviously continually advancing towards a cure. Those that open externally very seldom recover without some form of operative interference.

Having decided that something must be done for a recent empyema, the first question that arises is with regard to aspiration. Is it or is it not to be recommended as a rational means of cure? and if so, in what sort of cases? In the first place, it is an undoubted fact that a certain number of cases recover completely after one aspiration, and a still larger number after the process has been repeated a few times. Amongst our own cases there are, as I have said, two in whom aspiration pretty frequently repeated was followed by a cure, and amongst the children there are no fewer than four out of the thirty cases in whom such a result was obtained. F. P., aged three years and four months (Table I., Case 12), was aspirated once three weeks after the onset of the disease; J. D., aged three years (Table I., Case 10), once nine weeks after; H. B., aged four years (Table I., Case 14), four weeks, and M. C., aged six years (Table I., Case 25), four months after the commencement of the illness; and in all the symptoms disappeared without further interference. And these, I feel sure, are not the only cases of the kind which have been met with at the North-Eastern Hospital in the course of the last few years. Still, it must be owned that in the greater number the reaccumulation has been rapid, and there has seemed to be no tendency towards a cure. The experience, therefore, seems to be much the same as that which follows the use of this method in the treatment of ordinary abscesses. Our own cases were both young men, aged respectively seventeen and twenty-one; both, however, were large effusions, and both were right-sided. G. D. was aspirated three times, fifty-two, twenty-six, and nine ounces being drawn off, with a month's interval between; while W. J. S. was only aspirated once, at which time eighty-nine ounces of thin pus were drawn off; and both appear to have made complete recoveries. It seems, I think, clear that aspiration is most likely to be successful in young patients, who are, it must be remembered, much the most favourable for the free incision; in fact, I think, from studying the statistics one may say that those who were thus cured would have recovered quite as rapidly, if not more rapidly, had they been subjected to this operation. They, of course, escape the inconvenience of an open wound, and the more or less prolonged application of dressings; but they run the risk of having left a mass of cheesy inspissated pus, which may possibly be the cause of future mischief. As, however, this risk is rather hypothetical, and as the aspirator is almost as convenient an instrument as any other for making the usual exploratory puncture, I would always use it in the first place in a young subject, and if the fluid were slow in reaccumulating, and then of a more serous character, and less in amount than before, I should evacuate it again after a short interval. It seems only reasonable not to let the cavity become again fully distended, as this distension must not only have the effect of compressing the lung again, and rendering its chance of expansion smaller; but also of irritating the pleural surface, and so making it less prone to absorb the contents. If, after the first aspiration, the accumulation is rapid, or if the pus is as thick as ever, it is best to proceed to the free incision at once; and in any case it is probably wiser not to repeat the process more than two or three times. Aspiration, of course, tends to expand the lung, but it must not be forgotten that if the free incision has at last to be resorted to, the longer the illness has lasted the smaller is the chance of perfect expansion, not only because the tissue of the organ itself becomes more diseased, but also because it becomes coated with a thicker and thicker layer of pleura.

If the free incision be chosen, we have to decide upon the best place to make the opening. There are two important points to be considered: first, to secure efficient drainage; and, secondly, if possible and compatible with the first, to open a part of the chest near that which is likely to close the last. What this part is it is very difficult to decide; certainly not the lower part of the chest, for this usually closes first, the diaphragm being soon drawn out into contact with the chest walls. The lowest part of the chest is therefore to be avoided, because the drainage-tube must on this account be long to begin with, and as the case progresses will almost certainly act with less and less efficiency, and be introduced with greater and greater difficulty. Sometimes it is found in cases that are not doing well (F. G., Table II., Case 13, for instance) that the lower part does

Digitized by Google

not close, and an accumulation constantly occurs there. Under such circumstances it is necessary to make an incision behind in the tenth space, or even the eleventh; it is then occasionally followed by the best results, but this is no argument in favour of selecting this spot in the first instance. One might naturally suppose, as our consulting surgeon, Mr. Marshall, has pointed out, that the neighbourhood of the fifth interspace, near the junction of the ribs and cartilages, would be the last region for adhesion to take place between the lung and the chest wall, but it may be doubted if we have evidence enough to show that this is actually what does occur; while we shall see that, in old empyemata, it is the apex itself that offers the greatest difficulties. I believe, then, that any spot about half way between the upper and lower parts of the chest will be found satisfactory so far as the object under discussion is concerned, and, in my experience, that which affords the most satisfactory drainage, both when the body is recumbent and erect, is a little outside and below the angle of the scapula, about opposite the eighth or ninth rib. I do not wish to deny that cases do extremely well if the opening is made further forwards; and if a spontaneous rupture has already occurred in the axilla, or even more anteriorly, I do not hesitate to utilise this opening in the first instance. The spot mentioned is not inconveniently near the angle of the scapula, so that the tube is not interfered with by the movements of the arm, and the wound in this situation is not found to be a source of annoyance to the patient (as has been urged in objection to it by some) when he is lying in bed. The thickness of the tissues which must be traversed in order to reach the chest wall in this situation adds no material difficulty to the operation, even in people of considerable muscular development.

Having fixed upon the spot, we must next consider the method of making the incision. More often than not I am in the habit of excising a portion of a rib, because I find that in most cases this offers the best, if not the only, chance of satisfactorily investigating the cavity with the finger and of securing thoroughly efficient drainage; and while all are agreed that the latter is of the utmost importance, I believe that the former is scarcely less so. Often large masses of curdy material are met with, which are easily detected and extracted by the finger; and sometimes the finger will, by breaking down adhesions, open up loculated cavities which might otherwise have remained unopened, at all events for a time. Nevertheless, I am not so wedded to this procedure as to advocate it in all cases, and if the ribs are sufficiently wide apart—as, for example, in front, in a fairly well-formed chest—I am content with simply incising an intercostal space. It seems wiser also to avoid doing it, if possible, when the pus is fetid, on the theory that absorption of putrid material is more likely to take place when the bone is cut across; but even this objection is, perhaps, more theoretical than real, for in such cases, after a day or two, we almost always find that the bone is bare where the drainage-tube has been in contact with it. I have never seen any evil consequences from the removal of a piece of rib, and I am confident that great advantage is often gained from it, while it is certain that the bone is in a short time reproduced, so that the rib is as strong as before. In the case of J. E., aged one year (Table I., Case 1), who died eleven weeks after the operation, the rib was quite firm; and the same result has been found in other cases where a second operation has been necessary. Here is the rib of F. S., aged twenty-three (Table II., Case 12), removed, if the expression be allowable, five months after it was first excised. You will see that it is completely consolidated, except for the aperture through which the sinus passed, though the thickness of the rib is not much greater than normal. It has been objected that an inconvenient amount of callus is thrown out after this procedure; but I think the specimen now exhibited will convince you that it is scarcely more than occurs when no bone has been removed at all. If no bone be removed, and the case becomes chronic, it almost invariably happens that two spurs of bone are formed on each side of the sinus uniting the rib above with that below; if a piece has been removed, the rib becomes united both with that above and that below. In the latter case, these three ribs are in close contact; in the former, the two ribs are separated by a distance depending on the size of the drainage-tube which has been employed.

I need say nothing about the simple incision of an intercostal space, but will describe a little in detail what seems the simplest way of removal of a piece of rib. In all cases of operations upon the chest, but especially if one side be much disabled, and still more so if there be much expectoration—as, for example, where one is dealing with an empyema which communicates with a bronchus, or with a case of bronchiectasis,—it is important not to turn the patient more than is necessary on to the sound side. For, in the first place, there may arise risks from the anæsthetic, the increased impairment of the respiratory functions adding the toxic effects of carbonic acid to those of chloroform or ether, and so constituting a real danger to the patient; and, in the second place, such a position increases the probability of the expectorated matter finding its way into the bronchi of the sound lung, and so producing alarming symptoms or actual asphyxia. A case in point, which also illustrates the reason why chloroform is better than ether for such operations, was that of a girl who had one lung much damaged by an empyema which she was expectorating. Ether was administered, and the combination of the "ether bronchitis" with the entrance of pus into the bronchi of the sound lung, added to the already impaired action of the latter, brought her into such a serious state that we were obliged to draw blood from the arm and resort to other active measures in order to keep her alive. We are having made here a high table with flaps on each side to draw aside in the position which will be occupied by the side of the chest, by the employment of which we shall be enabled, whilst sitting down and operating from below, to explore or open an intercostal space far back without turning the patient over at all, and thus avoid the dangers to which I have referred. Of course such a table cannot be always at hand; but if it be not, the same result may be obtained almost as well by bringing the patient to the very edge of the table or couch, and even allowing him to project a little beyond it. Mr. R. W. Parker has employed cocaine with excellent results, and the suggestion seems a most valuable one. The use of a general anæsthetic may be avoided by freezing the part; but it is doubtful if these methods will answer for anything more severe than the simple incision of an intercostal space.

It is also advisable not to raise the arm more than to a right angle with the body; or at least, if this be done, to note the extent to which the skin is drawn up by doing so, and then to pull it down before making the incision through the soft parts. If this precaution be not taken the opening will be found to be valvular, and much inconvenience may arise at a later date in the introduction of the drainage-tube. Should this difficulty, however, arise, it may be obviated by making a second incision upwards at right angles to the first. Such an incision gives more room, and it is not a bad plan to adopt it to start with, especially if the patient be very fat or muscular, rounding off the corners of the small flaps afterwards. The skin being then steadied by the finger and thumb pressed upon the rib, the first incision is carried down to the bone for a distance of two or three inches. After any superficial vessels are secured, the periosteum is divided and raised from the bone, as may most conveniently be done by means of an elevator with a cross handle (an instrument introduced from Germany). The periosteum on the deep surface of the rib may readily be separated by a blunt and slightly curved elevator, which is then thrust beneath the rib to raise it beyond the level of those above and below it. This allows room for the introduction of the blade of a pair of ordinary string-cutting pliers, or that of a pair of forceps which I have had made, one blade of which is blunt and the other sharp, both being slightly curved. The cutting pliers will divide most ribs, but occasionally it is more convenient or even necessary to use a small saw. The rib is divided in front of and behind the elevator, and from an inch and a half to two inches are removed, leaving the periosteum and pleura uninjured and exposed. The knife is then carried through these structures, and, the parts being clearly seen, there is no difficulty in avoiding the intercostal artery, but should this be cut it is now quite easy to secure it and to apply a ligature at once. The opening in the pleura may be made quite small if desired, and increased by introducing the finger or a pair of closed dressing forceps, the blades of which are subsequently expanded. The finger is then introduced into the cavity and a thorough exploration made, and the pus, if aseptic, is allowed to escape under cover of a piece of rag soaked in carbolic lotion, which is placed over the wound. If it be desired to prevent the entrance of air into the chest, a tube with a thin

Digitized by Google

caoutchouc valve, such as that I now show, may be employed; or a still simpler method (of which I have no experience) may be employed—viz., the tying over the end of the tube a sort of petticoat arrangement of linen. The valved tube will work even though the opening be of some size; but for the petticoated tube to be efficient it is necessary that the opening should be only just large enough to fit it accurately. Neither arrangement will, it need not be said, answer well in cases where there are thick flakes mixed with the pus, but when such do not exist the valved tube answers admirably. This was shown in W. B. (Table II., Case 5), where the pus at the first opening was remarkably thick. On the third day, on making the patient expire forcibly, a drop or two of perfectly clear serum alone escaped—a beautiful illustration of the fact that the so-called "pyogenic membrane," if subjected to no irritation either from tension or putrefaction or any other cause, ceases at once to form pus, but secretes only serum.

I feel convinced that the introduction of the antiseptic principle into surgery, coupled with the freedom of drainage which we now always secure, has done much to render the treatment of empyema less formidable than it used formerly to be. I would strongly advocate the employment of the antiseptic treatment, even to its most minute details, for such cases; though freely acknowledging that some putrid cases do quite as well as those in which the pus is sweet. It is a matter of common experience that the opening of an empyema which has not previously putrefied without antiseptic precautions often leads to very serious symptoms, in the same way as severe septic poisoning follows incision of a psoas abscess under similar circumstances, because a large surface and a surface favourable for absorption becomes bathed with a highly putrid material. In the case of an already putrid empyema, nothing but good can come from allowing the septic material a free exit; while in the case of a sweet one tension is certainly removed, but a potent source of irritation—namely, putrefaction—is admitted. Thus the effect of simple incision produces much more serious results in the former than in the latter case. On the other hand, it cannot be denied that septic empyemata often, if not generally, produce much more serious symptoms than aseptic ones. We have had two examples here where putrefaction followed the introduction of the aspirator needle—H. B. (Table II., Case 16) and J. F. (Table II., Case 18), in both of whom high fever and other signs of septic poisoning were present. A. C. (Table II., Case 1), in whom the putrefaction originated from within, was also much more ill than children with chests full of such pus are usually found to be. I have notes of at least three other cases of putrid empyema which proved rapidly fatal.

One of these cases was a boy, aged eight, at University College Hospital, who had only been ill for a month before he was admitted with a chest full of the most offensive pus, and a fluctuating swelling over the second interspace, due to perforation. This was incised; but the boy, who was almost *in extremis* from septicæmia on his admission, died two days afterwards, and it was found post mortem that there was a gangrenous area on the inside of the chest walls corresponding to the upper six ribs, so that the muscles were in many parts dissected, whilst in others they were covered by a sloughy membrane. There was a second point of ulceration besides the actual point of perforation in the second space, and there were four in the third (one of which was complete), four in the fourth (one of which was complete), and one in the fifth space. Such a condition is never met with in aseptic cases.

Another was that of a man aged forty-two years at University College Hospital, whose illness began four days before admission. His chest, which had been previously tapped, was freely incised on the ninth day after the attack, but his temperature and pulse never fell, and he died of septicæmia on the sixteenth day. A small abscess of the lung was found post mortem, the rupture of which had no doubt caused the empyema.

Another case, which I saw with Dr. Thane, was that of a young strumous man between twenty and thirty years of age. His illness began as pneumonia, and when seen the left pleura was distended with the most putrid pus imaginable. Though he improved after the incision, he never thoroughly rallied, and died three weeks afterwards with symptoms of septicæmia and pleurisy on the opposite side.

I mention these cases because they are typical ones of their kind, and are not very uncommon. They should be borne in mind when the assertion is made that putrid cases do as well as aseptic ones. Such results do not, as far as my experience goes, occur in aseptic cases, nor do they ever follow the antiseptic incision if the treatment be carefully carried out.

The causes of putrid empyemata are always, or almost always, gangrenous abscess of the lung, or the introduction of an improperly purified needle, or the rupture of an empyema into a bronchus. In the last instance there will be expectoration of pus from the pleura; but it is an interesting fact that it does not follow that an empyema which is being expectorated will contain putrid pus, the pus sometimes remaining sweet if the communication with the air passages be small and tortuous. Such cases often do extremely well, the expectoration ceasing immediately after incision, and the case following a favourable course. Even if there be a certain amount of smell, I think it is wise to employ the antiseptic treatment for a few days at least, as it sometimes happens, as in the case of abscesses that smell, but are not actually putrid elsewhere, the discharge soon becomes sweet, and the case pursues a typical course. If, however, the discharge continue offensive, a moist dressing, frequently changed (boracic fomentation or an oakum poultice), is much the best dressing from every point of view.

We have thus dealt with the methods to be employed in the primary treatment of an ordinary case of empyema, but a few points remain to be spoken of.

1. If antiseptic dressings are used, they should be continued to the very end of the case. Many a promising case has ultimately become chronic through neglecting this rule.

2. The tube in adults must be retained until the discharge has almost stopped. In ordinary cases, in children, it may usually be removed at the end of a fortnight or thereabouts. But both of these rules are liable to exceptions, especially the latter if the discharge be at all copious. If after the removal of the tube there be signs of accumulation, which will be, not increased discharge showing externally, but a rise of temperature with general malaise and thoracic or abdominal pain, no time should be lost in dilating the sinus and reintroducing the tube. If this be delayed the recent adhesions quickly give way, and much time is lost.

3. As soon as the general health will allow, patients with empyema seem to do better if permitted to get up, the change of position and the movements of the chest apparently aiding the expulsion of the contents of the pleural cavity.

4. Is it wise to employ injections?

5. What is to be done if the case becomes chronic?

The last two questions will be dealt with in the next lecture.

Clinical Lecture

ON A CASE OF

BELL'S PARALYSIS OF CENTRAL ORIGIN.

By W. R. THOMAS, M.D., M.R.C.P.,

SENIOR PHYSICIAN TO THE SHEFFIELD PUBLIC HOSPITAL, LECTURER ON MEDICINE IN THE SHEFFIELD MEDICAL SCHOOL.

GENTLEMEN,—I shall to-day direct your attention to a very interesting case of Bell's paralysis of, I believe, central origin; and for the purpose of comparison I shall picture for you another case of ordinary Bell's palsy from exposure to cold.

The patient suffering from ordinary Bell's palsy, you will observe, when he smiles, smiles but on one side; the paralysed side looks sober and serious. The zygomatics on one side will not contract; whistling to him is an impossibility; fluids will often run out of his mouth; and owing to this utter want of power on the part of the orbicularis oris, he can neither open nor close his mouth properly. Owing to implication of the buccinator, food often accumulates between the cheek and the teeth, and when he blows the cheek becomes much distended from the same cause. An expression of surprise or a frown can only be seen on one side, as the occipito-frontalis and corrugator supercilii are both paralysed. All the muscles of expression, all the muscles supplied by the portio dura of the seventh, are paralysed. The orbicularis palpebrarum cannot contract

Digitized by Google

so the eye is kept open and exposed, and when the patient is told to close the eye he turns it up so that the pupil becomes invisible and nothing but the white is seen, and he thinks that the eye is closed. Even the tensor tarsi cannot contract, and epiphora ensues. Thus the whole right side of the face is an expressionless mask, and yet the left side is full of vivacity, and conveys to you very plainly the workings of the brain.

The next case I have to bring before your notice is a very different one—is one from central origin, and but very seldom met with. The celebrated Dublin physician, Dr. Graves, in his work on Clinical Medicine, says, "I have seen two cases of seizure, evidently apoplectic, in which the paralysis that followed the seizure was seated in the muscles supplied by the portio dura." And, again, Trousseau says, that "when examined with great care, using Burq's dynamometer, these patients invariably display slight want of power in the arm or leg, of which they are not conscious"; and adds in another part, "It is conceivable, therefore, that if a small hæmorrhage occurred in a very limited spot of the pons it would give rise to the symptoms of Bell's paralysis exclusively. But such cases are so very rare that, in the course of a very long practice, I have not yet met with a single instance of the kind."

This patient is a married man, aged twenty-four, a tanner by trade. His family history is good. When seventeen years of age he fell down the cellar steps and injured the left side of his head. Until five weeks ago, for two years and a half he has suffered from epileptic fits, two or three every month. Five weeks ago he fell down in the street in a state of insensibility. He was carried home, soon recovered, but suffered from headache for three weeks. About two weeks ago, one morning his friends noticed that his face seemed peculiar, and laughed at and chaffed him. No treatment whatever was adopted for one week, when he presented himself at the hospital as an out-patient. You see that all the muscles supplied by the portio dura are paralysed, but not completely. The right orbicularis palpebrarum is not much affected, but closes a little later and less firmly than the left. There is also slight epiphora, showing implication of the tensor tarsi. The point of the uvula is turned towards the paralysed side and drawn by its base to the left. The soft palate and arches hang into the mouth, or, in other words, the left side is more arched and roomy. If you apply a weak acid solution to the right side of the tongue, it gives rise to a burning sensation, but no taste, unlike the other side. Hearing on both sides is normal. The occipito-frontalis and corrugator are partially paralysed, and his speech is not natural owing to implication of the buccinator and orbicularis oris.

I should like to draw your attention to the following interesting facts relating to this case:—1. The temporal masseter and pterygoids supplied by the motor branch of the fifth, and the muscles of the tongue supplied by the hypoglossal, are not affected in this case as they are often in hemiplegia, where so frequently the tongue, when protruded, points to one side. This shows that the portio dura only is affected, as in Bell's, wherever the lesion may be. 2. As in facial paralysis with hemiplegia, the orbicularis palpebrarum has not been much paralysed; in Bell's it is. 3. The paralysis of the muscles of the face is not quite complete, and contractility not quite gone, as in hemiplegia. In Bell's the paralysis is generally complete, and electric contractility gone. 4. The paralysis of the uvula and soft palate on the right, and impairment of the sense of taste, show that the great petrosal and chorda tympani nerves are involved, and that the mischief is probably above the part where they are given off. In this case we have not had any ear symptoms whatever, neither intensity of hearing nor obtuseness, so the disease is probably higher than the bony canal. 5. This patient has suffered for two years and a half from about three epileptic fits a month, probably from some central cause. He has not had an attack now for five weeks, but at the end of three weeks from the last attack this paralysis came on. This, to my mind, decidedly points to some central cause, especially when taken in conjunction with the other symptoms. 6. Ever since the attack came on his memory and his mental powers generally have been very much impaired, whereas they were not so before. You will observe that I have come to the conclusion that it is of central origin, not for one reason, but for many—viz., because the electric contractility of the muscles has never been lost, the paralysis has never been complete, the orbicularis palpebrarum has been but slightly paralysed, and the implication of the chorda tympani and petrosal nerves, without any evidence whatever of ear mischief, rather points to central cause; and the epilepsy before and mental symptoms after the attack of paralysis also aid us.

ON INVERSION WITH INFLATION IN THE CURE OF INTUSSUSCEPTION;

WITH A SUCCESSFUL CASE.

BY R. CLEMENT LUCAS, B.S., M.B.LOND, F.R.C.S.,

SENIOR ASSISTANT-SURGEON TO, AND TEACHER OF OPERATIVE AND PRACTICAL SURGERY AT, GUY'S HOSPITAL; SURGEON TO THE EVELINA HOSPITAL FOR CHILDREN.

ACUTE intussusception in childhood must ever be regarded as an exceedingly dangerous condition, but an early recognition of the symptoms will much lessen its dangers, by bringing the case within the range of surgical treatment before adhesions may have taken place, or irreparable damage have occurred to the intussuscepted bowel. It is one of those conditions I would claim as surgical from the onset, inasmuch as the only efficient treatment must be surgical, and it is strictly comparable in this respect to the obstruction occasioned by strangulation in hernia. To my mind, the cases appeal for relief in precisely the same terms as do those suffering from strangulated hernia; and it is grievous to have to reflect upon the valuable time often wasted in palliative treatment, and the lack of promptitude in applying surgical aid, not to speak of the failure to penetrate the shadow of dangerous symptoms which overhangs and enshrouds these unfortunate infants. I have even heard it calmly discussed whether it might not be justifiable to wait patiently till nature might detach the intussuscepted bowel, as if this were a common event or as favourable a result as could be anticipated. I have myself already been in the profession long enough to have witnessed a complete change in the relation of operative treatment to hernia. It is no longer considered a disgrace to fail to reduce a hernia by taxis; and the pounding and crushing which I witnessed as a student have, I trust, now disappeared from surgery. No wonder that, after all the time wasted with hot baths, opium, poultices, and ice, with periodical kneading of the tumour, the dreaded operation, when at last performed, was often unsuccessful. What has brought about this change is the acknowledgment that the danger lies, not in the operation, but in the duration of the strangulation, and in the rough treatment to which the bowel may have been subjected. I look forward to the time when the treatment of intussusception will be in every respect as successful as that for hernia, but this improvement must come about by an earlier recognition of the gravity of the symptoms and a greater promptitude in the application of the means available for obtaining reduction. During the past ten years I have often advised students to disencumber their minds from the general unessential symptoms of strangulated hernia with which word-painters depict in eloquent terms the condition of the patient, and to fix indelibly in their memories three salient signs of strangulation—viz., (1) an irreducible hernial tumour devoid of impulse, (2) persistent vomiting, and (3) constipation. With these signs present, there is no room for doubt, or excuse for delay. There should be no speculation upon what other conditions might give rise to the vomiting and constipation. The surgeon's duty is to concentrate his attention upon the hernial tumour and to relieve any constriction that may be there present before having regard to other possible contingencies. The signs of acute intussusception in children—another form of mechanical obstruction—are, as a rule, equally clear, and may be formulated with equal precision—viz., (1) vomiting, (2) constipation, (3) passage of blood per rectum, and (4) the presence of a tumour to be felt through the abdominal wall and occasionally per rectum. With these symptoms present, there is nothing to gain, but everything to be lost by hesitation or delay. There is a mechanical obstruction present, which must be overcome by mechanical means, and medical treatment in such grave crises is apt to raise in a surgical mind a feeling allied to contempt. The administration of purgatives can only do harm, and anodynes will but obscure the danger by clouding the acuteness of the symptoms. The invaginated bowel is

Digitized by Google

impacted, swollen, and congested. Every hour lessens the freedom of the circulation through it, and the peritoneal surfaces which lie in contact will soon become inflamed and pour out lymph that will glue the introceding bowel to that which surrounds and constricts it. Before this has happened, or at least before the lymph can have so far organised as to withstand gentle traction, surgical interference should have completed its task.

What right have we to stand by with folded hands and watch the efforts of Nature to give relief when we possess such efficient means for cure as are altogether beyond her reach? The prejudice of friends, it is true, is opposed to the means we advocate as essential, nor will they ever give the credit to their surgeon of an unequivocal saving of life, which they would be only too ready to accord to the so-called faith-healers, or such unprincipled men as fill their own pockets whilst affecting to make cures through the aid of the miraculous. From time to time I see cases reported of recoveries from intussusception after the casting off of so many inches, or it may be feet, of intestine; but I read these with pain, for I feel they ought not thus to have been left to recover; and I know their convalescence is seldom permanent, and that there is a prospective early death from stricture at the seat of separation. At best it is only one out of a vast number which can make an imperfect recovery without surgical aid. To hesitate, dally, postpone, is to trifle with Nature. A great, a terrible, and altogether unequal struggle may be carried on to open up a free way from within, when a prompt and simple surgical means from without may easily bring about complete relief.

The means we have at our disposal are—first, inflation with inversion; secondly, should this method of reduction fail, abdominal section, with the object of withdrawing the invaginated bowel; or, finally, when this is impossible, enterectomy may be entertained. I am strongly of opinion that, if the cases are seen sufficiently early, the first of these methods, when properly applied, will seldom fail. The principal object of this paper is to advocate the inversion of the patient during the time inflation is being performed—an addition and aid to the reduction by inflation which occurred to me after failing to reduce an invagination by inflation alone. My experience of the value of inversion during taxis for hernia in children led me to adopt this position as an adjunct to inflation in the case presently to be recorded. Intussusception and hernia, which I have been trying to show have so much in common, are here again brought into parallel lines in the course of treatment. In both the object of the inversion is to cause the intestines to gravitate towards the upper part of the abdomen, and the effect in the case of intussusception will be to straighten the lower part of the bowel, so that the air forced into the rectum will act more directly upon the plug of intestine closing the lumen of the gut. It has been advocated by some to distend the bowel with water in lieu of air, but against this practice I hold a very decided opinion. There are two strong objections to the use of water. In the first place, owing to its weight it exerts much too strong lateral pressure for the intestine safely to bear, and I have found it is easy to rupture the bowel after death by forcing in water. Secondly, should reduction have been accomplished, the contact of a large quantity of water with the lower bowel is apt to increase the tendency to subsequent diarrhœa. Air, on the other hand, is a natural occupant of the intestinal canal, and, whilst its pressure is of the gentlest, its presence excites no unnatural peristaltic action.

The manner in which inflation should be performed is as follows:—An ordinary bellows is connected with a gum-elastic enema tube by means of a piece of rubber tubing, which is firmly wired at either end. Around the base of the enema tube lint should be wrapped, so as to make a conical and air-tight base. The tube is inserted about three inches into the rectum, and the anus closed by the conical plug of lint. Further to guard against the escape of air back through the anus when inflation is commenced, an assistant should press the edges of the buttocks firmly together. It is very important that an anæsthetic should be administered up to the stage of muscular relaxation before the operation is commenced, otherwise the forcible contraction of the abdominal muscles will leave the operator little chance of effecting his object. As soon as anæsthesia is complete, the child should be seized at the ankle and knee on either side, and be raised vertically with his back to the operator, the head being allowed to rest on a pillow. The enema-tube is next inserted, and the anus closed in the way directed. An assistant now places his hand over the tumour in the abdomen to watch the effect of the operation, and the inflation is commenced. The air is at first forced slowly in, and the effect watched through the abdominal wall. The upper part of the rectum or sigmoid flexure will probably be seen to swell up, and the tumour may be noticed to change its position somewhat. If the tumour show little tendency to yield, more rapid action of the bellows may be employed. How, then, are we to know that the intestine has been reduced, and there is no longer occasion to continue the operation? There are three indications of the reduction of the bowel: (1) The assistant whose hand is over the tumour will feel this gradually sink away and be lost; (2) a gurgle of air will at the same time be felt by the assistant, and often heard by the bystanders; (3) the whole abdomen becomes suddenly and uniformly distended and tympanitic. When these signs of reduction have occurred, the enema-tube may be withdrawn and any compressed air be allowed to escape, and the surgeon may leave the case with a feeling of contentment that he has almost certainly saved a life. The after-treatment consists in limiting the diet to milk and ice, and in administering stimulants if there be a tendency to collapse. Small doses of opium may also be given to relieve pain and check any tendency to diarrhœa.

The following is a careful report by Mr. H. W. Drew of a case in which the means advocated were successfully employed on the third day of the intussusception.

Charles T——, aged six years, was admitted into Guy's Hospital, under the care of Dr. Pavy, for abdominal pain and vomiting, on June 22nd, 1885. In the absence of Dr. Pavy he was seen by Dr. Carrington, who, after determining the nature of the case, sent for Mr. Clement Lucas. From the history obtained from the friends it appeared that the child had been well up to and including Friday, June 19th. On Saturday morning, June 20th, he began to complain of pain in the abdomen and sickness. These symptoms continued and increased up to the time of his admission on Monday evening, June 22nd. The condition of the bowels during this period was not positively known. He appears to have gone to the watercloset two or three times between Saturday and Monday, but whether anything was passed was not known. He vomited just prior to his admission and the vomit was yellow. On examination he complained of great pain over the abdomen, but there was only slight tenderness. In the left iliac region, corresponding to the region of the sigmoid flexure, a fusiform tumour, four or five inches in length and about two in breadth, was very readily felt. It was dull on percussion, but not hard. The region of the cæcum was markedly empty and dull on percussion, and the fingers sank down, without resistance, into the right iliac fossa. The rectum was quite empty, but high up there was a transmitted feeling of resistance. The tongue was somewhat furred, but there was not much general disturbance. Pulse full, about 100 per minute, rather irregular; heart-sounds normal; apex-beat in the fourth space half an inch below and to the inner side of the nipple; dulness normal; respiratory system normal. Soon after admission, the child passed per rectum about two ounces of red fluid blood. When Mr. Clement Lucas arrived the patient was placed under an anæsthetic. The house-surgeon commenced to administer chloroform, but as the pulse seemed to fail somewhat, ether was substituted. The patient being fully under the influence of the anæsthetic, an enema-tube connected with a bellows was inserted into the rectum and inflation commenced. A coil of intestine was at once noticed to rise and become distended to the right of the median line, as if the sigmoid flexure or rectum were pushed over by distension. Inflation was continued for about five minutes without further effect, the patient lying meanwhile in the recumbent position. A change was now made in the position of the patient, who was held up vertically with his head downwards. Inflation was again commenced, and in about three minutes Dr. Carrington, whose hand was on the tumour, felt it resolve itself with a gurgle. The operation was then suspended, and a suppository, containing a quarter of a grain of morphia was placed in the rectum. Milk diet with ice was ordered, and the following prescription every six hours: Tincture of opium, two minims; chloroform water, one drachm.—June 23rd: He passed a good night, and this morning is free from pain. No tumour can be felt in the abdomen, which seems rather full, but there is no tenderness. A little more blood was passed, but no fæces. He has taken

Digitized by Google

a pint of milk and seems to enjoy it. Temperature 98·8°; pulse 116. He has not passed any urine since he came in. In the evening, as there was still retention and the bladder could be distinctly felt above the pubes, some chloroform being administered to prevent struggling, a catheter was passed. Twelve ounces of urine, acid, and of specific gravity 1015, were drawn off.—24th: He has again slept well, and this morning complains of no pain. There is no swelling of the abdomen. He has had no motion, and there is still complete retention of urine, which has to be drawn off by the catheter. No vomiting. Temperature normal. Ordered: tincture of belladonna, ten minims; camphor water, half an ounce; every six hours.—25th: Early this morning he passed a small quantity of fæcal fluid. He slept well, and is comfortable. Complete retention of urine still continues. The urine was drawn off by catheter this morning without chloroform, and fourteen ounces were evacuated. It was acid, clear, and of specific gravity 1012. He takes his milk readily.—26th: He had another good night, and continues cheerful and free from pain. There is still complete retention of urine, but this morning he passed a very dark liquid stool containing only small pieces of solid matter, the largest about the size of a pea. Temperature normal; pulse 92. Twelve ounces of urine were drawn off about midday. He is taking custard to-day. —27th: He has again passed a good night. He complains of no pain, but the catheter was required again to relieve his bladder. The bowels have not acted to-day.—28th: He continues free from pain and takes his food well. In the afternoon he passed urine naturally for the first time since the operation. In the evening the bowels acted again, and much more naturally; he passed about six solid pieces, the largest the size of the little finger, greenish-yellow and firm. Ordered farinaceous diet with milk.—29th: After passing a good night he emptied his bladder naturally. The bowels acted well in the afternoon. In the evening he sat up for the first time since the operation.—30th: His bowels acted well again this morning, and he was allowed to get up early in the day—July 1st: He is running about the ward apparently quite well.—2nd: He continues well, and went out to-day.

It will be observed that the vomiting and abdominal pain which commenced on Saturday morning continued without relief until the operation on Monday evening. The condition of his bowels was not known with any certainty until after his admission into the hospital. All that the friends were able to state was that he had been two or three times to the watercloset, but whether anything was passed was not ascertained. Among the children of the poor little attention is paid to the condition of the excreta, and the sanitary arrangements are often such as to prevent any examination of the motions passed. Soon after his admission into the hospital, however, he passed blood per rectum without any natural motion, and, a tumour being felt in the abdomen, the diagnosis of intussusception was not doubtful. The obstruction was overcome by combining inversion with inflation, after inflation alone had failed. The tumour was felt to disappear under the hand, and the intestine, becoming unravelled by the *vis a tergo* allowed air to pass up beyond the seat of obstruction. From this time the vomiting ceased, and the only trouble that followed was due to retention of urine, which is a not uncommon complication of abdominal operations. His diet was restricted for several days to a pint of milk in twenty-four hours; the bowels acted on the morning of the third day; and, when the bladder began to empty itself naturally on the sixth day, there was no longer any cause for anxiety.

Nothing could have been more satisfactory than the result of our treatment in this case; but had we failed to reduce the obstruction in the manner described, we had other resources at our command. It was our intention, under such circumstances, to have opened the abdomen on the lines *alba*; to have sought for the tumour, and, having found the intestine at the point of invagination, to have exerted gentle traction, thus employing what might be described as *vis a fronte* for the restoration of the bowel to its proper position. Had we been again baffled in our attempts to restore the intestine to its natural condition, we should probably have proceeded, if the condition of the patient had permitted, to perform resection of the intestine. This would be performed only as giving a last chance; and I am strongly of opinion that, with a better recognition of the symptoms characteristic of intussusception, it will seldom be necessary to resort to this extreme measure, or even to that of opening the abdomen. It is sometimes pleasant to look back on the experience of former years, and these cases possess an especial interest for me, inasmuch as the first case I ever published and the first printed article to which my name was ever attached was, "A Case of Intussusception cured by Inflation," which appeared in THE LANCET for 1870, vol. ii. page 183.

"POLITICAL MANIA" IN CONJUNCTION WITH PARALYSIS AGITANS.

BY ALFRED MANTLE, M.D.

THE following particulars of a case of "political mania" in a respectable working man, the subject of paralysis agitans, may be interesting, since attention has recently been drawn to this form of madness in the columns of THE LANCET.

W. S——, aged sixty-nine, has been under my observation five years. He never had any serious illness until ten years ago, when symptoms of tremor appeared. He has always been of strictly temperate habits, and was formerly a carrier by occupation, but latterly worked at a colliery. He is the eldest of eight children. His father, who always took a lively interest in politics, died of senile decay. His mother died of consumption. Three sisters are living, and healthy. His four brothers are all healthy, with the exception of the youngest, who is now suffering with the same disease—paralysis agitans. There is no history of any other member of the family having any nervous disease, but all take an interest in politics. My patient is a well-educated man for his position in life, and has always watched the political world with a considerable degree of enthusiasm. When a Conservative working-man was supposed to be a being scarcely in existence, and only rarely heard of, let alone seen, my patient, although living in a remote corner of the country, was a staunch supporter of Conservative principles; and, unlike the majority of politicians, he has never deviated from the path of Toryism, but has always remained true to the cause he first espoused. For seventeen years he has taken a daily paper and closely watched the political party in power, but it was not until the election of 1874 that he became an extraordinary political enthusiast. At this time he was most anxious for the Conservatives to be in power, and, the result of the elections being such as to enable Lord Beaconsfield to form a government, his political craze became more and more intensified. It was noticeable then that he was more easily agitated when anyone advanced an opinion contrary to his own. A few months afterwards he had tremor in the right hand, the arm becoming likewise affected after a short time. He gave up work for nine months, with no improvement. His political ardour was as strong as ever. He attempted work again, but after working for some four or five months he was obliged to give up, the left leg becoming affected with tremor. The disease continued to progress slowly, and at the end of two years all the limbs were similarly affected.

The patient's interest in politics, in spite of so sad a disease, instead of diminishing, has steadily increased, and at the present time, when sometimes he is quite prostrated by the sufferings and discomfort such patients have to endure, he will make a determined effort every morning to learn the political news revealed in the daily papers. On account of the tremor being so general, and having the constant desire to change his position, suffering as well from excessive heat, this is only accomplished under the most trying circumstances. Anything else save politics receives little or no attention from him; and his one topic from morning to night, if he can get anyone to talk with him, is that of politics. Should anyone disagree with him, he is very soon in a great state of mental agitation, which results in an exacerbation of the tremor, terminating in great prostration. His wife, knowing that his first question to a stranger is to discover his political creed, makes it her business to ask anyone who may hold different opinions from himself to be Conservative *pro tem.*, in order to prevent an exacerbation of the tremulous symptoms and consequent prostration. I have always made the same request to a locum tenens seeing him in my absence. One marked feature is the opinion he entertains of his opponents, denying them any principle whatsoever. He has a particular

Digitized by Google

aversion to the late Prime Minister, and does not hesitate to say he would rejoice to hear of his decease. He thinks it is utterly impossible for Mr. Gladstone to get to heaven; and, although holding strong religious views, he is sure he could not enjoy that new country were he conscious of the ex-Premier being there also. Upon my jocosely, though thoughtlessly, remarking one day, on hearing this statement repeated, that I thought both Mr. Gladstone and himself would reach heaven, and that it might possibly happen he would carry the former's harp, he became terribly excited and offended with me for suggesting such a possibility.

A few months ago, when my patient thought the late Government was making some terrible blunders and was impatient for a change, his disease became much exacerbated, and there was great prostration, with retention of urine, lasting for a fortnight. I quite thought he would not recover. Day by day he asked to be informed of the latest news. Being told that Mr. Gladstone had resigned, his face lighted up with joy, and it would be incredible to anyone who had not witnessed it to believe the change in his condition from that time. He soon regained strength of mind and body, and has taken an anxious interest in the late General Election. The excitement in the early part of it, when the Conservatives met with such marked success, was too much for him, causing great prostration and compelling him to keep his bed for several days. When the results were known later on, his disappointment was very marked, for he had expected a great Conservative success. I have spoken of his hatred of the Liberal leaders, but should not omit to remark upon his great attachment for the Tory chiefs. The late Lord Beaconsfield he adored, and most acutely felt his death, telling me it was a greater blow to him than the loss of any relative.

The patient's brother, aged fifty, whom I have mentioned as suffering with the same disease, lives some fifteen miles distant, and was a clerk by occupation, but is now a publican. He has not come under my immediate observation. The symptoms in his case first appeared six years ago, about the time of the General Election of 1880, when he was taking a more than ordinary interest in politics. They are not so fully developed as in my patient, though all the limbs are affected with tremor. From all accounts, his mind has suffered more than in the case of his brother, and he endeavours to live a secluded life, although taking a great interest in politics. It is a remarkable fact that he holds entirely antagonistic views to those of his brother, and is a great admirer of Mr. Gladstone. In consequence of their opinions being so opposed to each other they do not visit, this probably being the wiser course to adopt.

Stanley, Durham.

ON THE

PALLIATIVE AND RADICAL TREATMENT OF THE OBSTRUCTING PROSTATE.

By REGINALD HARRISON, F.R.C.S.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY, AND LECTURER ON CLINICAL SURGERY IN THE VICTORIA UNIVERSITY.

It is now upwards of four years since I brought under notice my views and practice as to the prevention and palliative treatment of prostatic obstruction,[1] and eighteen months since I published a communication[2] illustrating the employment of prostatotomy in more advanced and otherwise irremediable forms of this affection. It is to these subjects I propose again referring. Though the proportion of persons suffering from an obstructing prostate is not inconsiderable, it is a matter of satisfaction to me to know from my own observations, and to hear from others who have been good enough to communicate with me, that there are grounds for believing that it has been sensibly diminished by the more general employment of the simple means advocated in my first paper, and that hence the necessity for adopting the more radical measures which form material for description in the second communication referred to has been, and is still further likely to be, sensibly reduced. Still, so long as cases of the latter kind present themselves, so long will it be necessary to carefully consider the various proposals urged for their relief.

It is hardly requisite to point out how frequently we find large prostates in persons who have been, as far as it is known, but little inconvenienced by them, the explanation of this immunity from symptoms being found in the fact that the growth in no way interfered with the outlet from the bladder. In this conservative process there is much that may be imitated by art; and as the regular expulsion of urine from within outwards is capable of preventing obstruction by the formation of grooves or channels in the hypertrophied mass, so in like manner may the same condition be brought about by the introduction of a suitable instrument along the passage which is threatened with extinction. It is important to notice how slight is the prostatic barrier in some of these instances, but yet how complete is the obstruction which is thus occasioned both relatively to the act of spontaneous micturition and to the introduction of an instrument to relieve it. When we consider how extremely limited physically is the nature of the obstruction in many of these cases, it is not difficult to understand how readily this state may be remedied by the timely adoption of mechanical means. How easily the mere outlet of the bladder may be improved in some instances of obstruction by a large prostate is shown by the undoubted success which frequently followed the practice of Mercier in making a linear incision through the prostatic bar, and more recently by the means advocated by Gouley, where no more than a small portion of the obstruction is punched out by an ingenious instrument contrived for this purpose. Of both of these operations I have had sufficient experience to enable me to conclude that, as a rule, the amount of tissue it is necessary to divide or destroy for the purpose of permanently improving the outlet from the bladder is comparatively small. It is, however, not to be implied that, because the orifice of the bladder is mechanically improved so far as relates to the mere act of letting urine out or an instrument in, the power of spontaneously discharging urine naturally follows upon this; on the contrary, it frequently happens that under the strain of months or years of unaided micturition the muscular power of the bladder becomes sensibly and permanently weakened, or the power of expulsion completely disappears, never to be regained. Hence it becomes, in all cases of impeded micturition, of the first consequence that every means should be taken to avert a catastrophe which by no means ceases with the mere inability to expel urine from the bladder. From the observation of a number of cases of this kind, it seems clear that when the prostate in its growth commences to obstruct micturition the hypertrophic process increases proportionately with the efforts of expulsion. This is only to be expected in a part which largely consists of involuntary muscular fibre, and is necessarily more or less involved in the sphincter action of the apparatus. In illustration of what preventive treatment can do, I will select a typical case of the kind which has been under observation for some years.

In 1881 a gentleman of sixty years of age consulted me for an irritable bladder. Not only was there unnatural frequency in passing urine, but the act had lost its normal characteristics, for, instead of the urine being expelled in a stream, it seemed rather to ooze from the penis. Though an examination of the prostate from the rectum revealed but little amiss with the gland, further investigation determined—first, that there was a considerable obstruction within the prostatic urethra; and, secondly, that the bladder was commencing to lose its power. Under these circumstances I advised the patient to introduce a soft instrument into his bladder daily until further instructed. In the course of three months he was practically well, and, beyond passing his instrument occasionally for his own satisfaction, he has remained so. Can it be doubted that this marked change was due to the use of the instrument? What would the patient's condition have been within six months had nothing of this kind been done?

In an experience of this kind, which has not been inconsiderable, I think I may say that where there exists any mechanical obstruction to the escape of urine along the urethra from the bladder, I have never known any harm come when an instrument adapted to the particular case has been selected and is properly used. Where these conditions are not complied with, it is not remarkable that the results have been disappointing. On the other hand, the evidence of patients themselves as to the immediate and

Digitized by Google

permanent advantages attending the employment of mechanical means in the earliest stages of prostatic obstruction is sufficiently ample to render further allusion to this aspect of the question unnecessary.

I will now proceed to notice the treatment employed in those cases of prostatic obstruction where the condition of the patient appeared hopeless of relief by such palliative measures as the use of the catheter. I have now operated under these circumstances in four different ways, which I will briefly illustrate.

First, by a removal of more or less of the obstructing prostate by an incision from the perineum. In two instances where this was done both patients are now alive and well, after intervals of seven and four years, having previously suffered from the most serious forms of prostatic obstruction.

Secondly, by perineal incision and section of the bar, and by the subsequent use of a proper drainage-tube. Let me take two illustrations from amongst several where this was done. In June, 1883, I reported[3] one of my earliest cases where I had thus operated. The patient has since remained under observation, has discarded his catheter for over a year, and is perfectly well. In August of the present year I met a man (J. B——, aged seventy-three) in the street carrying a heavy load on his back, who I recognised as an old patient of mine upon whom I had performed median prostatotomy. I questioned him, and found that he was quite well and had never used the catheter since he left my care. The circumstances of this case, which has not been published, are briefly these: The patient was sent to me by Dr. A. Barron. He had a large prostate, required constant catheterism for retention; the instrument was difficult to introduce, and serious hæmorrhage frequently took place. For three weeks he was treated in various ways, but with no benefit. His desire to urinate and his strainings were incessant, and nothing appeared to give any relief. In February, 1884, he underwent median prostatotomy, and wore one of my tubes for seven weeks; the perineal wound closed, and he shortly left the infirmary with the result I have already mentioned. I should add that I have recently had an opportunity of passing a full-sized bougie, when not the slightest hitch was experienced. This man's present condition is a remarkable contrast to what it was previously.

Thirdly, by the permanent retention of a perineal tube with a suitable tap. This has twice been resorted to. In both of these instances it was only intended to use this apparatus for temporary purposes after median prostatotomy, as in the second class of cases, but at the patient's desire the tube was allowed to remain in. In one of these instances the patient wore the tube for three months in the infirmary, and then left to reside at a distance from Liverpool. I have not been able to hear further of him. The second case was where the patient wore the apparatus nearly three months, when he removed it on finding the power and function of the bladder returning. The opening has closed, and when he was last seen by me, nine months after the operation, he was quite well, but he still used the catheter daily. I believe he could do without the latter instrument, but he had suffered so much from retention and difficulty in getting an instrument into his bladder prior to the operation that I was not surprised at his taking this precaution.

I should just say one word on the apparatus used. It consists of my ordinary bladder drainage-tube, as made for me by Mr. Wood, 81, Church-street, Liverpool, to which is attached a piece of rubber tubing, about 2 ft. long, terminating in a small stopcock; the perineal tube is retained by a modified T-bandage, whilst the end of the tubing is looped into an ordinary belt which the patient wears. All he has to do is to let down the end of the tubing and turn the stopcock when he requires to pass urine. Within three weeks both of the patients I have just mentioned were up and going about the wards as usual. I have frequently had patients up and about within ten days from the operation.

I have sometimes been asked whether I do not find that the urine leaks through the wound by the side of the tube. If the wound is properly made this is not the case. It sometimes happens that after the perineal tube has been worn for three or four weeks the urine is suddenly propelled along the side of the tube, and I have known some even escape along the anterior portion of the urethra. This is a sure indication that the tube may be entirely dispensed with, and that the urethra is prepared to resume its normal function.

Fourthly, by prostatic puncture, without incision, and the retention of the cannula made for me by Messrs. Krohne and Sesemann. Atrophy of the large prostate has followed this proceeding.

A study of the cases I have arranged under these four headings will, I think, justify me using the term "radical cure" in connexion with the treatment of advanced forms of prostatic obstruction. I will now, in conclusion, turn to the other side of the picture, and refer to those cases where I have failed to obtain the results I could have desired. I have now operated over twenty times—a number sufficiently large for the purpose of drawing some general conclusions which seem to me of value in connexion with this subject. Not a single instance has yet happened to me where I either regretted having done the operation, or directly or indirectly connected the death of the patient with the proceeding. In two instances only, so far as I know, did the patients die; one three weeks after the operation, and another four. Both of these patients lived longer and far more comfortably than they would otherwise have done, and had nothing to regret in what was undertaken for them. Both patients showed after death a condition of the urinary organs beyond repair; both showed the damage that long-continued back-pressure of obstructed micturition is capable of effecting, and to this extent was a cause for regret that more perfect mechanical measures for relieving this back-pressure had not been earlier applied. Both of these cases, however, served to teach how the mechanism of median prostatotomy, as already described by me,[4] might be improved, for both shewed that in some instances the form of the prostatic bar was such as to render it wellnigh impossible to divide it adequately, as in lateral lithotomy, from before backwards: it is necessary sometimes to use a long curved probe-pointed bistoury, passed within the bladder from the perineal wound, and to divide from within outwards. Of the importance of this I have since been able to satisfy myself in practice. Only in these two instances, and a third, where I removed almost the whole of a carcinomatous prostate, the patient living in comfort for ten months, and being able to return to his work, did death follow, so far as I can ascertain, either shortly afterwards or more remotely, any of the proceedings I have just referred to under the headings of prostatectomy, prostatotomy, and perineal drainage. The improvements which have recently been made in the drainage of bladder wounds, the arrest of hæmorrhage, and in the use of antiseptics, bid fair not only to extend our means of relief in directions which previously seemed hopeless, but to lessen the high mortality which appears to have attended some operations for stone and allied affections of the urinary apparatus.

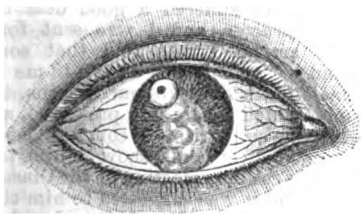
A CASE OF

CYSTICERCUS OF THE ANTERIOR CHAMBER.

BY RICHARD WILLIAMS,

SURGEON TO THE LIVERPOOL EYE AND EAR INFIRMARY, AND OPHTHALMIC SURGEON TO THE ROYAL ALBERT EDWARD INFIRMARY, WIGAN.



F. B——, a collier, aged twenty-two, was admitted into the Wigan Infirmary on Sept. 12th, 1885, and was first seen by the senior house-surgeon, Dr. J. Buchanan, to whom I am indebted for the notes relating to the earlier period of the case, and who found him suffering from iritis of the right eye. Three days later this diagnosis was confirmed by myself, and the case was treated with atropine in the ordinary way. The patient said that three or four weeks before admission his first symptom had been pain in the eyebrow, followed two days later by "inflammation" and failure of sight. Some days the pain was so severe that he had to take to bed. Previous to the attack his vision had always been good. There was no specific history.

On admission the iris was discoloured and the pupil apparently fixed, the officinal solution of atropine producing no dilatation. On Sept. 21st a whitish mass was noticed in the lower part of the anterior chamber, and immediately above, rather behind and to the inner side of this mass, a small round

Digitized by Google

vesicle about the size of a small bead was observed. It was transparent and contained a whitish nucleus. Two days later the vesicle had somewhat changed its position, and was seen to have a tremulous motion. On Sept. 28th it had moved upwards and the exudation covered the pupil, so that the patient's vision amounted to faint perception of light. The following day the patient was again seen by me after my return from a fortnight's holiday, and the eye presented the appearance shown in Fig. 1. There was considerable perikeratic injection and lacrymation. The pupil was hidden behind a mass of whitish substance, which might easily have been mistaken for lens matter after a needling operation. Above this heap at the outer and upper corner of the anterior chamber, resting on the iris, was seen a small, round, transparent body, with a regular outline and a yellowish speck in the centre. On carefully watching this

FIG. 1.

body, its walls were seen to have an active wavy movement every now and again, and the diagnosis of cysticercus was now made. It was also noticed that during the more active movements a whitish cloud passed apparently through the vesicle, so as temporarily to hide the nucleus in the centre. On Sept. 30th some of my colleagues at the Eye and Ear Infirmary had an opportunity of examining the patient, and all agreed in the diagnosis. The cyst had now dropped to the lower and outer angle of the anterior chamber, so that altogether it had made an excursion of nearly the whole of its circumference. Two days later (Oct. 2nd) the movements of the entozoon were much less marked, but still quite visible with the aid of a magnifying lens, and the exudation had considerably diminished. The general symptoms were, however, on the increase, and the pupil was undilated.

The patient was now placed on the operating table, and

FIG. 2.

some cocaine having been instilled, a linear incision was made with a Graefe's knife in the lower part of the cornea, just below the cysticercus. The incision was made rather quickly, in the hope that the vesicle would escape with the aqueous. My expectations were more than realised, for it shot out with considerable force, and was found on the pillow near the patient's head. The iris prolapsed into the wound and could not be returned. I therefore cut off a small portion, and the eye was dressed in the usual way. The eye made an excellent recovery, and now (Nov. 20th) V = $\frac{6}{6}$, there being only a slight difference in clearness between this and the other eye. The small gap in the iris and one or two small pigmentary deposits on the lens are the only remaining ill effects. The cyst, on being picked up, collapsed, but the cyst wall was put under the microscope by Mr. Barnard, the junior house-surgeon, and presented two groups of hooklets, of twelve each, one of which is shown in Fig. 2. The anterior chamber, as shown in Fig. 1, was the seat of a considerable quantity of a peculiar-looking exudation, which, I believe, was not at all inflammatory, but was probably a coagulable liquid thrown out of the vesicle itself. Two things lend probability to this supposition. First, the shape and position of the exudation—immediately underneath the vesicle; and, secondly, it diminished in quantity with the diminished activity of the animalcule, although the general symptoms of inflammation were rather on the increase.

The extreme rarity in this country and in France of cases of entozoa of the organ of vision imparts to them quite an exceptional interest, and every practitioner is under an obligation to record whatever experience he may possess of so interesting and destructive a disease. De Wecker says (Traité Complet) that no case of cysticercus of the anterior chamber has ever been recorded in France, and in 100,000 patients he only met with two cases of the animalcule in the vitreous. On the other hand, the disease is comparatively common in Germany, for Alf. Graefe detected the entozoon eighty times in 80,000 patients. The reason given for this great difference in frequency is the custom of eating raw meat in the latter country. In the British islands, Mackenzie, Windsor, and Teale have each reported a case. In the district in which my patient lives the disease cannot be common, for this is the only case that has come under my observation, nor do I know of anything in the patient's habits or circumstances to account for the appearance of the disease in him.

CASE OF POST-MORTEM HYPERPYREXIA.

BY T. EDGAR UNDERHILL, M.B., F.R.C.S. EDIN.,
SURGEON TO THE GUEST HOSPITAL, DUDLEY.

THE subject of post-mortem thermometry is one that has at various times attracted the attention of many observers, and different theories have been put forward to account for the remarkable elevations of temperature which are occasionally found to exist after death. Wunderlich says: "In many cases of disease, even such as are not febrile in themselves, during the last hours of life the temperature rises enormously, generally by a sudden spring to over 41° C. (105·8° F.), or even above 44° C. (111·2° F.) They are generally diseases in which the central nervous system is seen to be implicated, and generally severely so before the rise of temperature. Tetanus in particular pursues such a course, and so do epilepsy and hysteria when terminating fatally; and so also inflammatory affections of the brain and medulla spinalis, as well as injuries of the upper part of the medulla." He adds: "The remarkable phenomenon of post-mortem rise of temperature which sometimes occurs in cholera, but especially in cases of disease which have terminated with hyperpyretic temperatures, is based on two causes. When death occurs, the cooling that goes on by the introduction of air (in respiration) and by perspiration comes to an end, whilst the warmth-producing processes of the economy are not so immediately terminated; and new sources of warmth are opened after death by changes in the substance of the muscles and post-mortem decomposition—two sources which are foreign to the living body, and which are sufficient to maintain the corpse for a short time at an equilibrium of temperature against the losses of heat it suffers, and sometimes even to raise the temperature a little." According to Huppert, and also according to Fick and Dybkowsky, the reason for the elevation of temperature after the cessation of the circulation is to be found in the setting free of heat during the stiffening of the muscles on the coagulation of the myosin. At the same time, with the cessation of the circulation, the circumstances governing the giving off of heat change, the exchange from one layer of the body to another is accomplished by conduction without the intervention of the circulation. In the following case there was no evidence of any implication of the central nervous system or any visceral lesion as a cause of the hyperpyrexia, the slight delirium which was present in the pro-agonistic stage being apparently a result of that condition. Death occurred at an hour when in the diurnal fluctuation of temperature the mercury is generally at its lowest, and in spite of antipyretic medicines, which only resulted in profuse diaphoresis.

S. P——, aged thirty-five, a strong, healthy woman, was

Digitized by Google

delivered on Nov. 5th, 1885, of a living male child. Labour was natural, and she progressed most favourably afterwards, speedily becoming convalescent. On Dec. 3rd she came to consult me about a small tender swelling in the left breast, close to the nipple. Milk was abundant, and she was nursing from both breasts. I applied some liquid extract of belladonna to the left breast, and recommended her to stay in the house for a few days.—Dec. 6th: There was every appearance of a small mammary abscess, though fluctuation was indistinct. She complained of shivering. Was ordered to bed, with quinine every two hours.—7th: Much better. Temperature normal. No pain in breast. Fluctuation more distinct.—8th: Slight rigor; skin moist; no pain; abscess about the size of a small nut, and pointing close to the nipple. I suggested making an incision, but she preferred to let it take its course.—9th: Patient same as yesterday. Skin warm and moist; abscess had not burst. I omitted to use a thermometer, as there appeared to be no higher temperature than I should have expected from the state of the breast. No evidence of disease in any other organ. In the evening her husband came to me and said she complained of feeling very hot, but was in no pain. I ordered fifteen grains of salicylate of soda and fifteen grains of citrate of potash every two hours.—10th: Sent for at 4 A.M., but on my arrival found the patient dead. Her mother told me that she had remained in the same condition as when I last saw her, merely complaining of feeling very hot, till about 3 A.M., when she became slightly delirious, and died a few minutes before I arrived. On placing my hand on the body, I found it still very hot, though the skin was moist, and her night-dress was saturated with perspiration. I introduced a thermometer into the right axilla, and the mercury rapidly rose to 110·2° F. Thinking there might be a mistake, I shook the index down and took the readings again, but with the same result. After fifteen minutes I requested patient's mother to ascertain the temperature, and she found it exactly the same. I waited for more than an hour, and removed the bedclothes so as to expose the chest and allow cooling to proceed more rapidly, and the mercury then rose to 103·8° F.

I regret that I omitted ascertaining the temperature on the two days preceding death, though I am of opinion, from a manual examination, that there was no condition of hyperpyrexia existing when I last saw her alive. The case is a most unfortunate one, as there was no evidence of disease in any organ which would lead one to suspect a fatal termination, and consequently I expressed a favourable prognosis only a few hours before death took place.

A CASE OF TUBAL PREGNANCY.

By ALEX. HAY, M.D.

FROM the rarity of cases such as the following, I have deemed that a perusal of the details may be of interest.

On December 23rd, 1883, I was called to visit Mrs. R——, a young married woman, aged twenty-four. I found her in bed, lying on her back with her knees drawn up, slightly feverish, and complaining of considerable pain all over her abdomen, but especially over the left side. There was slight tympanites and tenderness on pressure. She told me that she had no family, but that she had not menstruated for four months, and had felt quite well until the day previous to calling me in. She attributed her present illness to fatigue which she had just undergone while nursing her sister-in-law, who had been very ill. On examining her abdomen, I discovered a tumour about the size of the fist in the left iliac region, manipulation of which caused some pain. I called her attention to its presence, but she said she had never felt it before. It was freely movable, and presented to the touch the feeling of a round solid mass, but on more minute examination I convinced myself that there was an off-shoot from its inner border. I then examined per vaginam, at the same time pressing the tumour down from above; but, as no impetus was felt at the os uteri, the idea immediately occurred to me that I had to deal with a case of tubal pregnancy. I ordered her an opiate and to apply hot fomentations.

I saw the patient the next day, and, discovering nothing to make me alter my opinion, I resolved to have a consultation, and accordingly, on Dec. 26th, called in Dr. Stirton, Professor of Midwifery in the Glasgow Royal Infirmary School of Medicine, telling him what I believed to be the nature of the case. He examined the patient carefully, and at first was inclined to agree with me in my diagnosis; but after passing the uterine sound he came to the conclusion that she was not pregnant, but was suffering from ovarian disease, and in this opinion he was strengthened by the fact that there were present none of the usual signs of pregnancy—no sickness, no mammary secretion, and no deepening in colour of the areolæ; and, moreover, during his examination per vaginam, there was discovered a discharge of blood which had the appearance of being catamenial. At the same time he stated that I might be right after all, that probably the wish on his part might be father to the thought, and advised me to watch the case, as time would clear the matter up.

I continued to visit the patient daily, each time making a careful external examination. During the night of the 29th she had suffered a good deal of pain of a bearing-down character, and I was sent for early next morning. On arrival I was told that something had come away, and when this was shown to me I found it to consist of a male fœtus of quite four months, with placenta and membranes, which I carefully preserved, and have the specimen before me as I write. I communicated the result to Dr. Stirton, and afterwards showed him the specimen. He mentioned this case at a meeting of the Glasgow Southern Medical Society, and it was suggested to him there by one of the members that there may have been a double uterus; but in this view neither he nor I coincided, because, in the first place, the tumour was quite distinct from the uterus, as evinced by no impetus being conveyed to the finger placed against the os when pressure was applied externally; and, in the second place, with the expulsion of the fœtus the tumour quite disappeared, and on passing the sound it was found to be like a virgin uterus. My own opinion is that it was purely a case of tubal pregnancy, that the offshoot which I felt at first must have been the lower extremities, and that the irritation set up by the previous exertions of the patient, the passing of the uterine sound, and the frequent manipulation, had caused contraction of the pouch formed in the Fallopian tube and the subsequent expulsion of its contents.

The patient made a good recovery, no untoward symptoms arising. She left this district some time ago, but being anxious to know somewhat of her subsequent history I instituted inquiries about her, and learned that she had given birth to a full-grown male child on Aug. 21st last, and that the same kind of tumour had again presented itself in the same region, and had remained there until between the third and fourth month of pregnancy, when it suddenly disappeared, receding (presumably) into the uterus, and remaining there this time until the full term of utero-gestation, as the sequel showed, thus resembling a case reported before the Obstetrical Society of London on Oct. 7th by Mr. E. F. Grün.

The Grange, Maryhill.

NOTES ON SPRING HEALTH-RESORTS.

By W. E. BUCK, M.A., M.D. CANTAB.

THE question of where to send patients after wintering on the Riviera is often a difficult one. They are only too apt to hurry back to England at the most trying time of the year, and so undo all the good done; after which they will maintain that, "though the Riviera does temporary good, the benefit of wintering there is but transitory."

There are two spots in the Maritime Alps which seem to me particularly well suited to be half-way houses on the road to England—namely, San Dalmazzo di Tenda, and the Certosa di Pesio. Of the two, San Dalmazzo appears to offer the most advantages. A large building, formerly a convent, has been turned into an hotel or *pension*, where, if desired, hydropathy can be indulged in. The management of the establishment is excellent, and the prices are reasonable. It is situated on the southern side of the Col di Tenda, in the valley of the Roya, and at about 2000 ft. above the level of the sea. The surroundings are most picturesque. The air in May and June is light and fresh, but not cold, and less exciting than the air of the Riviera. San Dalmazzo is on the high road to Nice, but is nearer to the station at Ventimille, which may be reached in six hours by a good

Digitized by Google

carriage-road. The establishment opens on April 15th. The Certosa di Pesio is another charming resort. It is cooler than San Dalmazzo, being rather higher and situated in a valley on the north side of the Maritime Alps, and does not open till the middle of May. It can be easily reached from the Riviera, *viâ* Genoa, Savona, and Mondovi; the Certosa is about three or four hours' drive from the last-named station [illegible].

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, Lib. Ir. Proœmium.

ST. THOMAS'S HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. SYDNEY JONES.)

FRACTURE of the base of the skull is a severe injury, and when complicated with numerous other fractures, notably of the bones of the face, proving the great severity of the violence applied to the head, is usually fatal. Fractures of the bones of the face, including the superior maxilla, the nasal bones, and also the inferior maxilla, are uncommon, and the injury usually terminates fatally. In this case there was in addition a Colles' fracture of both arms, one of them compound. In a large number of cases of fracture of the base of the skull optic neuritis develops during the course of the injury, but, if unattended by symptoms of general meningitis, does not appear to indicate a bad prognosis. The case of dislocation of the knee is an example of one of the commoner dislocations of that joint (a lateral one), and is interesting from the fact that such injuries are rare.

CASE 1. *Fracture of the base of the skull; separation and fracture of the bones of the face; Colles' fracture of both forearms; strabismus and optic neuritis; recovery.* (From notes by Mr. SHERRINGTON.)—The patient, a coal-porter, aged thirty, was admitted on March 27th, 1884, having fallen twenty feet into a coal-bin half an hour previously. He had been unconscious for a short time after the fall. There was a wound of the upper lip, extending half way to the nose from the mucous margin; there was also a contused wound over the bridge of the nose, at the bottom of which bare bone could be felt, and running vertically across the base of it a line simulating fissure of the bone. There was much ecchymosis of the cellular tissue of the eyelids of both eyes, and on the right side it was present under the ocular conjunctiva. There was slight hæmorrhage from the mouth, nose, and left ear. The lower jaw was fractured in two places, the two lines of fracture being one on either side of the symphysis, and between them included a fragment containing the two central incisor teeth and their bony sockets. This fragment was lying loose and nearly completely free under the tongue. It included more of the inner than of the outer plate of the alveolus. The two halves of the jaw moved freely against each other with crepitus. The upper jaw was also fractured, the two halves being separated one from the other and easily moving against each other, the range of movement being, however, limited to about the eighth of an inch. There was an impacted Colles' fracture of the left arm with some comminution of the lower fragment; also a Colles' fracture on the right side, with two small wounds above the wrist in front, one of which communicated with the fracture. In both fractures the typical displacement was well marked. The man was suffering from shock, cold and shivering, but conscious. Pulse 112. Hot bottles were applied to the feet. The wound of the forearm was dressed antiseptically, and after extension of each forearm to restore the parts anterior and posterior plaster-of-Paris splints were applied.

28th.—Gutta-percha splints for the upper and lower jaw applied. The right forearm was dressed and found that the wound was almost healed. A gutta-percha splint was applied to the under surface of the lower jaw. The right pupil was smaller than the left and acted to light; the left pupil did not respond well.

14th.—The eyes were more fully examined, and the following note made:—Nearly complete paralysis of the right external rectus; other movements normal; secondary squint very marked. Left eye movements normal. The pupil has no direct action to light; indirect action good; it is considerably larger than the right pupil. Left optic disc somewhat pale. Veins normal. Arteries somewhat diminished in size. There is slight haze of the optic disc and central portion of the retina, the fovea centralis being very easily seen. The right fundus appeared normal; there was some doubtful haze about the margins of the disc. It was supposed that in all probability there had been direct injury to the left optic nerve, possibly by fracture through the optic foramen.

16th.—The appearance of the left fundus resembled that of embolism of the central artery, the arteries being diminished and there being a good deal of haze. The blindness was first noted about four days after admission.

22nd.—Yesterday the splints on the left arm were shortened, so as to leave the fingers free. A week ago those on the right arm were similarly reapplied. The wounds are completely healed. The fracture of the upper jaw is quite firm and in good position; the splints are discontinued. A fissure, however, exists in the posterior part of the hard palate, about half an inch long, through which fluid passes into the nose. There is some underlapping of the lower jaw due to the loss of the central portion, and the union is not firm. The pieces are fixed by silk fastenings round the bicuspids, and the inside splint is retained.

May 4th.—The fissure in the hard palate has closed, and there is firm union of the superior maxillary bones. The lower jaw is still ununited, and the treatment is carried out as in the last note.

7th.—The left optic disc is extremely pale, the arteries considerably diminished. There are some white lines along the vessels. The right eye is apparently normal.

The temperature for the first week was higher than normal, reaching 100·8° to 102° in the evening, and being 99° or 100° in the morning; after this it was normal. The hæmorrhage from the left ear was slight, and the discharge which followed of small quantity. There was no vomiting. The strabismus was very marked at the time of discharge, forty-five days after admission.

CASE 2. *Dislocation of the left knee.* (From notes by Mr. TOTSUKA.)—T. K——, aged forty, a bargeman, was admitted June 21st, 1885, and remained under treatment fifty days. A few minutes before admission, whilst standing on a barge, a heavy rigging fell on his back; he was knocked down by the weight and twisted his leg in falling.

On examination there was found to be considerable deformity about the left knee-joint, the thigh was rotated outwards and abducted, and the leg rotated inwards and adducted, thus forming a distinct angle with the thigh. The tibia was found to be dislocated and strongly rotated inwards, the condyles of the femur being felt on the outer side. Owing to considerable rotation of the femur, the inner condyle was found situated directly in front of the outer, and the trochlear surface of the patella pointed directly outwards. The patella could be distinctly felt resting upon the internal condyle of the femur. The internal tuberosity of the tibia with its anterior surface could be felt projecting on the inner side of the joint. He was a strong muscular man. In addition to the pain in the knee he complained of pain in the left side, especially on drawing a deep breath or coughing, and on examination a contusion was found and crepitus elicited, there being two fractured ribs (? seventh and eighth).

The dislocation was reduced without difficulty by Mr. Sydney Jones, the patient being under the influence of chloroform. Plaster-of-Paris splints were put on the knee and a long outside splint applied to the limb. A flannel roller was applied to the chest. The temperature rose to 100·4° or 99·2° in the evening for a few days. There were no unfavourable symptoms.

ANCOATS HOSPITAL, MANCHESTER.

URETHRAL STRICTURE; PERINEAL ABSCESS; CONTINUOUS DILATATION; CURE; REMARKS.

(Under the care of Mr. E. STANMORE BISHOP).

A. S——, Arab, aged twenty-eight, was first seen on Oct. 18th, 1885. Had always had good health, with the exception of ague and several attacks of gonorrhœa, of which he

Digitized by Google

thought so slightly that he could not be certain of their number. Was sent to Syria this year whilst suffering from a gleety discharge, and whilst there had to spend several hours in the saddle; once or twice as many as twenty hours at a time. Has always lived freely, and smokes incessantly. Had noticed for some years that the stream of urine was narrower than it should be and somewhat forked. Has now intense pain on passing urine, which comes in a small stream, but with much force. The most intense pain, however, occurs about five seconds after urination, there being a quiet interval first, and lasts for some time, gradually becoming less. This pain he describes as burning and scalding in character. This acute condition has lasted five days, becoming steadily worse.

On examination at 10 P.M., a red, hot, swollen condition of the lower third of the scrotum, as well as the anterior portion of the perineum, was seen, the inflamed condition gradually blending with the normal tissue about half way between the anus and the scrotal line, or about the plane of the posterior edge of the triangular ligament, and in front the rest of the scrotum was in a normal state. There was slight epididymitis on the right side, from which a hardened cord passed towards the inflamed focus. The penis was tender, and there was a slight discharge of pus. Examination per rectum was not unbearable, but still painful, and showed a still full bladder, with a tender, somewhat enlarged prostate. Temperature 102·6°.

The diagnosis was perfectly plain—viz., a stricture of the urethra, probably at the spongio-membranous junction, behind which ulceration had taken place, with discharge of urine by it into the peri-urethral connective tissue, at first guttatim, but now most probably in moderate quantity, the main amount passing in when the *vis a tergo* was not sufficient to carry it in a quick stream through the stricture, but was flagging as the bladder became more empty.

With the assistance of Dr. Douglas, who first saw the case, chloroform was given, and an incision made in the median line through the tensest portion of the swelling, which allowed the issue of some unhealthy pus and a jet of urine. The cavity, which passed upwards by the side of the urethra, leaving its right side exposed in the wound, was washed out by perchloride solution, and a drainage-tube introduced. It was then dressed with perchloride lint and cotton-wool, and a T-bandage applied. The patient recovered from the chloroform well, and expressed himself free from pain.

Oct. 19th.—9 A.M.: The patient has had a good night. Temperature 99·8°. Urine passes both by the wound and by the urethra. The wound looks healthy; the swelling has already begun to subside; dressed with iodoform and sublimate lint. 9 P.M.: Temperature 100·3°.

20th.—8·30 A.M.: Temperature 101°. The patient has had a rigor; but there is evidence of his having had ague once or twice, and he is extremely nervous, almost hysterical. The wound looks healthy, and most of the urine passes by it in a fairly good stream. Dressed as before. Temperature, 9.30. P.M., 100°.

21st.—12.30 A.M.: Four grains of quinine were given in one dose. Temperature, 1.15 A.M., 103°; 2.15 A.M., 102·4°; quinine repeated.—3.30 A.M., temperature 102·2°; 4.30 A.M., 99·8°; 5.20 A.M., 99°; 6.20 A.M., 98·2°; 7.20 A.M., 98°; 10 A.M., 98·0°; 10.30 A.M.; wound dressed; some slough separating and plugging the opening; tube cleared and reintroduced. 12.30 P.M., quinine repeated.—2.20 P.M., temperature 100·2°; 2.30 P.M., quinine; 3.30 P.M., temperature 99 8°; 6.15 P.M., 99.4°; 6.30 P.M., quinine repeated; 10 P.M., temperature 98°; 11.30 P.M. 99·6°; quinine repeated.

22nd.—3 A.M., temperature 99°; 6 A.M., 99·4°; 9 A.M., 99·4°; 11 A.M., 99°; wound dressed.—3.30 P.M., temperature 98·4°; 6.20 P.M., 98·2°; 9.30 P.M., 97·6°; 12 P.M., 99·3°.

23rd.—6.30 A.M., temperature 99 2°; 9.30 A.M., 99·1°; wound dressed. 12.20 P.M., temperature 98 0°; 3 P.M., 98·0°; 6 P.M., 98·6°; 9.20 P.M., 99°; 12 P.M., 99·2°.

24th.—6.30 A.M., temperature 98·4°; 12 A.M., 98·4°; wound dressed.—6 P.M., temperature 98 6°; 10 P.M., 100°; quinine.

25th.—3 A.M., temperature 99·0°; 6 A.M., 98·6°; 12 A.M., 98·4°. Wound dressed; healing up well. Most of the urine now comes by the urethra. There is no swelling or tenderness about the scrotum, although a little thickening remains. There is a great amount of purulent discharge from the urethra, and there is some little straining required to start the stream of urine.—6 P.M., temperature 98·5°; 10 P.M., 98·5°.

26th.—9 A.M.: Temperature 98·4°; wound dressed.—9 P.M.: Temperature 98·4°.

27th.—10 A.M.: Temperature 98°. The temperature having now been normal for some three days, it was intended to attempt to pass a catheter or bougie on the next day, and as the patient was very fearful of pain, chloroform was given.—9.30 P.M.: Temperature 98·4°.

28th.—9 A.M.: Temperature 98·6°. Chloroform having been given, a large catheter was passed first, which was checked slightly half an inch inside and stopped at a point. An attempt was then made to pass an elastic catheter five inches from the orifice, but it was impossible. Gum-elastic was tried with no better success, and at last a No. 1 silver catheter (English scale) was carefully wormed through a very long and gristly stricture, which appeared to extend along the membranous urethra and some inches of the spongy portion. Before this could be done, however, the wound was broken open again by the finger of the left hand, inserted as a guide to the right direction. The catheter was left in.—3 P.M., temperature 99·3°; 6 P.M., 99·4°; 2 P.M., 99°.

29th.—8.30 A.M.: Temperature 99·4°. The urine has passed partly through the catheter, partly by the side of it, little or none by the wound; as he is pretty comfortable the catheter is allowed to remain. The wound is dressed as before with iodoform and perchloride lint.—6 P.M.: Temperature 99°.

30th.—10 A.M.: Temperature 99·4°. The catheter was removed and a No. 3 elastic was immediately substituted; this passed with ease and was tied in.—9 P.M.: Temperature 100°.

31st.—9 A.M.: Temperature 100°. Another dose of quinine. Catheter left in.—3 P.M., temperature 99·2°; 9 P.M., 99°.

Nov. 1st.—8.30 A.M.: Temperature 99°. No. 3 catheter removed and No. 5 placed in; this also passed fairly easily. The perineal wound has again nearly closed, and the drainage-tube was removed.—9 P.M.: Temperature 99·1°.

2nd.—8 A.M., temperature 99·4°; 8 P.M., 99·6°.

3rd.—9 A.M.: Temperature 99·6°. No. 5 catheter has slipped, and on attempting to replace it by No. 6 considerable difficulty was experienced; it was, however, left in position, but the patient complained of it as very painful.—3 P.M.: Temperature 101·2°. Quinine.—6 P.M., temperature 100°; 12 P.M., 100°. Quinine.

4th.—6 A.M.: Temperature 99·2°. Patient has pulled out the catheter, which appears to have become blocked, and as the urine passes pretty freely per urethram it is allowed to remain out for to-day. The perineal wound is closing, and there is no inflammation about the part.—6 P.M.: Temperature 99·4°.

5th.—9 A.M.: Temperature 99·2°. No. 6 catheter (elastic) again passed, and with comparative ease; left in as before.

6th.—9 A.M.: Temperature 102·0°. Quinine. Catheter left in.—3 P.M.: Temperature 98·3°.

7th.—9 A.M.: Temperature 99·5°. Catheter No. 6 removed, and No. 9 (elastic) passed, and left.—9 P.M., temperature 100·2°.; 12 P.M., 100 0°.

8th.—6 A.M.: Temperature 100°. Quinine.—8 A.M.: Temperature 99·5°. Catheter left in.—8 P.M.: Temperature 99·6°.

9th.—9 A.M.: Temperature 98·4°. Catheter removed and bougie No. 12 passed; left for five minutes and removed. Can now pass full stream of urine, with no straining and no pain. There was still a gleety discharge, but not constantly. Urethra to be distended with eucalyptus oil and olive oil (one part to four) twice daily; and the full-sized bougie to be passed every fourth day for a fortnight, after which time at gradually increasing intervals. The perineal wound is almost entirely closed, and no urine passes by it. The patient, who was very restless, appeared to have considered this condition satisfactory, as he has not attended again for the purpose of having the bougie passed.

Remarks.—This case is given in detail because, although not so complete as one could wish, it yet shows plainly that continuous dilatation is practicable immediately after the subsidence of inflammatory lesions consequent upon the stricture. The patient was an unfavourable one, of an extremely nervous temperament, and had suffered from malaria; but although the temperature went up from time to time during the treatment, it never reached a dangerous height, and appeared to be more due to the aguish tendency than to any direct traumatic cause, passage of catheters, &c.; inasmuch as whilst the catheter remained *in situ* quinine always brought down the temperature to a moderate level. The course of the perineal wound also was most satisfactory, although opened up a second time, in the very difficult introduction of the first instrument.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Leucocytosis.—Removal of Tumour from Brachial Plexus.

An ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. The discussion on both papers was well sustained.

A paper was communicated by Dr. Ringer on the Increase in Number of White Corpuscles in the Blood in Inflammation, especially in those cases accompanied by suppuration. The author of the paper was Mr. T. P. Gostling, of University College Hospital. The observations of Virchow, Nasse, and Malassez on the increase in number of white corpuscles in the blood in different inflammatory conditions were alluded to. The estimations recorded in this paper by the author have been made with a Gowers' hæmacytometer, and the results were given in percentage numbers of red and in relative numbers of white corpuscles, the normal number being taken as 1 white to 333 red corpuscles, as stated by Dr. Gowers. Estimations have been made in the following cases:—(1) Iliac abscess; (2) pelvic cellulitis and probably abscess; (3) suppurating white leg; (4) suppurating tonsillitis; (5, 6) white swelling treated by the actual cautery; (7, 8, 9, 10) empyemas; (11, 12, 13) phthisis; (14, 15) serous pleurisy; (16) lobar pneumonia; (17, 18) typhoid fever; (19) acute rheumatism. In the iliac abscess (Case 1) ten observations were made on separate days before the abscess was opened. The first half of these estimations showed the relative average number of white to red corpuscles to be 1 to 160; the second half, 1 to 101. The abscess was then opened, and the proportion immediately fell to 1 to 383, after which there was a slight increase, and then a steady decrease to the normal proportion, as is shown by the following averages: 1 to 203, 1 to 223, 1 to 252, and 1 to 358. In Case 2, which was one of pelvic cellulitis and probably abscess, there was found, for a long period, a large increase in the number of the white blood-corpuscles. As is shown by the averages given below, these covered a period of eighty-four days, and each average was made from five estimations: 1 to 148, 1 to 172, 1 to 150, 1 to 158, 1 to 167. During the above period grave symptoms existed, but on May 15th these commenced to improve, and at once the relative number of white corpuscles decreased to 1 to 250, and on May 19th reached the proportion of 1 to 366. It was thought that an abscess in this case had discharged by the bowel, and, if so, the sudden fall would correspond with that seen in Case 1. Analogous conditions were found in the other cases. The new series of observations were from cases of phthisis (Nos. 11 and 12), in both of which cavities existed in the lung-secreting pus. Cases of serous pleurisy, acute rheumatism, typhoid fever, pneumonia, and cauterisation were also considered with reference to the proportion of white corpuscles. The following conclusions were drawn: 1. That white corpuscles are increased in number in suppurative inflammations, especially when accompanied by tension. 2. That they are slightly increased in parenchymatous inflammations. 3. That they are not increased in inflammations accompanied by serous or sero-fibrinous exudation.—The PRESIDENT thought the observations were of much value.—Dr. SYDNEY RINGER said it was still a question whether the increase was due to multiplication in the blood or outside the vessels with subsequent absorption. It was a question also whether leucocytes did not multiply after emigration, or whether other cells than leucocytes could give rise to white corpuscles.—Dr. BERNARD O'CONNOR asked whether there was an actual diminution in the number of the red blood-corpuscles.—Dr. THIN believed that exuded corpuscles did multiply; the inflamed cornea of the rabbit was a site at which the various stages of fission of leucocytes could be seen. The stable cells did not multiply so far as his investigation went.—Mr. VICTOR HORSLEY said that our knowledge had been brought to this definite point by Mr. Gostling, that the increase of white corpuscles in the blood was connected with the local tension of an abscess; and the suggestion naturally arose whether there was reabsorption of white corpuscles. This point could be determined by estimating the number of corpuscles in a vein going from the inflamed area and comparing them with those in an artery going to the part.—Dr. ANGEL MONEY said that the research was one that had evidently occupied a large amount of time, and involved considerable labour, as would be allowed by those who had worked at the subject themselves. He had noted an increase in the number of white corpuscles chiefly in cases of phthisis and empyema. He thought that white corpuscles might be absorbed by the lymphatics, and so Mr. Horsley's suggestion would not be a conclusive proof.—Dr. SIDNEY COUPLAND said the observations were of much value, but still left us in doubt as to where all the white corpuscles came from, even in an ordinary inflamed area.—Dr. DOUGLAS POWELL inquired how long before the actual suppuration began the increase of the white corpuscles in the blood had been observed. He did not think that abscesses or empyemas were often absorbed.—Mr. VICTOR HORSLEY was of opinion that lymphatics did not act as absorbents from abscesses, but Dr. MONEY said he could not accept that position.—Mr. HOWARD MARSH said that large collections of pus unquestionably disappeared, and probably by absorption.—Mr. THOMAS BRYANT had seen very large abscesses become absorbed, and that very rapidly.—Dr. SIDNEY RINGER asked whether pus was absorbed as such, or only after having undergone fatty and other degeneration.—Mr. T. P. GOSTLING, in reply, said that a normal percentage of red blood-discs was not often observed in hæmacytometric calculations; generally there was a slight decrease. Cases 5 and 6 would show that there was a definite increase before actual suppuration occurred.

Dr. MITCHELL BRUCE and Mr. E. BELLAMY read a paper on a case of Removal of a Tumour from the Roots of the Last Cervical and First Dorsal Nerves. Their object in bringing this case before the Society was that it might possibly be of value in demonstrating the spinal origin of the ulnar nerve as far as regarded its relation with the brachial plexus. The patient, a lady aged fifty-four, and very stout, consulted Dr. Bruce about two years ago, with acute pain in the right arm, rapidly increasing; and with paralysis of the muscles supplied by the ulnar nerve and hyperæsthesia of the integument supplied by its cutaneous branches. The symptoms became so serious that entire loss of power of the arm ensued, with serious affection of her health. About eight months before the operation a tumour was noticed near the middle of the lower portion of the posterior triangle projecting just above the collar-bone, steadily increasing in size, firm, incompressible, almost immovable, and giving great pain on manipulation. In November, 1884, it was determined to cut down on the tumour in order to ascertain its nature. An incision was made such as would be adopted for ligature of the subclavian in its third part, but owing to the great depth and accumulation of fat, a vertical incision along the posterior border of the sterno-mastoid was added, and the growth readily reached. The great bloodvessels were carefully held out of the way, and the brachial plexus exposed, the cords of which were "frayed" out over the tumour. After some careful dissection, a growth, springing apparently from the under surface of the last cervical and first dorsal nerves, was uncovered just at their emergence from the intervertebral foramina, passing beneath the subclavian artery and jutting into the superior aperture of the thorax. No nerve trunk seemed to pass through it, and it was readily enucleated. A full account of the tumour was given in the paper. Almost immediately after its removal the patient lost the peculiar lancinating pain, but there was complete paralysis of the arm, owing to the free handling of the cords of the plexus during the operation. After the parts had thoroughly healed, the constant current was applied, increasing to fifty Leclanché cells, and by degrees perfect restoration of function ensued. In February, 1885, however, the patient was attacked with right hemiplegia, and died in the following October.—Mr. T. BRYANT related the case of a lady, aged fifty, in whom pains in the left arm and wasting of the extensor muscles and weakening of the flexors were the chief symptoms. There was a swelling above the clavicle, pressure on which increased the pain. A supernumerary rib or an exostosis was suggested. The tumour increased in size, and the forearm had become further wasted. An exploratory operation was made, and a tumour reached on the upper trunk of the posterior aspect of the brachial plexus, and was readily enucleated after the sheath of the nerve had been opened. The wound healed up in a few days. The pain did not at once entirely disappear, though it was less shooting and had altered in character. The pain ceased at the end of two months. Microscopical investigation led to the opinion that the tumour was a soft sarcoma into which hæmorrhage had occurred.—Dr. BERNON

said such cases were of much interest in neuro-muscular pathology and physiology, as throwing light on the distribution of the nerve-roots from which the muscles were supplied. The same subject had been treated by him in a paper published in the current volume of the Royal Medical and Chirurgical Society's Transactions. He also gave the results obtained on monkeys by Ferrier and Yeo. He was now investigating the subject by experimental researches on monkeys.—Dr. B. O'CONNOR related the case of a young lady in whom Mr. R. J. Godlee found on the anterior portion of the first rib an exostosis which had pressed upon the brachial plexus and produced painful and paralytic symptoms.—Mr. W. H. JESSOP asked whether there was any affection of the pupil. Stimulation of the second dorsal nerve in the monkey gave rise to mydriasis, and the first dorsal of the dog also possessed this function. The contraction of the pupil had been observed in a case of Mr. Pick's in which the brachial plexus had been injured.—Mr. VICTOR HORSLEY inquired as to the exact progress of the paralysis of the ulnar nerve; the case would be of no value for purposes of localisation after the tumour had been removed on account of the free disturbance of the whole plexus.—Dr. ANGEL MONEY said that Dr. Hughlings Jackson had narrated a case of progressive muscular atrophy of the small muscles of the hand in which the pupil on the same side was small and did not dilate when shaded.—Mr. STANLEY BOYD said that Mr. Jonathan Hutchinson had observed the contracted pupil in cases of rupture of the brachial plexus. The danger of wounding nerves in operations about the brachial plexus was alluded to, and the employment of flat retractors recommended.—Owing to the absence of Dr. Mitchell Bruce, the reply on medical questions was not forthcoming.

CLINICAL SOCIETY OF LONDON.

Desquamative Prostatitis with Hyaline Casts.—Cervical Spina Bifida.—Myositis Ossificans.

THE annual general meeting of this Society was held on the 8th inst., Mr. Thomas Bryant, F.R.C.S., President, in the chair.

Sir ANDREW CLARK related the case of Acute Prostatitis, with discharge of hyaline cylinders resembling renal cylinders, seen by Sir James Paget and himself. The chief interest lay in the circumstance that during the whole course of the case there were found in the urine hyaline cylinders and small flask-shaped hyaline masses, which in some instances were connected with the cylinders. The patient recovered by resolution. It is nearly seven years since the date of the attack, and the patient, a medical man, has remained quite well. Sir Andrew Clark alluded to two other cases, also of medical men, which had come under his personal observation. They might be mere curiosities of medical experience, but as no reference to the discharge of hyaline casts in prostatitis could be found in standard works or special monographs, he thought the case of sufficient importance to be brought to the notice of the Society.—Mr. T. BRYANT considered that the observation was one which merited careful attention. He asked in what way the casts could be distinguished from those of renal origin.—Professor GREENFIELD had met with four cases in which the urine contained concretions having somewhat the characters of corpora amylacea; the cases occurred in two girls and one young woman, and in one boy seven years of age. The concretions appeared intermittently. In one case he found the concretions in large numbers in the kidney after death; they stained deeply with carmine and magenta, and some with iodine. He mentioned these cases, not as of the same nature as Sir Andrew Clark's, but as worthy, like his, of further investigation.—Dr. J. G. GLOVER asked whether the patient had previously had a well-defined attack of gout.—Sir ANDREW CLARK replied in the negative to the last speaker. The characters of the casts were such as existed in the urine of cases of acute nephritis or acute congestion. A most important diagnostic point was the presence of flask-like bodies attached to the hyaline cylinders. The presence of prostatic trouble, and the fact that it was a healthy urine with the addition of a little albumen, were the other conditions that favoured the diagnosis of the prostatic origin of the hyaline casts. In two other medical men he had had illustrations of the same thing, but in neither of these was the disease so acute. The flask-like bodies were probably moulds of the follicles of the prostate. In the urine of women he always found a large quantity of mucus and veritable starch-granules, which were probably derived from the violet powder of the toilet.

Mr. CLUTTON read the notes of a case of Large Cervical Spina Bifida undergoing Spontaneous Cure. The subject was the younger brother of a patient in whom he had successfully treated a lumbar spina bifida by the glycero-iodine injection, and the particulars of which were reported to the Society in 1862. Both cases were shown as living specimens last November. The mother had had ten children, of which the ninth and tenth were affected as above mentioned. The latter was born in 1885 with a spina bifida in the cervical region of the spine, of which the size and position were demonstrated by means of a photograph. It was six and a half inches in diameter, and rather coneiform in shape, with the apex directed upwards. The coverings were thin, but completely enveloped with skin. It could be reduced in size by pressure, but increased again when the child cried. A considerable aperture could be felt in the vertebral arches. It was thought to be a simple running spina bifida, from the fact that there was a perfect cutaneous covering without any ulceration, median furrow, or central depression, that it was translucent in every part of its surface, and that there were no paralytic symptoms. When five weeks old the cyst was found to be much smaller, and its coverings quite soft and flaccid. No treatment of any kind had been adopted, and yet the communication with the interior of the vertebral canal had become occluded. From that time till December it diminished in size, when the child died from causes unconnected with the spina bifida. Mr. Shattock showed the specimen, which was obtained from the post-mortem examination. The posterior part of the cord was involved in the protrusion. The chief part of the latter was constituted by a closed sac of fibrous tissue, situated behind the protruded portion of the spinal cord.—Mr. R. W. PARKER thought that Mr. Shattock's anatomical description went to show that the case was not one of ordinary spina bifida; it could not therefore be used for the purposes of contrasting spontaneous cures with those effected by treatment. As far as the tables of the Spina Bifida Committee went, it would seem that more cures were brought about by treatment than by leaving the cases alone.—Mr. GOLDING BIRD asked what the child died of.—Mr. R. J. GODLEE referred to a case of spina bifida of the upper dorsal region in which there was a scarcely perceptible impulse. Treatment by the iodo-glycerine method led to paralysis of the lower limbs and retention of urine, which was treated by catheterism, on which cystitis developed and the child died some weeks later. Here was a case which seemed most favourable for treatment and yet led to disastrous results.—Mr. J. W. HULKE said that the diagnosis was sometimes exceedingly difficult. He remembered a case in which a slender tubular prolongation connected the sac with the spinal canal; removal was followed by suppuration and death in forty-eight hours.—Mr. J. H. MORGAN said it would be very interesting to know in what the shrinking changes consisted. He well remembered a case of spina bifida of the upper dorsal region under Mr. T. Holmes's care in which there seemed to be almost no connexion between the tumour and spinal canal, yet removal led to immediate syncope and rapid death.—Mr. CLUTTON, in reply, said the child died of some diphtheritic affection. The question was whether it was a pure meningocele or meningo-myelocele, but it was a spina bifida all the same. Spontaneous shrinking was far more favourable than shrinking by treatment. The shrinking was very marked, and the opening between the tumour and the spinal canal or cord must have almost closed, for the impulse on coughing and other signs of like significance altogether disappeared as the shrinkage went on.

Mr. SYMPSON (Lincoln) read notes of a case of Myositis Ossificans, which occurred in a boy aged seven years. He first saw the case on March 27th, 1885, when there was much complaint of pain and tenderness about the right shoulder; a tumour was noticed along the posterior boundary of the right axilla, and another on the left axilla; these growths were larger, more elastic, and nodulated than they were now. There was no history of syphilis. Fresh tumours appeared a month later on the right ilium, and later still over the left eleventh rib.—Mr. J. HUTCHINSON gave a brief report of the conclusions that the Special Committee had arrived at. The case was regarded as a most

Digitized by Google

remarkable case of myositis ossificans, affecting chiefly the latissimus dorsi and trapezius on both sides, also the triceps on the right side. There was no certain proof of any exostosis independent of the muscles. A remarkable feature was the existence of a "saddle" of bone extending completely round the loins, and preventing movement of the trunk. There was no ossification of muscles on the anterior surface of the trunk. The shoulder-joints were fixed by the result of the ossification in muscles. Another feature that was drawn attention to was the occurrence of ossification in the form of bony lumps or nodules, not in plates and spinous processes, as was the rule in myositis ossificans.

The following living specimens were shown:—Dr. Pringle: Symmetrical Guttate Scleroderma. Mr. Sympson (Lincoln): A case of Myositis Ossificans. A special committee, formed of Mr. J. Hutchinson, Mr. H. H. Clutton, and Dr. W. H. Allchin, was appointed to investigate the latter case. (*Lancet.*)

MEDICAL SOCIETY OF LONDON.

Treatment of Varicocele.—Lardaceous Hepatic Disease.—Athetosis.

A SPECIAL meeting of this Society was held on Monday last, Dr. W. M. Ord, President, in the chair.

Mr. BARROW read a paper on a new method of treating Varicocele by Excision. It was most important to protect the spermatic cord from injury. This was accomplished by separating the diseased veins from the cord, and then silkworm needles were passed behind the veins and served as a platform to them, and facilitated the operation. An incision was made from the external abdominal ring to the scrotum so as to allow of retraction of the skin and fully expose the veins. The pins were then removed, and the wound closed and dressed. In ten days or a fortnight the patient left the hospital, the wound healed by first intention, and there was no constitutional disturbance. He considered that this operation would compare favourably with others; it was certainly most radical.—Mr. A. P. GOULD had employed division of spermatic veins by means of the ecraseur thirty times, and excision of the veins about fifty times, and he preferred the former operation. He had given up excision, for he had witnessed evil consequences from the practice of other surgeons. He considered the incision was unnecessarily long. It was, in his experience, difficult to get the scrotal skin to heal by first intention.—Mr. BERNARD PITTS said in one case of excision of the veins he had experienced considerable trouble from suppuration spreading widely necessitating incision, and greatly prolonging the convalescence. He had also seen much wasting of the testicle, probably as the result of free excision of parts. He thought the operation was necessarily severe for most cases of varicocele.—Mr. LORD EDWARDS had seen symptoms probably due to pulmonary embolism, after a case of excision of the varicose veins. He preferred Ricord's operation.—Mr. J. HUTCHINSON thought it was somewhat surprising that atrophy of the testis was not more frequent, as the spermatic veins not uncommonly ran in the so-called anterior bundle of the cord veins.—Mr. BARROW, in reply, thought the size of the wound was of no consequence if the antiseptics were used. He used salicylic wool as a dressing.

Mr. BERNARD OWEN showed a case of great improvement in Albuminoid Disease of the Liver. The patient was a boy aged twenty-five, who had suffered from gastric symptoms for some months; slight jaundice had been noted for six months, and a tumour in the epigastrium for three months. Frequent micturition was another symptom. The patient was first seen in Nov. 1884. The liver was found to be greatly enlarged, and the tumour was a projection from it. The spleen could be touched below the ribs. The urine was of low gravity of 1018, and contained bile and about one-fifth albumen. Lardaceous disease was the diagnosis. There was no history of suppuration or syphilis. An ordinary iodide of potassium treatment was prescribed; mercury was also given. The liver gradually diminished in size, and the organ was probably now not more than one-third its original size. The gastric and other symptoms had disappeared.—Dr. PRINGLE had under his care [illegible] there was evidence of syphilis many years before. The projection was probably a gumma. He had ordered 20-grain doses of iodide of potassium three times a day, with excellent results.—Dr. ORD said that the presence of an isolated tumour and of tenderness was an unusual circumstance in the case, supposing it to be one of pure amyloid disease. He considered that the disease was probably syphilitic as well as albuminoid. He inquired whether the blood had been examined.—Dr. PURCELL had seen a similar condition of the liver in a nurse who was evidently syphilitic.—Dr. KINGSTON FOWLER considered that external evidence of syphilis was frequently wanting in cases where the syphilitic disease was internal. Regarding the case as one of syphilitic cirrhosis, he said it was rare for the liver to be affected with lardaceous disease before the spleen.—Mr. WALTER PYE suggested a mechanical origin for the albuminuria.—The PRESIDENT elicited that the amount of urine secreted was increased and so negatived this suggestion.—In reply, Dr. ISAMBARD OWEN said that the projection was hardly of the nature of an isolated tumour, but merely the bulging of a generally enlarged liver.

Dr. BEEVOR showed a case of Left Athetosis in a girl aged twenty, which had come on after fits following an attack of whooping-cough when the patient was two years old. The hand was chiefly affected. There was no anæsthesia. She had left-sided fits, beginning with an epigastric aura and twitching of the left hand, and followed subsequently by temporary left-sided paralysis. The lesion was considered to be softening of the cortical centres of the left arm and leg following thrombosis after whooping-cough. Attention was drawn to the presence of athetosis and epileptic fits on the same side, and to the prevalence of the epigastric aura with left-sided fits, which was considered to be a symptom, and not a cause, of the attacks.—Dr. STRETCH DOWSE was glad that Dr. Beevor took exception to the view that the internal capsule was the seat of the lesion in all cases. In his opinion, the cortex might be the seat of lesion. In many cases there was great loss of intellect.—In reply, Dr. BEEVOR said that the number of fits might account for whatever of mental deficiency might exist.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Housing of the Working Classes as it affects the Status of Medical Officers of Health.

A MEETING of this Society was held on Dec. 18th, 1885, at 1, Adam-street, Adelphi, the President, Dr. W. H. Corfield, in the chair.

A paper was read by Dr. E. C. SEATON entitled "The Recommendations of the Royal Commission on the Housing of the Working Classes as affecting the Status of the Medical Officer of Health." The recommendations to which the author of this paper alluded are: (1) that medical officers of health should in future appointments be required by sanitary authorities to give their whole time to their official duties; (2) that they should be required to live within a mile of the district which they serve. The object of the paper was to show that in the present state of public opinion, and with areas of local government as at present constituted, such restrictions as those recommended are calculated to retard rather than to advance the progress of that cause which all health officers have at heart—the extension and application of medical and scientific knowledge for the benefit of the public health. The question of the status of the medical officer of health—that is to say, the character of his duties, his relation to his fellow-officers, and his emoluments and tenure of office—is the most important one that has to be considered in relation to the public health. The author has always had doubts of the wisdom of that policy which has led some earnest sanitarians so strenuously to advocate as a general principle that which, for the sake of brevity, might be described as "whole service," except in occasional instances, such as the very large combined areas and perhaps towns of the first magnitude. After quoting the opinion of Dr. Gairdner, Mr. Simon, and Dr. Buchanan in favour of the view that advantage was derived by the medical officer having opportunities for hospital practice, an account was given of a supposed dialogue between two medical officers—the one who argued in favour of the "whole," the other of the "partial service" system. In this dialogue it was argued that

Digitized by Google

medical officers of health should not assume too much responsibiliy in connexion with legal matters, and that they should avoid appearing in courts of law as advocates or prosecutors, but rather adhere to their proper position as scientific witnesses. It was further pointed out that on such questions as those connected with unhealthy houses, sewage-disposal, water-supply, &c., there was much risk of their coming into collision with engineers, surveyors, architects, and professional chemists (who upon some aspects of these questions were, generally speaking, more entitled to be considered experts), unless they adhered strictly to their own special province as medical officers. Particular attention was also directed to the important duty of a medical officer of health as an adviser of the sanitary authority on all municipal questions affecting the public health, such as hospital accommodation, sanitary administration and police, excrement removal and disposal, water-supply, &c.; and to another equally important duty which devolved on him, of scientifically studying the causes of the origin and spread of outbreaks and epidemics of disease. Dr. Seaton was of opinion that, assuming that the professional arguments on both sides were equally balanced, as a general policy, apart from other considerations, the whole-service system is opposed to the highest public interests, because the public would in the future be deprived of the services of medical experts, such as those who in various ways have so largely contributed to scientific knowledge in the prevention of disease, but who could not be expected to sacrifice everything for a profession in which the usual incomes are very small and precarious, and which, as a profession, may be said to be without prizes; also, because among the towns and districts which have required the whole services of medical experts there are many which are evidently not sufficiently large to need them, as is clearly shown by the fact that the officers appointed for this purpose have undertaken, or had imposed upon them, duties which do not require any professional knowledge, and which might be performed quite as well, and at less cost to the public, by non-professional persons; finally, because the insecurity of tenure makes it very difficult for a medical officer of health, who is cut off from all other means of earning a livelihood, to discharge his duties with sufficient independence, and this want of proper independence would be especially felt in cases where the authority was largely composed of small property owners, who were opposed to sanitary work. In conclusion, he alluded briefly to the proposed restriction with regard to place of residence, and pointed out that such a restriction would interfere with the combination of sanitary districts for the purpose of appointing a medical officer of health, an arrangement which generally worked so well; and further, that in London the facilities for locomotion were such that from central positions medical officers could reach any part of their parishes or districts in the shortest time.—In the discussion which followed, the President, Mr. Armstrong, Dr. C. E. Saunders, Dr. Swete, Mr. W. Blyth, Mr. Lovett, Mr. Jacob, and Dr. Bate took part.

ACADEMY OF MEDICINE IN IRELAND.

Madura Foot.—Milky Fluid in the Peritoneal Cavity.—Rupture of Intercranial Vessel.—Osteomalacia.

AT a meeting of the Pathological Section held on Dec. 4th, 1885,

Dr. E. H. BENNETT exhibited a specimen of Madura Foot which had been presented to the museum of the University by Surgeon Burke, of the Indian Medical Service, a former pupil in the School of Physic and a graduate of the University. The specimen was obtained by amputation for the relief of the disease, which occurred in a coloured woman, an inhabitant of Central India.

Dr. DUFFEY exhibited a specimen of a Milky Fluid removed by Paracentesis during life from the peritoneal cavity of a single woman, aged fifty-two; and also portions of the viscera from her body. He briefly referred to the different forms in which a fluid resembling milk is met with pathologically, and said that he believed many of the so-called cases of "chylous" ascites were so only in name. In Dr. Duffey's patient the fluid was certainly not chylous. The case was one of chronic diarrhœa of five months' duration, during the last six weeks of which there was, in addition, ascites. The abdomen was tapped three times. On each occasion a milky fluid was withdrawn. Erysipelas supervened after the last tapping, and the woman, who had become very weak and emaciated, died. On post-mortem examination the parietal peritoneum was found to be thickened and opaque, and, as well as the costal pleura, sprinkled over with small white fibrous nodules, which were likewise plentifully bestrewed over the greatly thickened omentum and the serous envelope of the intestine. In Douglas's pouch there was a considerable deposit of nodules, which in some places had coalesced and looked like caseous masses commencing to soften. There were enlarged glands in the lesser omentum and in the vicinity of the cæcum. Numerous small ulcers were found in the cæcum itself and adjoining portion of the large intestine; and both segments of the valve were much thickened and ulcerated. The thoracic duct and its branches appeared quite normal. Dr. Duffey believed the case to be one of tuberculosis, but he could not say what was the cause of the colour of fluid, or what connexion, if any, there was between it and the chronic peritonitis. So far as these two circumstances went, the case seemed to support the conclusion recently advanced by M. Letulle (*Rev. de Méd.*, Sept., 1884), to the effect that a chronic inflammatory element is the most constant character in the genesis of such chyliform effusions.—Dr. FOOT said he had a case of this kind in which he tapped the patient four times for effusion into the peritoneal cavity. Mr. Scott analysed the fluid, and found in it 25 per cent. of sugar and a notable quantity of urea, which he expected, as the man was suffering from parenchymatous nephritis and general dropsy. But his limbs and scrotum had to be punctured, which was done without any bad results; and the fluid which issued from these punctures, of which he made about 150, was as limpid as dew. On the other hand, the fluid that came from the peritoneal cavity was like milk-and-water; and similar fluid came up from the man's stomach. By the four tappings twenty-four quarts of this milky fluid were taken from him. Its specific gravity was from 1004 to 1006.—Mr. STORY asked if Dr. Duffey had found any microscopic evidence of the presence of bacilli.—The PRESIDENT remarked that after two or three tappings, the man whose case was the subject of Dr. Duffey's communication had an attack of erysipelas, which assumed a gangrenous character, and perhaps was the cause of his death. The supervention of erysipelas was very rare after tapping for ascites. Where did it start from in the case in question?—Dr. DUFFEY, in reply, said he believed most analyses that had been made of the kind of milky fluid in question had shown the presence of sugar. In his case the fluid had not been examined for sugar. Dr. Foot's case bore out the view that a great many cases of the kind were due to chronic peritonitis. A microscopic examination of a portion of the fluid drawn off at the second tapping showed some endothelial cells and exudation corpuscles. There was no microscopic evidence of bacilli; Dr. Purser and other gentlemen had detected none. But there was a case of convalescent erysipelas in the ward, and in consequence every precaution as to cleanliness of instruments and disinfection was taken. The erysipelas started from the site of the third puncture made in the patient, gradually extended, and in a short time assumed a bluish appearance. There was no vesication, and the erysipelas did not extend into the peritoneal cavity.

Dr. J. K. BARTON made a communication on a Tumour of the Internal Saphena Vein. It was about the size of a pullet's egg, and was evidently formed by an expansion of the coats of the vessel. It was filled with a clot so firm and adherent to the lining membrane that it could with difficulty be separated.

Dr. FOOT exhibited the Heart and Kidneys from a case of Bright's Disease. The kidneys were typical examples of the contracted granular kidney as described by Richard Bright. The heart was hypertrophied, weighing thirty-two ounces, the hypertrophy chiefly affecting the left ventricle. Neither valvular disease nor atheroma of the aorta was present, but the surface of the heart was covered with a regular sheet of pericardial exudation. The chief clinical feature in the case was the presence of persistent hæmatemesis.

Dr. MACSWINEY exhibited the Brain of a Man who had died from Rupture of an Intercranial Vessel. The man, aged sixty, was brought to the hospital that day week in an insensible condition. He was quite unconscious, immovable, and without sign of sensibility. He was a labourer, and was actually at work that day. A few hours

Digitized by Google

before the fatal attack he complained of pain in his head. That did not deter him from continuing his work, and he was in the act of levelling a wall with a crowbar when he fell. When persons came to his assistance he was conscious and could speak, but was unable to walk; but consciousness and power of speech rapidly left him, and in two hours after the attack, when he was brought to the hospital, he was in the state which he (Dr. MacSwiney) had described. His face was pale and his eyes contracted and immovable, but he had no stertorous breathing. His pulse was feeble and rapid. The sphincter of his bladder was paralysed, and he passed a quantity of urine, which trickled to the floor. His left upper and lower extremities were extremely rigid and almost tetanically contracted. He lived about fourteen hours after his first seizure. After death the brain was removed. The convolutions on the left side were very much flattened, and there was considerable subarachnoid effusion of blood on the surface of the convolutions. The base of the brain was occupied by a very large effusion of blood. It appeared that the blood burst through the arachnoid, and was effused into the arachnoid space. When the blood had been removed, it was found that on the left side there was an aneurysmal dilatation of one of the branches of the internal cerebral artery which had given way. There was a very large hæmorrhagic focus, which had torn through the white substance of the frontal convolutions and excavated a large cavity, which was filled with clotted blood, and the sides of which were formed of projections of lacerated brain substance. The ventricles had not been opened, but he had no doubt that there was blood in them. Arterial hæmorrhage in the brain generally resulted from the rupture of a diseased vessel, and in the present instance the diseased vessel showed the form of degeneration known as atheroma, which was not the most usual form that existed in the arterial dilatations described by Charcot. He had no doubt that the efforts the man was making were the cause of rupture.

DR. E. H. BENNETT exhibited specimens taken from a patient suffering from Osteomalacia, who had been under his observation for several years before her death, and during the entire period of her disease. The case was exceptional in this, that while the woman was comparatively young, being at her death about thirty-nine years of age, pregnancy had not occurred as the starting-point of the disease, nor were the conditions of life such as could be assigned as the cause. She had lived in the capacity of upper nurse in most comfortable situations and in various climates, in England, Ireland, and in France. The chain of events in the progress of the disease was spontaneous fracture of the left clavicle, after union of this its refracture, a fracture of the shaft of the humerus at its upper extremity, followed at intervals of several months by successive fractures of the same bone in its upper half, each fracture uniting well and in the usual time for healthy bones. During the treatment of the last of these accidents, just as the repair was completed, the shaft of the femur on the same side broke in its upper half as the patient turned in bed. At this time she suffered severe pains in the lower limbs and back, and particularly in the right thigh—such that one began to expect the occurrence of fracture of that bone also. She could not bear the restraint of a Liston splint, and milder means were adopted; but the patient suddenly died from failure of the heart. Her fingers had become remarkably clubbed at the ends, while the nails were corrugated—points which raised a suspicion of pulmonary phthisis, but of this there were no signs during life and no evidence post mortem. The bones, which had been the seat of pain as well as those that were broken, presented a dull mottled appearance, and were so softened that a scalpel could easily be thrust through their tissue, even through the shaft of the unbroken femur. The medulla was brownish, fatty and free from red colourisation. The kidneys were studded everywhere with fine grains of dull white particles of gritty sand, against which the edge of the knife grated in cutting the cortical and medullary tissues, but there was no free sand or calculus in the hilum, ureters, or bladder. Chemically examined, these grains were found to be composed of mixed phosphate and carbonate of lime—to be, in fact, bone-earth. Structurally they were amorphous. The liver and spleen were free from disease. The heart was very small, thin, and soft, and evidently fatty. Dr. Bennett discussed the relation of this affection to rickets and to senile osteoporosis, pointing out the characters which appeared to him to distinguish them.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Difficulties of Diagnosis in certain Cases of Cerebral Tumour.

AT the meeting of this Society held on Jan. 1st,

Dr. HALE WHITE read a paper on the Difficulties of Diagnosis in certain Cases of Cerebral Tumour. The author first related particulars of a case in which no cerebral symptoms whatever were known to be present during life, but at the necropsy the presence of a tubercular mass in the cerebellum was quite accidentally discovered. Then full particulars were given of an interesting case of tumour in the frontal lobe. In this patient for a long time, the only symptom was headache, and it was not till a short period before death that the presence of optic neuritis was discovered. The patient died suddenly without the advent of any other than these two symptoms. The next case related was one of a woman, in whom a tumour in the region of the occipital and temporo-sphenoidal lobes existed; it was about the size of a Tangerine orange, and produced no symptoms whatever that could with certainty be referred to its presence. It was concluded from these three cases that tumours might exist in the cerebellum, frontal lobes, and occipital region, and be very difficult of diagnosis. The presence of paralysis of some of the cranial nerves did not necessarily forbid the diagnosis of the presence of a tumour in this region, for if it were of a very great size its pressure might compress the nerves at the base of the skull against the bone. Tumours in the regions just indicated have no special symptoms, such as paralysis; therefore, for their diagnosis we are entirely dependent upon the general symptoms—viz., headache and optic neuritis; vomiting occupying an intermediate position, being partly a general and partly a special symptom of tumours near or in the cerebellum. Even the combination of headache and optic neuritis did not conclusively prove the existence of a cerebral tumour, for a case was brought forward in which both of these symptoms were present, both being due to anæmia, the patient rapidly recovering on treatment with iron; still, the combination of these two symptoms would make one extremely suspicious. The form of headache most likely to be associated with cerebral tumour was next discussed, and it was pointed out how frequently, if not careful, a mistake might be made with myopic patients, who often complained of dimness of sight and headache. The next question raised was as to the means of diagnosing the kind of tumour, but it was pointed out that this was not of so much importance as to diagnose its presence, because one's duty to a patient is always to give large doses of iodide of potassium.—Dr. PURVES moved a vote of thanks to the author, and gave an interesting account of a case in which the diagnosis lay between embolism and hysteria.—Dr. CABLE, in seconding the vote of thanks, related several cases of cerebral tumours.—Dr. ERNEST CLARKE made some suggestive observations with regard to optic neuritis in cerebral tumours.

Reviews and Notices of Books.

English Worthies. Edited by ANDREW LANG, CHARLES DARWIN, and GRANT ALLEN. pp. 206. London: Longmans. 1885.

This is the first of a series which is to include Marlborough, by George Saintsbury; Steele, by Austin Dobson; Sir T. More, by Cotter Morison; and many others. The present volume is an appreciative account of the life and works of the great naturalist, who has been styled the "Newton of Biology" and the "Joshua who led the world of thinkers and workers into full fruition of that promised land, which earlier investigators had but dimly descried from the Pisgah-top of conjectural speculation." Mr. Grant Allen shows, in a good introductory chapter, how the germs of Darwin's great doctrines of the mutability of species and their origin from a common form were sown by Buffon, nurtured by Geoffrey St. Hilaire and Goethe, and largely developed by Erasmus Darwin, by Lamarck, and later by Lyell, till it was fully matured by Charles Darwin,

Digitized by Google

and appeared in the form of modern evolutionism, which rapidly overthrew the previously dominant views of violent revolutions, cataclysmal changes, and new creations. That Darwin was descended from the Wedgwoods through his mother is well known. The grandson of Erasmus Darwin and of Josiah Wedgwood, it is not surprising that Charles Darwin was an accurate observer and an acute and original thinker. The importance of Darwin's early travels in the voyage of the *Beagle* cannot be over-estimated in their influence on his mind, and in many passages he expresses himself in a manner that show the dawning of his later views. Referring to the calm consideration which Darwin devoted to the materials he brought home from all parts of the world in the *Beagle*, Mr. Grant Allen observes that they give us "in a nutshell the true secret of Darwin's success in compelling the attention and assent of his contemporaries to his completed theory." In the "Origin of Species" he brought together an imposing array of closely serried facts, secured every post in the rear before taking a single step onward, and brought to bear upon every antagonist the exact form of argument with which he was already thoroughly familiar, and most of the facts were drawn from his observations whilst acting as naturalist to the *Beagle*.

Great as was the impetus given by Darwin's researches to the study of animal life, that to botanical work was almost equally strong, and Mr. Allen reminds us that, in regard to the single question of the "Fertilisation of Flowers," Mr. D'Arcy Thompson has collected a list of no less than 814 separate works or important papers bearing on that special department of botany—almost all of them subsequent in date to the first publication of the "Origin of Species"; and the number of workers now engaged in the solution of the problems opened up by that work in this country and abroad is incalculable. Taking Mr. Allen's book as a whole, it may be regarded as a history of Darwinism, rather than as an account or biography of Darwin—a description of the origin and progress of his doctrine, than a history of the individual. It, however, commences a series of volumes that, if followed by others of equal value, promise much entertainment, and are thoroughly deserving, not of perusal only, but of study.

Diseases of the Tongue. By HENRY T. BUTLIN, F.R.C.S., Assistant-Surgeon and Demonstrator of Practical Surgery, St. Bartholomew's Hospital. Pp. 451. Cassell & Co.

As Mr. Butlin remarks in his introductory chapter, there are certain difficulties in carrying out the encyclopædic plan—which he has adopted,—inasmuch as "some of the diseases are of such a kind that each one of them comprises in itself several, or many, different physical conditions of the surface of the organ." In other words, this particular method necessitates a good deal of repetition, and involves much cross-division. Had the procedure usually practised been selected, of describing in narrative form the diseases of which a book treats, rather than making abnormal signs often common to many pathological conditions the cardinal point of dissertation, a good deal of space would have been saved, and the book before us would probably not have exceeded two-thirds its present size. The treatise, however, is written for "practitioners and students of medicine," and the former will be glad of an arrangement which affords them a convenient and ready reference to the phenomena of disease. We do not wish to be captious or hypercritical, but it occurs to us, on careful perusal of Mr. Butlin's work, that a few diseases of rare occurrence are given too much prominence—e.g., "Tongue-swallowing," which some may scarcely have heard of, and most have never seen, takes up five pages. The treatment recommended of the several morbid states of the tongue is thoroughly sound; but here, again, we meet with a good deal of repetition which might to some extent have been avoided. Apart from the objections above raised, we have nothing but praise for Mr. Butlin's Manual. Many chapters are models of concise writing and logical reasoning, and this is especially the case with those devoted to "Carcinoma" and "Syphilis." As regards the latter two we could wish nothing better. The section devoted to "Macroglossia" is another instance of lucid exposition, and shows marked clinical acumen. The book, which is copiously and beautifully illustrated with chromo-lithographs and engravings, will add greatly to the reputation of its author, and be highly prized not less by the busy practitioner than the student.

OUR LIBRARY TABLE.

Lectures on Diseases and Injuries of the Ear. Delivered at St. George's Hospital. By W. B. DALBY, F.R.C.S., M.B. Cantab, Aural Surgeon to the Hospital. Third Edition. London: J. and A. Churchill. 1885.—That another edition of this now well-known book has been called for is of itself evidence that it is popular with the profession. The opportunity of revision has given Mr. Dalby the opportunity of dealing in this edition with the adenoid growths in the pharynx to which Dr. Meyer first called special attention, and which have been shown to be of great importance in connexion with inflammatory changes in the middle ear. The chapter dealing with this matter adds nothing to the common knowledge of the malady, but it supplies an important omission in the previous edition. The subjects of affections of the brain following diseases of the ear and the mode of estimating degrees and varieties of auditory acuteness are more fully dealt with than before. The conversational style originally adopted has been preserved, and indeed it would be impossible to alter this without rewriting the entire book. This style has considerable advantages, chiefly in making the book very readable. It has also, of course, its disadvantages in its lack of precise order and fulness of detail, so that as a book of reference it is less useful than a systematic treatise, especially as the index is very scanty. But of systematic treatises we have enough, and we are glad when we get a readable account of the experience of one who has had large opportunities of observing the diseases and injuries upon which he writes. If Sir W. B. Dalby will add a complete analytical index to the next edition of his work, he will greatly enhance its value to the practitioner.

A Schoolmaster's Retrospect of Eighteen and a Half Years in an Irish School. By MAURICE C. HIME, M.A., LL.D., Head Master of Foyle College, Londonderry.—We have read with interest "A Schoolmaster's Retrospect." All that pertains to education is of the first importance to medical men. The best minds in the profession are engaged in imparting knowledge to others. Any hints given by a practical schoolmaster of large experience cannot fail to interest. Dr. Hime's book is evidently the outcome of a great deal of thought, and of very considerable experience during eighteen and a half years. He discusses a great many topics, some of which we will briefly notice. He is opposed to the idea that the art and science of education are of easy attainment, and offers some very sensible observations on this matter. Corporal punishment and all forms of punishment are condemned. "Corporal punishment appeals only to boys' fear as a motive; and what a wretched motive is fear! How improving and elevating, on the other hand, to appeal to and evoke and strengthen his reasoning powers and his love. Fear can have no terror for a boy except when present with him, and this it clearly cannot always be. Love of right and love of parents, though, can be always present with him. Develop this love in him, and alike before your face and behind your back he will try to do his duty." Cramming finds no advocate in this little

Digitized by Google

book, but thorough knowledge and a great deal of self-education are insisted on. Dr. Hime finds fault in some particulars with existing methods of education. He upholds the great value of the ancient classics as a foundation in education, and thinks the teaching of science ought to be deferred. In this view he is at variance with a great many modern writers. The education of the senses commences spontaneously at a very early period of life, and this important part of education receives very little development in the present state of school training. The practical teaching of science, it may be said, would require laboratories, which are not to be found in our schools. To this it may be answered that much information in science could be imparted from the study of many common objects which thrust themselves on our attention in every-day life. Dr. Hime holds that every schoolmaster ought to be a medical man. He says: "A schoolmaster ought to understand thoroughly all questions relating to the bodily and mental health of his pupils." Most men who take the trouble of getting the M.B. degree, suggested by Dr. Hime, will probably prefer continuing the all-absorbing study of medicine to undertaking the office of schoolmaster, of the practical duties of which they know little or nothing. It would require years of successful practical work before a man could attain to the enthusiasm for a schoolmaster's work which is possessed by Dr. Hime, as evidenced in the pages of this work. It cannot be insisted upon too strongly that a knowledge of physiology is of the utmost importance, not only to the schoolmaster, but also to every individual. Herbert Spencer, in his work on Education, says: "We infer that as vigorous health and its accompanying high spirits are larger elements of happiness than any other things whatever, the teaching how to maintain them is a teaching that yields in moment to no other whatever. And therefore we assert that such a course of physiology as is needful for the comprehension of its general truths, and their bearings on daily conduct, is an all-essential part of a rational education."

An Index of Surgery; being a concise Classification of the main Facts and Theories of Surgery, for the use of Senior Students and others. By C. B. KEETLEY, F.R.C.S., Senior Surgeon to the West London Hospital, Surgeon to the Surgical Aid Society. Third Edition. London: Smith, Elder, and Co. 1885.—The alterations and additions made in this edition of Mr. Keetley's now well-known book are few and insignificant. In the article on the Surgery of the Ovaries and Uterus Mr. Alban Doran has added notes on Porro's operation and on diseases of the Fallopian tubes. Mr. Juler has also made his article on Ophthalmic Surgery more complete. If used properly—that is, as an accessory to systematic treatises, and not as a substitute for them—the book may be of great benefit to students. The value of the book depends entirely upon the way in which it is used.

Quarterly Journal of Microscopical Science. Edited by Professors LANKESTER, DYER, KLEIN, MOSELEY, and SEDGWICK. No. CI., Nov. 1885.—This part contains five memoirs:—1. J. T. Cunningham: On the Relations of the Yelk to the Gastrula in the Teleosteans; with four plates. In this paper the author gives descriptions, measurements, and illustrations which set forth the peculiarities characterising the eggs of the several species, and also furnishes some explanation of the steps by which the process of development has been produced by the contending influences of heredity and adaptation. 2. Howard Ayers: On the Structure and Function of the Sphæridia of the Echinoidea; with one plate. The author supplies evidence showing that they possess the double function of taste and smell. 3. A. B. MacCallum: The Nerve Terminations in the Cutaneous Epithelium of the Tadpole. Some of the fibrils, he shows, enter the epithelium and terminate in comparatively large bead-like bodies between the cells; others terminate in excessively fine fibrils, of which one, two, three, or even more, terminate in the interior of each epithelial cell near its nucleus. 4. Ray Lankester: On Green Oysters; with one plate. The colour appears to be deposited in certain cells of the gills of the oyster, and to proceed from the Navicula ostrearia, which is ingested by the oyster as food. 5. John Beard: The System of Branchial Sense-organs, and their associated Ganglia in Ichthyopsida; with three plates. This is a contribution to the ancestral history of Vertebrates.

The Journal of Physiology. Edited by MICHAEL FOSTER, F.R.S. Vol. VI. No. 6.—This part contains the following articles:—I. D. W. Samways: A Double Differential Rheotome; with one plate. 2. W. D. Halliburton: On the Blood of Decapod Crustacea; with one plate. 3. S. Martin: The Nature of Papain and its Action on Vegetable Proteids. 4. S. Ringer: Regarding the Influence of the Organic Constituents of the Blood on the Contractility of the Ventricle; with one plate. 5. J. G. Adami: On the Nature of Glomerular Activity in the Kidney—a valuable contribution to the comprehension of the process of secretion. 6. F. M. Ellis: Plethysmographic and Vaso-motor Experiments with Frogs; with two plates. 7. W. H. Waters: Some Vaso-motor Functions of the Spinal Nerves in the Frog.

The Journal of Mental Science.—The current number contains the following articles: On the Alleged Fragility of the Bones of General Paralytics, by Dr. T. Christian; Some Points in Irish Lunacy Law, by Mr. Conolly Norman; Design for a Public Asylum for 310 Patients, by Dr. S. Cobbold; On a Recent Visit to Gheel, by Dr. Hack Tuke; An Unusually Heavy Brain in a General Paralytic, by Dr. McDowall; Two Cases of Melancholia, by Alex. Patton, M.B.; Cases in which Hæmaturia and Appearances as of Several Bruises occurred Spontaneously in the Course of an Attack of Maniacal Excitement, and in which after death there was found to be extensive internal hæmorrhagic pachymeningitis, by Drs. Savage and Percy Smith; Clinical Notes on Hæmorrhages, by Dr. Savage; Counter-irritation in General Paralysis, by Dr. Pritchard Davies.

Danielsson and Co.'s Clinical Publications.—We have received from Messrs. Danielsson and Co., of Southampton-buildings, Chancery-lane, some specimens of Charts, &c., which they have published. No. 1 consists of a series of outlines of bones upon which the surgeon can mark the seat and direction of fractures, excisions, &c. Included among them are accurate outlines of the skull, with the cerebral convolutions marked, after Féré. These are very useful, and save much time both in making and in referring to notes of cases. No. 2. A series of clinical figures and outlines, consisting of the surface of the body, back, front, and laterally; of individual parts, as the scalp, face, head, hands, feet, larynx; of the brain, entire and on section; of the retina; of the thorax, thoracic, abdominal, and pelvic organs. They are all carefully done, and are of real service in the record of cases. No. 3. A Pocket Case-book. Each page contains a small temperature chart, with appropriate space for history and description of the case. The book can readily be carried in the pocket, and yet the pages are not too small to be of use for short records of cases. Careful practitioners will find it of real assistance to them.

The Medical Chronicle. Vol. II., No. 12.—This valuable Chronicle still keeps on its way, and maintains its original character. The current number contains three original contributions. The article on Enteroraphy, by Stanmore Bishop, is illustrated with a plate showing clearly the various methods of suturing wounds of the bowel. Dr. Leech's article advocates Paracentesis in Pericardial Effusions. Dr.

Digitized by Google

T. Harris has an article on a well-worn but still unexhausted subject—the Relative Value of Tests for Albumen in the Urine. The rest of the volume is devoted to abstracts of various papers on Medicine, Therapeutics, Surgery, Midwifery &c., Diseases of Skin, Hygiene, &c. This is, of course, the most valuable portion of the Chronicle, and its chief *raison d'être*.

Gaceta del Hospital Militar.—We have received from Guadalajara, Mexico, the first number of this new medical periodical. Its object is to promote the study of Mexican medical topography by collating and publishing the information acquired by the medical officers of the army respecting the various regions in which they are called to serve, and the diseases peculiar to and most prevalent in them. It is also intended to turn to account the opportunities for clinical observation afforded by the military hospitals. In the present number of the Gazette a return of the military hospital of Guadalajara for the month of October is given, showing the admissions, deaths, discharges, and patients remaining in hospital, but as there is no statement of the strength of the troops to whom the return refers it is of comparatively little value. We trust that in future returns this important information will be given. The present return shows a very great prevalence of venereal diseases, forty-three out of a total of 106 admissions into hospital having been caused by them. A history is also given of an epizootic of acute enteritis and colic among the horses and mules of the artillery immediately after the removal of the company from Guadalajara to Juares. Among 103 animals there occurred, between Aug. 5th and Nov. 2nd, six cases of acute enteritis and twenty-seven of colic, and of the latter five proved fatal. The disease is attributed to the change of climate and of food, but there appears to be some reason to think that it may have been in some degree due to the quality of the maize, which constituted the most important part of the forage. We wish our new contemporary a long and successful career.

HEALTH OF BOMBAY.

THE nineteenth annual report by Surgeon Davidson, the acting health officer, on the health of Bombay during the year 1884 shows the mortality to have amounted to 27·29 per 1000, that of the males being only 25·29, while of the females it was as high as 34·96. Although this is lower than the death-rate of 1883, it is above the average of the preceding five years. Fevers caused 6830 deaths out of a total of 22,542; pneumonia and bronchitis, 3364; phthisis, 3083; infantile convulsions, 1980; diarrhœa and dysentery, 1716. Cholera did not prevail to any extent during the year, only 576 deaths by it having been reported, mostly between the ages of fifteen and fifty. There were only 18 deaths returned under the head of enteric fever. A series of tables is given showing the number of deaths from different causes among persons employed in different occupations, but as there is no statement of the numbers living of each class, the information is of little value. Much has been done of late years to improve the sanitary condition of Bombay, but it appears from Mr. Davidson's report that there is still great need of legislation in this direction. He states that the Municipal Act affords little or no protection against the erection of most insanitary dwellings, some of which are "dark, unwholesome dens, into which the light of day never penetrates, and which must of necessity breed disease and pestilence. ..... A privy is occasionally built inside a house and overhanging a well; on another occasion a similar structure is built within three feet of a well of drinking-water, and a drain is constructed to carry sewage within a foot and a half of the same well; a privy is built or rebuilt underneath inhabited rooms, and yet, notwithstanding the self-evident danger to the public health arising from this, and that such arrangements are opposed to the most rudimentary principles of sanitation, so accustomed have people in Bombay become to them that I have been gravely informed by otherwise fairly intelligent men that such contrivances are unobjectionable. In such cases it is hopeless to argue and useless to make any comments." The condition of many of the cemeteries is very unsatisfactory; they are overcrowded, and some of them are reported to be in a disgraceful state and a source of danger to the public health. The smoke nuisance is beginning to receive attention in Bombay, and it is hoped that effectual measures may be taken for its abatement. The water-supply, especially of the outlying districts, is very inadequate, and, as a consequence, is eked out from wells, the purity of which is often more than doubtful; but steps are now being taken for an increased supply. Attention is called in the report to the need of some system of medical relief for the poor at their own homes—something similar to the Poor-law Union medical system in England. At present no such provision seems to exist; and the very poor, unless they are able to attend at one of the hospitals or dispensaries, are left, when ill, without medical advice, except during the prevalence of epidemic cholera, when special arrangements are made to provide medical attendance for the people at their own houses. This seems to be a subject deserving of the attention of the municipal authorities. The registration of deaths in Bombay is stated to be still in an unsatisfactory state, and an appeal has been made to the members of the medical profession by the health officer for assistance in improving it by furnishing certificates of the cause of death in cases which they have attended—an appeal which, we trust, will meet with a cordial response.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION AND PAYMENT OF MEDICAL WITNESSES.

AT the meeting of the Council of the Poor-law Medical Officers' Association, held at their rooms, 3, Bolt-court, Fleet-street, on the 5th inst., that portion of the report of the proceedings at the winter assizes at Cork on December 11th, 1885, was read, from which it appeared that Mr. Justice O'Brien had said he had received a letter from Dr. Pierce of Newcastle, County Limerick, who complained of having received only £6 odd for his attendance at the assizes. He stated that he claimed £3 3*s.* a day and 15*s.* each day for expenses, and that he had been allowed but £2 2*s.* without any expenses; so that he had received but half of what he claimed. It was his Lordship's intention to reply to him, stating his opinion that £2 2*s.* a day to a professional man who came from a distant place was a wholly inadequate remuneration. The Treasury were, no doubt, very great people, and of course it was the duty of persons holding official positions not to sanction undue extravagance and expense, but the Treasury must understand that he would not require the services of any medical man from the country at £2 2*s.* a day. He would not sanction it, and he would treat as contempt of court any attempt to dispute the carrying out of his orders by the Crown solicitors.

The reading of the Judge's observations was received with much satisfaction by the members of the Council present, some of whom stated that they had been subpœnaed as witnesses in criminal cases, and had only been paid £1 1*s.* a day, and if kept from home all night, 3*s.* 6*d.* additional, out of which they had to pay hotel expenses, and for the services of a deputy whilst absent; and a feeling was expressed that the time had arrived when determined resistance should be made to such injustice. It was also proposed that the best thanks of the Council should be given to Mr. Justice O'Brien for his remarks on the case of Dr. Pierce and for his determination to give effect to his views, which, on being put to the vote, was carried unanimously. It was likewise decided that steps should be taken to memorialise the Treasury thereon, and the co-operation of medical members of Parliament was requested in such memorial. It was further proposed and carried that a report of the proceedings of Council and a copy of their resolution should be sent to THE LANCET, *British Medical Journal*, and the *Medical Press and Circular*, and that the editors be urgently requested to support the claim of Poor-law Medical Officers and others to a higher scale of payment when subpœnaed by the Crown in criminal cases.

THE LANCET.

LONDON: SATURDAY, JANUARY 16, 1886.

AMONGST the many interesting articles which are contained in the first number of the *International Journal of the Medical Sciences*, a notable place must be assigned to the paper on Bronchial Asthma, wherein Sir ANDREW CLARK reproduces in his customary logical manner the arguments which seem to him to annul the commonly accepted doctrine of bronchial spasm, and to favour that of temporary vascular turgescence of the mucous membrane as being the essential cause of the asthmatic paroxysm. He introduces the subject by a consideration of the phenomena of hay fever, between which affection and bronchial asthma he draws a close parallel. In the first place, he points out that Dr. BLACKLEY'S theory of the production of hay fever through the action of pollen upon the nasal mucous membrane is inadequate to explain the occurrence of the affection under the varied conditions of season and environment in which it often arises; whilst there appear to be many other exciting causes of an attack than the one alleged by Dr. BLACKLEY. These considerations point, he thinks, to the operation of two factors—a local or constitutional predisposition and an exciting actual cause,—the prominent feature in almost all cases being a neurotic temperament or constitution. The symptomatology of hay fever points clearly to a hyperæmic condition of the nasal mucous membrane, and the fact that hay fever may alternate with paroxysms of bronchial asthma appears to justify the conclusion that the two affections are closely allied in their pathology; for he can see no ground for concluding that spasmodic asthma, apart from nasal symptoms, should have an origin differing from the attack that occurs in such association. The features of the asthmatic paroxysm, and their explanation by the theory of spasmodic contraction of the bronchial tubes, are stated freely, and each point in the argument subjected to criticism. In the first place, it is held that although the bronchial muscles are capable of slow and limited contraction, yet there is no proof that they can contract with the suddenness and completeness required to produce the severe dyspnœa which marks the paroxysm. Then it is very doubtful whether the bronchial tubes could contract in opposition to the violent inspiratory efforts which dilate the thorax; and it is shown that the "alleged spasms are most common where the circular muscles are least abundant," for if the terminal bronchioles were contracted, the lungs should be collapsed rather than distended. The absence of proof that the physical signs are produced by such spasm, and the variability in pitch and situation of the stridor, with hindrance to the entrance of air, seem also "to be incompatible with any just notion of the contractility of the bronchial muscles, which is slow, persistent, and progressive."

These, and other difficulties in the acceptance of the commonly received doctrine afford certainly an opportunity for the introduction of a theory more in harmony with the facts. Such a theory is, in Sir A. CLARK'S opinion, to be found in the comparison he has instituted between hay fever and asthma; and he concludes his paper with a series of propositions which embody this doctrine—views similar, he tells us, to those propounded by WEBER in 1872, but which he has himself taught for twenty years past, and which he placed before the profession in an address at the Cambridge meeting of the British Medical Association. These propositions are so tersely stated that they will lose, we fear, by any condensation; nevertheless, it may be stated that they declare asthma to be a neuro-vascular trophic disease, depending upon a "special vulnerability of the respiratory mucous membrane, of the respiratory nerve centres, and of certain portions of the sympathetic." The nerve discharge may be excited by stimuli arising in the blood or any of the mucous tracts, especially the respiratory, in cutaneous inflammations, and in the central nervous system. The theory explains the phenomena of the paroxysm by the occurrence at first of more or less diffused hyperæmic swelling of the bronchial mucous membrane, succeeded by the development of circumscribed congestive swellings, which are more or less fugitive, and resemble the urticarial wheal; the secretion upon these swellings, at first viscid, and then freer and more copious, explains the varying auscultatory signs; and it is admitted that the acridity of the secretion may excite some contraction of the bronchial muscles. The hindrance afforded to the entrance of air excites exaggerated inspiratory efforts to overcome this difficulty, but expiration is less effectual; so that as the paroxysm proceeds the lungs become more and more distended, the subsidence of the attack being brought about by secretion from the mucous membrane and exhaustion of the respiratory and vaso-motor centres.

Although this doctrine of asthma is not propounded for the first time, it has seldom been so clearly and forcibly put; and the unbiased physician will find that there are many clinical facts in support of its conclusions. At any rate, it affords material ground for a reconsideration of the phenomena of this remarkable affection. The main difficulty in the way of the neuro-vascular theory, as opposed to the spasmodic, is the suddenness of the onset of the paroxysm; but that, indeed, is held by Sir A. CLARK to be opposed even more strongly to the view of bronchial spasm, which he contends must occur slowly and gradually. The extremely variable circumstances which surround the occurrence of the asthmatic attack, and the equally remarkable facts as to prophylactic and remedial treatment, may perhaps be as well explained upon the one view as the other; for by either doctrine we are compelled to refer the root agency to the nervous system, and especially to reflex excitation through a hyper-sensitive respiratory tract. Asthma is, in point of fact, a neurosis; but whether the efferent stimulus travels by way of the pulmonary plexuses to the bronchial muscles, or operates through the vaso-motor centre upon the bronchial bloodvessels, is the debatable question. Nor can we think that much gain towards the solution of the problem is derived from the effects of treatment. There is hardly a disease in nosology which has been submitted to so much empirical treatment or which is so capricious in its response to remedies. We may, for instance, fail to see why congestive swellings of the bronchial mucous membrane

Digitized by Google

should subside under the influence of the inhalation of the fumes of nitre, or tobacco, or stramonium, and may conceive that the great relief afforded by a hypodermic injection of morphia is more consistent with the relaxation of spasm than the free outpouring of secretion from the congested mucosa. In some cases, too, relief is given by the inhalation of nitrite of amyl, which theoretically should be conceived as tending to aggravate a hyperæmic state. But the truth is that our knowledge of the physiological mechanism is at present too imperfect to explain many apparent inconsistencies in the action of remedies, and it is unsafe to argue too finely upon such a basis. The parallel sketched by Sir A. CLARK between "hay asthma" and "bronchial asthma" is, however, perfectly legitimate, and it certainly gives scope for thought and observation.

DR. WILLIAM FARR, in a contribution to the Registrar-General's Fifth Annual Report, issued more than forty years ago, deemed it necessary to point out the fallacy necessarily involved in any attempt to base conclusions as to the sanitary condition of populations upon the observed "mean age at death" occurring therein, because he "found that the error had survived and assumed new forms very much calculated to mislead." In spite of Dr. FARR's long-continued efforts to develop a sound system of vital statistics, it is disappointing to find that the fallacies he so constantly exposed still survive and are often endorsed by authorities generally accepted as experts. The President of the Metropolitan Association of Medical Officers of Health, in a report he has recently issued upon the health and sanitary condition of St. George's Hanover-square, has given statistics of the mean ages of persons dying in his district and its registration sub-districts during 1884, and incorrectly refers to these figures as "the mean duration of life." The correct use of terms is essential to the progress and utility of all branches of science; and whether or not the claim of statistics to rank as a science be admitted, it is essentially necessary to avoid confusion of terms in writing on this subject, in order to guard against the causation of fallacious deductions. "Mean duration of life" is an abstract term, signifying the mean duration of life in a theoretical or life-table population, and is equivalent to the expectation of life at birth in such a population. Mean duration of life, calculated in this manner on a life-table basis, is the only scientific and thoroughly sound test of the true sanitary condition of a population. When, however, the term "mean duration of life" is incorrectly used to denote the mean age of the persons dying in any ordinary population in which the births exceed the deaths, an entirely false impression is conveyed, as the mean age at death in such populations is worse than useless as a test of its comparative health or sanitary condition. It would be difficult to find a better example of this form of fallacy than that presented in the use of the mean age at death of those dying during 1884 in the three registration sub-districts of St. George's, Hanover-square—statistics which have been widely reproduced, with or without comment, by our lay contemporaries. The report states that whereas the mean age at death (falsely called the "mean duration of life") in the whole of London in 1884 was 38·08 years, it was equal to 49·78 in Belgravia, 62·92 in Hanover-square, and 72·70 in Mayfair—sub-districts of the district of St. George's, Hanover-square. Assuming these mean ages at death to be correctly calculated (although we cannot avoid a suspicion that the mean age at death in Mayfair takes account of all the deaths of the aged poor in the workhouse), we do not hesitate to characterise the figures as entirely misleading if accepted as even indicative of health condition. It is only necessary to refer to the varying birth-rate as evidence of the widely different age constitution of the populations. In Greater London the birth-rate in 1884 was 34·9, while in the district of St. George's, Hanover-square, it was only 21·18; it was 23·87 in Belgravia, 16·46 in Hanover-square, and 15·20 in Mayfair sub-districts. The Census Report gives more direct evidence of the wide variations in the ages of the populations of these sub-districts in 1881, and it is needless to say that the mean age of those dying is mainly dependent upon the mean age of the living. In London 13 per cent. of the population were aged under five years, while in St. George's the proportion was only 8·3. It was 4·7 in Mayfair, 7·0 in Hanover-square, and 9·5 in Belgravia sub-districts. Similar variations occur in the proportions of the population aged upwards of sixty years, which was only 6·3 per cent. in the whole of London, whereas it was 14·1 per cent. in Mayfair sub-district. With such facts before us, it is not possible to doubt that Dr. FARR was right in pronouncing (in the article above referred to) that to take the mean age at death to represent the mean duration of life is "absurd and misleading." It is, however, still necessary to urge upon all medical officers of health to avoid the use of this false, though temptingly easy, method for measuring either the longevity or the health condition of a population.

WHAT is "depressing weather"? It seems enough to say that when the conditions of temperature, light, and atmosphere are such as to make the average mortal feel miserable the weather is depressing. As a matter of fact, however, this paraphrase is no more a definition than the affirmation that life is evidenced by some "form of motion"—in a technical sense—defines life, or even affords the least intelligible notion of what it is, and in what it consists. So is it with the colloquially coupled words "depressing weather." Only cause and effect are named; nothing whatever is said or even implied as to the *modus operandi* or process by which the result is obtained. Without attempting to discuss the question involved exhaustively, it may be worth while to point out two or three of the more prominent considerations which it is important to note. There are manifestly three particulars of the general effect of depressing weather that may be usefully studied apart. Thus: the effect produced by external conditions on the temperature of the body, at the surface at least; the effect on the blood-pressure generally and the air-pressure in the lungs; and the effect on the nerve-state, with the secondary influences exerted on or apparent in the tone of the muscular system. It is, of course, impossible to go into these matters at all in detail. Suffice it to make the following observations by way of suggestion. If the surroundings be such as to abstract heat without at the same time stimulating the organism to a greater or quicker "evolution of caloric"—to use an obsolete but convenient

Digitized by Google

expression—there must needs be a gradual lowering of the vital heat on which, as we know, the energy depends. Although it would not be accurate to assert that the convertibility—for convenience of expression—of the terms *heat* and *force* in relation to the organism implies that these two forms of motion are actually correlative, it is nevertheless a fact, that where there is any defect of bodily heat by reason of deficient production, there is sure to be "depression" as a consequence. As a matter of experience, we know the difference from feeling cold as a healthy man may feel it in bright weather, without the least loss of energy, but rather a quickening and enlivening of the animal spirits; and "feeling cold" as it is felt when the life seems to be chilled and the heart sinks with oppression and misery, the very "mind" and "senses" being, as it were, numbed. This subjective difference between the two states is due to the deficiency of bodily heat resulting from different causes: on the one hand, rapid abstraction by the surroundings with stimulation, as on a bright cold day; and, on the other hand, loss of heat without stimulation when the surroundings are cold without being invigorating. Another point of moment as regards heat relates to the manner in which it is distributed. The temperature of the blood may, as is well known, vary, under different conditions of the body-state, in the several vessels, from 98·6° F. near the surface, to a much higher point in the deeper parts. The surface temperature is generally below the figure stated, and immediately underneath the skin it probably often falls to a point still lower, just as it may rise in certain maladies—e.g., erysipelas or scarlet fever—to a temperature at the surface far above that in the deeper vessels. Obviously, if there be a tendency to depression of the nervous tone, any disturbance of equilibrium between the surface and the deep parts of the organism must be embarrassing, and therefore exhausting, when there is no proportionate stimulation or excitation of the heat-producing faculties and processes. Blood-pressure and air-pressure, both, together and apart, are important factors in the general state, and are physically and chemically influenced by the weight, temperature, and oxidation of the atmosphere. The nervous system is acted upon through the mind and senses, and—which is too often forgotten—by the electrical state of the earth and our surroundings generally. There seems reason to suppose that a "heavy," "depressing" state of the environment means, in part at least, a condition in which electricity is absorbed from the earth and held in the clouds at the periphery of the *practical* atmosphere, with the result that the earth, or a portion of it, and the organisms upon it, are deprived of their normal residuum of static electricity, as before a thunderstorm, the electricity being regained only after "the storm that clears the air"—to use a popular expression,—when, in fact, the electric fluid has been returned to the earth in the form of lightning or been carried back to it by the rain. "Depressing weather" is a state, or a number of states, in which an effect, in great part physical and in lesser part mental, is produced on the animal organism through the media of temperature, blood-pressure and air-pressure, nerve tone, and electrisation. Some organisms are more susceptible of external impressions than others, and these are the most susceptible of the injurious influence which depressing weather exerts. The indication with a view to self-defence or remedy is obviously to render the mind and body as little responsive as may be to external conditionings, by giving it a force and momentum of its own. This force and momentum are only to be created by voluntary energy and healthful exercise.

IT is difficult to keep from despair as we once more ask the question, When will the greatest nuisance of England cease—when will the Thames be relieved from the disgusting pollution which now renders it a cesspool throughout its tidal region? Of the existence of a tremendous nuisance, and of the urgent danger to which it exposes the metropolis, there is no longer any room for doubt. Hard as the Metropolitan Board of Works fought, they were utterly crushed by the evidence brought before the late Royal Commission and by the stinging words of the Commissioners in their reports. They have, indeed, practically admitted the whole case against them by adopting a costly system of disinfection, which could only be justified by urgent necessity. The disinfection, it is true, is a sham, utterly useless, and a gigantic waste of the money of the ratepayers; but it is none the less a confession of the existence of a nuisance created by the Board, and for many years defended by them as a public blessing.

Time passes quickly, and the world is apathetic. We are in the winter, and the river does not smell, although we know that it is fouler than ever. Why should anyone trouble about it? People are tired of the subject. We ourselves confess to the weariness which the constant reiteration of admitted statements is sure to engender, and our readers, trained though they are to the duty of persistent denunciation of sanitary abuses, no doubt share the feeling. But it is just at such a time that renewed energy is wanted. Surely the Parliament of England cannot be quite blind to the urgency of the peril to which London is exposed? There is always danger in such contempt of sanitation, but just now, with cholera almost at our doors, it is of the gravest kind. We have had the cholera before, and it has slain its thousands, and we have no possible right to assume that we shall not have it in London next summer. In that case our river will be a natural centre of infection, and as in the recent epidemic in Spain, so here, the disease will be likely to follow the course of the foul river.

What ought to be done and who ought to do it? These are the questions to which immediate attention must be given if we wish London to be safe next summer. It is not for us to propound engineering schemes, or to dictate which among the many possible remedies should be applied. But this much we may safely say: Instant preparation ought to be made for the purification by precipitation of the sewage at the outfalls, and for taking the sludge, properly protected, to the lower reaches of the river, where, applied to the land, it would have a certain though not great value, and would do good rather than harm. Meantime, a complete scheme should be prepared in accordance with the recommendations of the Royal Commissioners for carrying the sewage of all London, including what is known as the Lower Thames Valley, down to Sea Reach, where it could be purified, the solids applied to the land, and a clear effluent

Digitized by Google

thrown into the river. This would cost money, but not more than London could well afford.

Such vigorous action as this, which is substantially the same as that urged by Lord BRAMWELL'S Commission, cannot be expected from, and will certainly not be attempted by, the present Board of Works, whose whole desire in this matter appears to be to find how best "not to do it." Possibly they are trammelled by their distinguished engineer, who, although a great benefactor to London in the past, now seems to pose as a mere obstructive. He has so often repeated his belief that the present system is sufficient and satisfactory, and requires merely some expansion, that he can hardly be zealous in any work of real reform.

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF LONDON.

CONVOCATION of the University of London meets on the 19th inst., and the number of resolutions upon the agenda paper is unprecedentedly large—viz., sixteen. The most important of these refer to the Matriculation Examination and the adoption of a revised syllabus which has been prepared by the annual committee. Mr. Hawkins Jones, LL.B., proposes to move a resolution to the effect that an original printed thesis, with examination thereupon, should, as in the D.Lit. and D.Sc., be required of candidates for the LL.D. and M.D. instead of the existing examinations. Mr. Tyler and Mr. Spratling each give notice of long motions affecting the constitution of the University; and Dr. Grece proposes to rescind the vote of the last meeting suspending one of the Standing Orders as being irregular and a breach of Standing Order No. 11.

THE PROPHYLAXIS OF HYDROPHOBIA.

AT the Epiphany Sessions for the County of Surrey last week, the Earl of Onslow—who is the President of the Temporary Home for Lost and Starving Dogs at Battersea—made some forcible and timely remarks. Referring to the circular issued from Whitehall, he said it was unfortunate that the orders could not be put in force by that Court, instead of each separate authority. As an illustration, he mentioned that the Chief Commissioner of Police within the metropolitan area had issued most strict regulations, and although some advantage must be derived therefrom, it could not be conclusive, for a dog had only to come up from the county of Surrey, and was at liberty to bite as many people as it liked until caught. It was well known that rabies and hydrophobia had been very prevalent in Surrey since 1883, and he hoped, therefore, this letter or circular would be brought before the petty sessional divisions in strong terms, and that they would see their way clear to carry out regulations similar to those in the metropolis, and to get them extended to the whole south of England, otherwise no good would result from the stringent measures in the metropolis. Mr. Gordon Clark pointed out the uselessness of the county divisions carrying out the regulations unless the local authorities in the boroughs and towns did the same, and the Chairman, Mr. E. H. Leycester Penryhn, having said that the powers could not be put in force unless there had been a mad dog in the district, it was, after a short discussion, resolved that the clerk should send a copy of the circular to all the authorities in the county. We could wish that all the county, borough, and town authorities had it in their power and were willing to enforce regulations similar to those now carried out in the metropolitan district. There can be no question that it is possible to stamp out hydrophobia in this country. It is emphatically not a necessary evil. Unfortunately, however, it is the fashion to have now and then what is called a hydrophobia "scare," which soon begins to flicker and dies out, while no real efforts are made to render this most terrible disease a thing of the past. Unfortunately, too, directly the police authorities endeavour to take some action the papers are flooded with letters which, though well meant, are, we cannot help thinking, a great deal too highly tinged with sentiment run riot. We yield to none in our love for animals, and especially for dogs, but surely the saving of, say, six or seven human lives each year from death by hydrophobia is of infinitely more consequence than the temporary inconvenience of the whole canine race. The use of muzzles nowadays is not necessarily cruel. Indeed, we think that, if the dogs could be appealed to in the matter, the more intelligent, and may we say representative, of them would agree that as the wise and thoughtful of the human race accept the inconveniences of vaccination to save them from the perils of small-pox, so they should cheerfully endure the temporary troubles imposed by the muzzle, and escape all risk of the sufferings of rabies. We trust that the remarks of Lord Onslow, who is a well-known lover of dogs and a master of hounds, will not pass unheeded. M. Pasteur may be on the right tack, the Russian vapour bath treatment may prove of some use, but it cannot be denied that prevention is infinitely better than cure. We regret to see it stated that the present police regulations in the metropolis with regard to dogs will be withdrawn on the 17th of this month, when the term of sixty days will have expired. Half-hearted measures are never likely to prove successful.

ICE ACCIDENTS.

ICE was, but is not when we write; it may or may not be again. Of all the changeful circumstances and conditions of this changeful world and scene, and especially this most fickle climate of ours, the weather is the least to be reckoned with or counted upon. Ice "accidents" are, in a way, the leading features of the experience we have of ice in this country. Only a passing feeling of regret, mixed with a little grim amusement is awakened, when we hear of a hundred or so of persons being immersed. When a serious immersion occurs, it is necessary to treat the case as one of proximate drowning *plus* refrigeration, not so much from being plunged into the water below the ice, which, although cold, is not greatly colder than uncovered water under ordinary conditions and in average cold weather, but because the immersion occurred at a moment when the body may perhaps have been either already chilled from standing about or exhausted by exertion. Looked at from a physiological point of view, possibly, the precise moment when a man or woman is skating with energy is not a bad time to plunge into cold water, but the immersion should be rapidly performed and ended, and there should be no fright. Taking things as we find them, it is not wise to "go under" at such a time. For the half-drowning of an ice-accident, rapid removal of the wet clothes, brisk rubbing of the surface to restore capillary circulation in the skin, and prompt wrapping in hot blankets, are the best measures. It is also well to give, as soon as possible, a moderate drink of hot tea or milk-and-water—not spirits, as a rule. Coffee is better after reaction has fairly set in than at the moment of rescue, or there may be headache. If the immersion has endangered life by drowning, of course matters must be treated on general principles, and among the most important things to remember is the fact first pointed out by Dr. Benjamin Howard of New York, that the proper anatomico-physiological way of opening the air-passages is not to drag the tongue out but to raise the jaw, closing the mouth.

Digitized by Google

The act of clenching the teeth forcibly is really the last act of life in ordinary death, and is a natural instinctive effort to facilitate inspiration. The aids to respiration by manipulation of the thorax and arms are well understood and explained by the Royal Humane Society. Speaking generally, the chief points to note about immersions from ice accident are the special need of very promptly restoring warmth, and the urgency of the demand for friction of the surface to restore cutaneous circulation, thus promptly relieving any congestion of the internal organs which may have occurred in the moment of "chill" or during the subsequent collapse.

THE VACANT PRINCIPALSHIP IN ST. ANDREWS UNIVERSITY.

MUCH wonder exists why the Government is so slow in appointing a successor to the late Principal Shairp in the University of St. Andrews. As St. Andrews is now becoming an important science centre, and as science degrees from it are open to students of the University College at Dundee, a Principal within the University, who should represent the superintendence and interest of natural science, is specially needed. The cause of delay would be less difficult to explain if there were no eligible candidate for the post, but with the fact that Dr. Bell Pettigrew, F.R.S., the Chandos Professor of Medicine, is a candidate, and that he is heartily supported on all sides as one who would fill the office with the greatest distinction and with all the zeal he has ever shown for the University, the difficulty of finding the right man for the right place cannot be the real one. It is more probable that the weight of other and pressing labours has prevented the Duke of Richmond and Gordon from settling this appointment, which, though perhaps minor as an affair of State, is still very important to an immense number of the highly intellectual members of the community. For ourselves, we should rejoice to see the eminent representative of our own profession to whom we have referred selected for the office, and we are sure our whole fraternity would join with us in congratulating him on obtaining a distinction so well earned, and so entirely harmonious with his abilities and trained preparation for its duties.

THE FOCI OF CHOLERA IN SPAIN.

As cholera still prevails in Spain, there is every reason to fear another and serious outbreak next summer. For the protection of Europe, which would then be exposed to contamination, as well as for the sake of the Spaniards themselves, every organ of public opinion should enter a protest against the incapacity or inactivity of the authorities. One of our correspondents recently visited all the principal centres where the cholera had wrought the greatest havoc. He carefully examined the various local foci of disease. Both the Spanish press and Government officials laid particular stress on what they called the focus of disease—i.e., some particular slum or slums which constituted centres from which the epidemic spread to various parts of the town. This being the case, it was natural to expect that special measures would be taken to improve the condition of such pernicious localities. Nothing of the sort, however, has been done. Houses were whitewashed, cleaned, and fumigated; disinfectants were thrown down the drains; and that is the most that can be said. But the temporary removal of a little superficial dirt will not improve the sanitary condition of a dwelling; indeed, the houses of the poor in the large towns of Spain are cleaner than those of England. The bedding, the floors, and the furniture are more carefully washed, dusted, and kept than will be found among the poor of London and the great English towns. It is only when we approach the sanitary contrivances that we find a distinct difference. The untrapped closet, just outside, when it is not in the very middle of the kitchen, is a most common occurrence in Spain. From the kitchen sink a large pipe goes to the closet-pipe, and all the sewer-gas has free access to the cooking utensils and the food. In cholera localities these and many other equally obvious defects exist, and it was found that a large proportion of the cases occurred in rooms where there was no window at all. In other rooms the principal ventilation was received from a foul closet just outside the door. It is therefore indispensable to secure at once the proper ventilation of sleeping apartments and the necessary alteration in the construction of the closets, together with the trapping of all drain-pipes. The larger questions of town drainage and water-supply cannot be solved so promptly. But, in the name of humanity, we have a right to demand that the smaller though no less urgent reforms indicated above should be immediately carried out. So large a portion of Eastern and Southern Spain has now been invaded by cholera, that it is easy, acting on the large experience already acquired, to select in the, as yet, exempt districts to the west of the peninsula, towns and localities that present similar topographical and general conditions. In such places, at least, a large number of inspectors must be appointed, and they should commence at once a house-to-house visitation, for the purpose of detecting and altering those structural defects which, in the towns of Granada, Valencia, Barcelona, Zaragoza, &c., were found to favour the development of cholera. This is the least which under the circumstances, can be done; and if this is not attempted Spain will merit the censure of European civilisation. In Portugal, also, the adoption of similar precautions will be found more efficient as a protection against the approaching epidemic than the sanitary cordons and quarantines on which the Portuguese Government at present solely relies.

"AN UNNECESSARY POST-MORTEM."

A CLERGYMAN has published a letter commenting on what he describes as an "unnecessary post-mortem," with the object of informing the public of "their rights" in similar circumstances. The facts were as follows. The child of a labourer, aged two years, died very suddenly. An inquest was required by law in order to ascertain the cause of death, and the coroner, in the ordinary course of his duty, requested that a post-mortem examination should be made. The parents objected, and the clergyman supported them in their objection. According to his statement no suspicious circumstance attended the death. The refusal of the child's parents to have the body examined, he says, perhaps with good reason, did not in this case afford real ground for suspicion. The examination was made as usual, and the verdict proved that death was not due to unfair means. Some of the statements made in this letter cannot be passed over without remark. The writer has written it with the intention of challenging the administration of the Act which regulates the holding of inquests, and his opinion is that the law has in this instance been injuriously applied. The section of the body was in his opinion a harsh proceeding, because it contravened the wish of the parents. He claims that this was a case in which mercy and consideration should have been shown by deference to that wish. His own feeling with respect to this question appears on general grounds quite justifiable. We can understand and appreciate it as an impulse natural and creditable to humanity. At the same time, every citizen must be prepared to allow some sacrifice of personal feeling on a question of public security. Such a question is that now before us. On our own part, we are convinced that the public opinion of past times has not been misguided in entrusting the decision of such matters to the judgment of a coroner's jury

Digitized by Google

and medical witnesses. Coroners are by no means too fond of ordering post-mortem examinations. If consulted, instead of being opposed by the relatives of the deceased, they are probably as reasonably sparing of family feelings as conscience will allow them to be. The final statement of this remarkable letter states that the rich have an advantage over the poorer classes practically, if not theoretically, in the application of the law of inquests. This advantage consists in the possession of the power—i.e., the means—of maintaining an objection in a court of law. In reply to this, we have only to say that, whenever the point of right is raised in such a case, the rich plaintiff will find himself, like his poor brother, a loser in the end, and superior in nothing but in having the power to raise a needless scandal.

HYALINE PROSTATIC CASTS.

THE paper read by Sir Andrew Clark at the last meeting of the Clinical Society may prove an interesting contribution to our knowledge of the clinical examination of the urine. Hitherto, we believe, the existence of hyaline cylindrical casts in the urine has been held to be conclusive evidence of the presence of some form of renal disease. And we suspect that a proposition embodying that information would still be regarded as of the greatest value from a practical point of view. It is, however, possible that hyaline tube casts may come from the mucous glands of the prostate, and the presence of flask-shaped bodies, probably moulds of the inner ends of the mucous glands, would no doubt give a kind of evidence in support of the prostatic origin of such casts. The case that was specially narrated by Sir Andrew was one in which, according to the author's own statement, the urine was healthy, with the addition of a small quantity of albumen. The evidence that was adduced in favour of the prostatic origin of the hyaline casts was no doubt of a strong character, though not to our minds absolutely convincing. Some further interesting information, culled from a clinical examination of the urine, was also forthcoming from Dr. Greenfield. He has found in a few urines bodies having much the appearance of corpora amylacea, and in one post-mortem examination it was proved conclusively that these bodies were present in the kidneys.

THE PRESERVATION OF LIFE ON THE CONGO.

THE heavy mortality of the Baptist missionaries who have done so much for both science and the missionary cause in the vast regions of the Congo basin is a matter of much concern to all who wish to see religion and commerce established in these parts. It is hoped that a few medical men will be induced to offer themselves for medical service at the mission station. Meantime a very kind and useful service has been rendered to this cause by Dr. Prosser James. He has addressed a series of familiar letters to the Rev. T. J. Comber, entitled Health on the Congo, and intended for circulation under the direction of the committee of the Baptist Missionary Society. We have read these letters, and think them calculated to be of the greatest use to the missionaries. They are written in an easy style, but they embody good descriptions of the principal diseases of tropical countries, and an excellent and discriminating account of the best treatment, which cannot fail to be valuable to missionaries and others in the absence of medical aid. Dr. James has not restricted himself to a mere account of the diseases likely to be met with and their most appropriate treatment, but has devoted several preliminary letters to such questions as the position of stations, acclimatisation, malaria, soils, houses, personal hygiene, clothing, work, exercise, rest, sleep, food, digestion, &c. It is evident that much of the promotion of health of Europeans in such regions will depend on an intelligent knowledge of the questions discussed in these preliminary letters, which give with much clearness just the kind and amount of information likely to be useful. Mr. Stanley, it is well known, has spoken as if the missionaries and not the climate were at fault. This is scarcely the case, though Mr. Comber himself admits that the high mortality has been chiefly due to overwork, imprudence, and want of proper medical treatment. With the admirable physiological and medical lessons conveyed in these letters and in the notes of Mr. Comber, there will be less chance of, and certainly less excuse for, the operation of these factors in future, and we cordially commend them to the thoughtful study of all persons labouring in the great field now opening up on the Congo, and as particularly appropriate in the case of the countrymen of Bruce, Winterbottom, and Livingstone.

TONSILLITIS.

THE *Journal of the American Medical Association* contains an account of a discussion on Tonsillitis and its relations to Diphtheria and other diseases, on a report of two hundred cases by Dr. J. M. G. Carter, of Waukegan, in the Chicago Medical Society. The author attributed the majority of cases, which he said occurred in March, April, and May, to north-east winds containing an excess of ozone, and to unusually disturbed electrical conditions of the atmosphere. His notions of the relations of the disease may be gathered from his division of the cases into three groups—simple, diphtheritic, and scarlatinous. He considered, however, that cases of simple tonsillitis were often accompanied by attacks of diphtheria or scarlet fever among other members of the family. This is really the point to be determined. Few things are more common, especially in certain families, than follicular tonsillitis, with big tonsils and a red condition of the fauces and pharynx. Occasionally one sees this condition affect several members of the same family, with more or less grave symptoms in one or more of them. But, except in certain districts, the cases are of a slight character, and are often attributable to cold and damp, sometimes associated obviously with a rheumatic diathesis, as was pointed out by several members in the Chicago discussion. It would be interesting to know from those practitioners who have seen much of recent diphtheria in London how frequently they have noticed simple follicular tonsillitis associated in the same house with cases of grave and fatal diphtheria, with characteristic exudations and albuminuria. One speaker in the Chicago discussion suggested that we should consider all cases of simple tonsillitis as malignant, which would be about as reasonable as to consider all cases of summer diarrhœa as cases of Asiatic cholera, or all cases of bronchial catarrh as cases of bacillary phthisis. There is much need for careful classification of tonsillitic cases, especially now, when we seem threatened with a revival of bad forms of throat disease.

DISCUSSION ON CHOLERA IN BARCELONA.

IN a paper read before the Barcelona Academy of Medicine by Dr. Sordé, giving his views on the lessons to be learned from the experiences of the recent cholera epidemic, the question of abortive treatment was entered into. When, during the existence of cholera, cases of diarrhœa occur, with frequent fluid stools and little or no pain, energetic treatment should be at once adopted. Laudanum should be given, and strict confinement to the bedroom enjoined. If there is frequent vomiting and severe gastric pain, drugs by the mouth are useless; so probably is medication per rectum; and even the absorbent power of the skin is often so slight that external applications are of little efficacy. The only plan then is to resort to hypodermic injections. The most useful drugs are the salts of quinine, amongst which the

Digitized by Google

author prefers the hydrobromide. Ether also is useful for setting up reaction. Subsequently tonic medicines may be given. The best nourishment for cholera patients is at first vegetable soup (in the case of children, Nestlé's milk food); afterwards meat soup without fat, and milk, and ultimately solid food, may be allowed. Cold water the author considers indispensable in all stages. He does not allow alcohol until convalescence. With regard to diagnosis, the author considers it impossible to diagnose cholera with absolute certainty unless the algide stage is reached. As to prognosis, he considers cholera less fatal than typhoid. In the discussion which followed, Dr. Suñé remarked that until the outbreak of this epidemic he had always considered that at such times diarrhœa should be looked upon as a premonitory symptom of cholera, but that now he knew that numbers of cases had occurred in Barcelona, which had got well by themselves, so that if all had been treated with opium the drug would have been credited with far too great a degree of efficacy. He referred to the case of a student who, being attacked by diarrhœa and having great faith in the ideas of Tunisi, took enough laudanum to render him narcotic; notwithstanding which cholera developed itself. Dr. Carré also believed that the efficacy of laudanum had been overrated, and referred to the case of a boy whose uncle had dosed him well with it, but who, nevertheless, developed all the symptoms of cholera. Dr. Fargas mentioned some observations he had made on the body of a man who had died from cholera which lasted only a few hours. Nothing remarkable occurred during the first hour after death, but at the end of that time movements were noticed in the legs, shoulders, and head, also fibrillar contractions in the arms. The temperature had risen to 40° C., and sweat was observed on different parts of the surface.

IRREGULAR DEATH CERTIFICATION.

IT is curious, notwithstanding the serious censure by the Medical Council of practitioners who sign death certificates in cases which they have not seen, but which have been seen by an unqualified person in their house, or in a house with their name on the door-plate, to see that both practitioners and unqualified persons are found to repeat the offence. Such a case has just been investigated by Mr. M. Browne, the borough coroner for Nottingham. It was that of an illegitimate child with measles, taken to Mr. Irvine's house by its mother, who there, according to the report before us, saw a gentleman whom she thought to be Mr. Irvine, but who proved to be a medical student, Mr. E. H. Maclure. He saw the child a second time and recommended that it be taken to a dispensary. He said he could wash his hands of the child. She sent for another doctor, but before he arrived the child was dead. She went for a certificate to Mr. Irvine's house, and got one written by Mr. Maclure, but signed by Mr. Irvine, who admitted he had never seen the case. He said he did not know the law was so strict. The coroner commented severely on the admitted facts of the case, and we cannot but regret that practitioners should be found to allow themselves to get into so indefensible a position.

ETIOLOGY OF TETANUS.

M. Lannelongue raised a discussion in the Society of Surgery of Paris, the 28th October ult., on the etiology of tetanus, still inclined to the opinion that it is sometimes endogenous. This view found little favour with succeeding speakers; but it was generally admitted that much uncertainty still prevails on the causation of tetanus. This is a disease worthy of being studied with the aid of comparative pathology. All our domestic animals, but more especially horses and sheep, are liable to tetanus after injuries. Army surgeons long since admitted the influence of climatic conditions in producing the disease, and interesting confirmatory evidence is supplied by Professor Robertson in his Text-book on the Practice of Equine Medicine (p. 407):—"That cold and exposure suddenly encountered have a determining influence in the production of tetanus we occasionally see exhibited on an extensive scale in the case of newly-shorn sheep, where, should a lowering of the temperature and boisterously wet weather immediately succeed the shearing operation, it is no uncommon circumstance to find a considerable number of animals, on the subsidence of the storm, suffering from tetanus. Horses clipped in cold weather, and incautiously exposed immediately afterwards, are also sometimes similarly affected; while one of the most commonly observed results of young animals being partly submerged in wet ditches, and remaining struggling in such a situation until completely exhausted, is an attack of tetanus."

SNAKE-BITES AND RABIES.

THE curious local traditions that are handed down from one generation to another are sometimes of much interest, and especially those bearing on the treatment of snake bites and other accidental occurrences likely to prove fatal. In some of the heath countries a general notion prevails that the bite of a yellow or black adder is best combated by the rubbing in of some of the fat of an adder, and also by giving some of the grease internally. A lay correspondent, referring to an article in last week's LANCET by Surgeon-Major Roy, suggesting that the poison of the cobra may prove to be an antidote for rabies, says that it is a curious fact that in Wales there is a belief among the common people that a dog that has been bitten by an adder will never be subject to hydrophobia. When Sir Thomas Watson was asked his opinion on this subject, he said, "I agree with you in inability to see how this could be proved; or how, if proved, it could be practically utilised for the benefit of the human animal; such traditions are, however, always worth preserving." In the course of a case tried before the Tribunal of Correctional Police in Paris, it appeared that the carcase of a dog that had been slaughtered on account of rabies was thrown by scavengers on to a dust-heap, where it was devoured by cats and rats. A great number of the cats in the neighbourhood of the places where the dust is shot from the municipal carts have been attacked with rabies.

THE PERILS OF FOOTBALL.

FOOTBALL, which seems to be degenerating more and more into a species of "free fight," has been the cause of another sad fatality. An adjourned inquest was held on Monday evening last at Bridgwater on the body of William Poole, aged twenty, who came by his death from injuries received whilst playing in a football match on Dec. 28th. As reported in the papers, it appeared from evidence that the deceased, who was playing a very fast game, slipped and fell, and at the same time received a severe kick in the chest (? abdomen) while several other players fell above him. Dr. Winterbotham deposed that death resulted from hæmorrhage arising from injuries accidentally received to the internal organs. It is satisfactory to add that the jury had the courage of their opinions, and, in returning a verdict in accordance with the medical testimony, strongly condemned football as a dangerous game, and deprecated the recklessness with which it is played. Can nothing be done to check this "recklessness" (as the jury somewhat mildly put it)? Mr. E. T. Sachs, a well-known athlete, recently wrote to us recommending lacrosse as an alternative game. Football, however, is in many ways a good game, and enjoys remarkable popularity. Surely, by some modifications it might be made also comparatively safe. At present there

Digitized by Google

can be no doubt that it is highly dangerous. If proof of this be wanted, it is furnished by the fact that this is at least the third fatal accident *directly due to football* already recorded thus early in the season. Some measures will have to be taken, for it must always be remembered that the actual sufferer is very often the breadwinner of the family, a fact which largely adds to the roll of football victims. Cannot our sporting contemporaries make any suggestions?

SOCIETY FOR THE EXTENSION OF UNIVERSITY TEACHING.

IN the Poplar branch of the above Society, Hygiene is to be the subject of the course during the next session, with Dr. A. H. Robinson as lecturer. The course will be opened on the 25th inst., when Dr. Richardson, F.R.S., at the request of the committee, will preside, and will deliver a short introductory address. Last year the subject of the course was History, the Marquis of Ripon giving the opening presidential address. The attendances throughout the year averaged as many as two hundred students. It is most gratifying to observe how much real good is being wrought by this useful Society for advancing university instruction. It is practically bringing the universities to the doors of the people. To Dr. Robinson we wish every success in his professorial and useful task for 1886.

THE STATE OF THE STREETS.

IT is not creditable to our intelligent self-government as a civilised people that year by year the first fall of snow finds us unprepared to clear the streets of the encumbrance. There would not appear to be any great difficulty, remembering the immense number of persons out of work at this season of the year, to send out into the streets at half an hour's notice an army of sweepers, who would make very short work of the heaviest downfall in, say, a couple of hours at most. Only the shovels and brooms need be close at hand; the carts could be collected at once if officers were empowered to issue the necessary instructions; and, instead of a great scandal arising, positive good might be done by giving the poor an honest and not unhealthy spell of work. The masters of workhouses should have orders to send all the tramps into the streets with brooms and shovels for work in gangs, under proper official supervision, instead of sending them into the stone-yards or oakum-sheds, and the able-bodied inmates of workhouses might be similarly employed. It only needs a general order and a standing organisation of the official staff, which could be set in action instantly. There is not the smallest difficulty in this, beyond the *vis inertiæ* of a clumsy and discordant system of administration. We do not need to talk of snow ploughs and rakes, and special collecting apparatus; brooms and shovels will answer every purpose, if only time be taken by the forelock and the obvious duty perceived and performed at once.

MEDICAL MEN IN THE WORKHOUSE.

THE public were scandalised a few days ago by a paragraph in the papers intimating that three medical men and a dispenser were in the Islington Workhouse. Most statements of this kind have an air of exaggeration about them, and from our inquiries we conclude that it is so with this particular assertion. But it is true that two registered medical men and one dispenser have lately been among the inmates of the Islington Workhouse. Medical men are not a rich body, though it must be allowed that they generally contrive to make ends meet and to maintain an honest independence. It is possible, however, for a medical man to experience misfortune and to come even to the workhouse. But we have ascertained that in the particular cases under notice there is little to excite the sympathy of the profession. There is plenty of real honest poverty even in the medical profession, and its members feel the hard times more than many think they do. But a bare statement of three doctors in one workhouse is apt to convey a wrong impression.

SIR WILLIAM BARTLETT DALBY.

THE latest addition to the lengthy and still lengthening roll of members of the medical profession who have recently received the honour of knighthood is the name of Mr. Dalby, the well-known aural surgeon. Mr. Dalby was born about the year 1840 (and is consequently still in the prime of life), took his B.A. degree at Cambridge University in 1863, and graduated M.B. in 1866. In 1870 he became a Fellow of the Royal College of Surgeons, having previously in 1867, become a Member of that corporation. He is the author of several works on diseases of the ear, and of many contributions to the pages of the various medical and scientific journals. To non-professional readers Mr. Dalby will perhaps be best known as the able and ardent advocate of the pure oral method of educating the deaf and dumb—i.e., by means of lip-reading and articulation. Several communications from him have appeared in the pages of this journal in support of the revolution which has taken place in the education of the deaf, and the plan propounded by him is now almost universally adopted throughout the United Kingdom. Mr. Dalby, who has had a severe attack of bronchitis has recently been on a voyage to Madeira and back, only returning to England on the 5th inst. We congratulate him on having been selected for the honour which Her Majesty has been pleased to confer upon him.

NECESSITY FOR QUINQUENNIAL CENSUS ENUMERATIONS.

THE Registrar-General's Weekly Return will in 1886, as was the case in the preceding four years, deal with the vital statistics of London and its outer ring, and of twenty-seven of the largest provincial towns. On the hypothesis that this urban population has increased since 1881 at the same rate that prevailed between the last two censuses in 1871 and 1881, the aggregate population dealt with is estimated at ten and a quarter millions in the middle of this year. This signifies that the increase of this population from the middle of last year to the middle of this year, partly by excess of births over deaths and partly by immigration, is estimated, on the above-mentioned hypothesis, at nearly 230,000. It is now, however, nearly five years since the last census enumeration, and the long-continued period of depression which has recently so severely affected many of our commercial and manufacturing districts causes more than a suspicion that the population of our large towns has not during recent years increased at the same rate that prevailed during the last intercensal period. There seemed so strong a ground for this suspicion in the case of some of the towns that returns of inhabited houses on the rate-books have been called for, and a note has been appended to the Weekly Return just issued, being the first for 1886, calling attention to the fact that if the populations of Leicester, Salford, and Bradford have increased since 1881 at a rate not exceeding that of the inhabited houses on the rate-books (instead of the rate of increase of population between 1871 and 1881), the death-rates are understated by about one-fifteenth, one-thirteenth, and one-tenth respectively. On the other hand, the rate in Cardiff is, through a probable under-estimate of population, overstated by about one-eighth. It may reasonably be presumed

Digitized by Google

that doubt prevails, though to a less extent, with regard to the approximate accuracy of the estimates for many of the other towns. Such doubts seriously affect the value of the vital statistics of our large towns, the trustworthiness of which has so direct and important a bearing upon sanitary effort and health progress. These doubts, moreover, cannot be removed until another census enumeration gives a new and trustworthy basis for calculation. Is it useless to urge both upon the Government and upon local authorities the urgent necessity for a quinquennial census, at any rate in all large towns?

OBSTINATE VOMITING CURED BY THE STOMACH-TUBE.

DR. MAERE has communicated to the Ghent Medical Society a case in which a young woman who had had some mental shock suffered from such extreme irritability of the stomach that nothing whatever could be retained. The bowels also absolutely refused to act. This obstinate constipation was overcome by faradaism applied by means of an insulating sound with a metallic button introduced into the rectum. Nourishment was given by the bowel. At last, as the patient's condition appeared to be somewhat critical, Dr. Maere, after painting the pharynx with a 1 per cent. solution of cocaine, introduced a Debove's stomach-tube, and poured in a litre of milk and water in equal proportions. This was retained, and afterwards the patient was able to take and retain gradually increasing quantities of liquid nourishment. In a week she was convalescent. The author suggests that the girl's hysterical condition had caused the stomach to contract in the same way as the limbs sometimes do in these cases, and that when this was once forcibly overcome by feeding through the stomach-tube it did not recur. He remarks that painting the pharynx with cocaine is, as has been pointed out by Dr. De la Roche, much more effectual in facilitating the passage of the œsophageal tube than the application of bromide of potassium.

MESSAGES IN PARISH CASES.

THE servants of medical men, as a rule, are not negligent in delivering messages concerning patients, either private or parochial. But at Southport, at an adjourned inquest on the body of an old woman named Mrs. Jane Wright, it was alleged by some of the witnesses that messages delivered to the servant both on Tuesday and Wednesday were not given to Mr. Moore. Those delivered on Thursday were more successful, and the patient was seen by that gentleman on Friday. The delay led the coroner and jury to reflect both on Mr. Moore and the servant. If there is any difference, as the coroner said, in the importance of messages from paupers and private patients, it is in favour of the poor, for they cannot help themselves by sending for other medical help as private patients can.

"CASES OF URGENCY."

MEDICAL OFFICERS, under the Poor-law system, are far too commonly "censured" or "cautioned" by coroners and their juries for neglect for which they are not responsible. A little more courage is needed, on the part of district officers particularly, to place the question of responsibility in a clear light. If a relieving officer give an "order" for medical relief, it should be his duty and business to mark it in such way that the medical officer may clearly understand whether the case is really an urgent one; and the relieving officer should, moreover, be required to make it clear to the person to whom he gives the order that it is to be delivered immediately. It must not be assumed that medical officers are always waiting on their doorsteps to run at the bidding of the first person who calls them. It is notorious that parish clergymen, Roman Catholic priests, and district medical officers are exposed to the most annoying and injurious hoaxes with regard to the urgency of the cases to which they are called. The not unnatural anxiety of friends very commonly leads to exaggeration of need in their cases; but there is something beyond this—a margin of carelessness and wanton indifference to the time and toil of the official, which ought to be exposed and condemned. It is the universal experience of medical officers in charge of districts throughout the country that, of several apparently equally pressing "calls," there is no sure way of telling which ought to be obeyed first. And when a medical man is censured or cautioned by a coroner, as at Little Missenden a few days ago, insult is added to injury in a way that cannot be too sternly or indignantly reprobated.

THE SPREAD OF INFECTION THROUGH ELEMENTARY SCHOOLS.

WE have received from Mr. S. W. North, medical officer of health to the city of York, a series of papers which show that the Town Council have determined vigorously to aim at the prevention of the spread of infection through the agency of elementary schools. The sanitary authority have delegated their powers under the Education Code to Mr. North, in so far as the exclusion of scholars from specified houses and districts is necessary for the preservation of health, and the co-operation of the managers and school teachers is sought in order to give effect to such prohibition. A number of printed forms have been prepared in order to acquire and impart the information needed with the utmost despatch and with the least difficulty, and it is evident that a considerable attempt will be made to control the spread of infection through school attendance by the less rigid action of exclusion from school, rather than by the complete closure of the schools. For success in the exclusion system, the Town Council and their officers will have the advantage of an immediate notification of infectious disease, but they will still be largely dependent on the goodwill of the managers and teachers. The actual closure of a school is only to be carried out as the result of a special resolution of the urban sanitary authority. It is right that this proceeding should be carefully considered, the more so as it is one against which the school managers have the power of appeal to the Education Department. But when such closure is necessary as the result of the failure of the exclusion system, it has generally to be carried out immediately, and it is to be hoped that the authority will not fail to meet specially on such an emergency, so that there may be no delay in giving effect to the advice of their medical officer of health in this respect.

ANOTHER DISASTER WITH BENZOLINE.

SOME months ago we published an abstract of rules to be observed in the management of lamps containing inflammable oils, and issued with the authority of Sir G. Abel. The precautions then enjoined were amply sufficient to meet almost any emergency. Advice of this kind is most valuable, but it cannot do everything. It may guard against every possibility, yet it cannot prevent accidents. For instance, a few days ago a most serious explosion, attended with loss of life in one case and severe bodily injury in others, occurred, it is supposed, from bringing a can of benzoline used in filling an exhausted lamp in contact with a lighted taper. This is a sad though simple story, especially for the poor old lady who was the unintentional cause of the misfortune, and who herself suffered in a painful degree. Her act, however, is by no means unique. It is a fact that some persons will even charge a lamp with oil while the wick is alight. The marvel therefore

Digitized by Google

is that accidents are not more common. One may cry caution, and describe at length the qualities of explosive oils to little purpose, when the lesson of accidents themselves is not more generally felt. A given example is too apt to be set aside as an isolated one. The danger which it illustrates has been escaped before; it may be encountered again. Such is the argument, if argument it is; and while people will think and act in this way, the list of such accidents is not likely to be kept down.

THE THREE TOWNS FRIENDLY SOCIETIES' MEDICAL INSTITUTION.

OUR readers are aware that we have never approved of those huge co-operative arrangements between Friendly Societies for the purpose of extinguishing medical clubs on a smaller scale. We have always thought them too obviously suggestive of an attempt to beat down remuneration for medical service to such terms as only an inexperienced or impecunious man would be likely to accept, and then only for such a time as his health would hold out or his sense of self-esteem come to assert itself. Such experiments have shown a heartless disposition to exact an enormous amount of work for a mere pittance, and one very objectionable feature of them has been the absence of any efficient test of fitness of cases. In the Three Towns things have been going pretty favourably for the Societies till now, when they have broken with their medical man on the subject of cabs. As the Israelites were expected to make bricks without straw, so the medical officers of the institution were given to understand that they were expected to see innumerable patients with a very inadequate allowance for cab fare. Thereupon Mr. Keiley resolved not to use a cab, but then the members complained that they were not promptly attended to. The Executive Committee, designing further changes unfavourable to the medical men, two of them have resigned. It is exceedingly desirable that these appointments should be declined by medical men who respect themselves and wish for the respect of their professional brethren.

ARRESTED AND CURED PHTHISIS.

DR. DETTWEILER of Falkenstein (Taunus), who has had much experience in the treatment of phthisis at that health-resort, has published a report upon seventy-two cases which have been completely cured within the space of from three to nine years. The returns of the German Collective Investigation Committee appear to have stimulated him to investigate the cases known to him; for in these returns there are fifty-seven cases of cured phthisis contributed by seventeen practitioners. During ten years at Falkenstein there have been 1325 patients in residence; excluding non-phthisical cases and those phthisical who only remained a month under treatment, there remained 1022 cases, which the symptoms, physical signs, and microscopic examination of the sputa proved to be undoubtedly cases of phthisis, the detection of bacilli in the latter cases observed being further confirmatory of the diagnosis. Of this number 132 were described as completely cured, and Dr. Dettweiler was able to learn the subsequent history of ninety-eight of these cases. The replies received to his letters showed that since their residence, eleven had died, mostly from intercurrent disease; twelve had relapsed, but recovered; three remained ill; but in seventy-two there had been no further extension of the disease. He has tabulated these cases, showing the signs presented by them when under his care, their subsequent condition, and the length of time that they have remained ill. The cases included thirty-seven male and thirty-five female patients; in nineteen the disease involved the right lung, in ten the left, and in the remainder both lungs were affected. It is pointed out that in no single instance was the disease transmitted to the non-phthisical residents. The results of his inquiry seem to Dr. Dettweiler to justify the statement that under favourable conditions bacillary phthisis is very amenable to treatment. It would be interesting to get similar inquiries made at other health-resorts; and we may mention that Dr. Vincent Bowditch of Boston records (*Boston Med. and Surg. Journal*, Dec. 10th) a case of well-marked phthisis in a young lady twenty-three years of age, in which numerous bacilli were found in the sputum, but where the disease became entirely arrested by careful hygienic and climatic treatment. Dr. Bowditch thought the case proved that the rapidity of a fatal issue is not always directly proportionate to the number of bacilli, and that the presence of numerous bacilli in the expectoration is not inconsistent with complete arrest of the disease.

UNIVERSITY AND HOSPITALS OF BRUSSELS.

THE University of Brussels is in a ferment—not, we hasten to explain, on account of the Englishmen who attend the examinations for the purpose of obtaining a degree which is denied them at home: the said university has other functions, though we in this country are accustomed to overlook them somewhat. Well, the students have "struck," as a Belgian medical journal informs us, because the Administration des Hospices proposes to dismiss and replace the medical officers of the hospitals, even including the university clinical professors. All sorts of methods are being employed to bring pressure to bear on the sapient Administration to persuade it to rescind its resolution. The students have signed a petition, the councils of the hospitals and of the university have met and protested, and the communal authority has passed resolutions, so that it is to be hoped that something will result from all this storm, if only a great change in the nepotism and favouritism which are said to be rife in the Administrative Commission, which has the function of making the appointments to the medical staffs of the Brussels hospitals.

THE VICTORIA HOSPITAL FOR CASTE AND GOSHA WOMEN.

THE arrangements made for the carrying on of the Victoria Hospital for Caste and Gosha Women, the opening of which in Madras we reported in a recent issue, have provoked much hostile criticism from the native press. The two defects in the plans of the committee upon which the greatest stress is laid, are, first, the extraordinary expenditure for supervision over working expenses; and, secondly, the fact of the rejection of indigenous talent, education, and experience, and the seeking out of India for these qualifications at an expense to which the funds are inadequate. Considering that the hospital has just been opened—opened, too, without a single in- or out-patient calling for its aid,—there is, as yet, the orities contend, hardly any work for the lady superintendent to do in the hospital, and an assistant is at present not needed. Nevertheless, one has been engaged to go out from England. The monthly expenditure is calculated at 1125 rupees, and out of this sum 925 rupees have been reserved as salaries and allowances to the lady-superintendent and the assistant (resident) lady superintendent; in other words, over 82 per cent. of the monthly income—and that income is only assured for a few months—is to be expended on superintendence, and little over 17 per cent. is to be expended on the internal arrangements, matron, nurses, and servants. This seems an extravagant disproportion, and we do not wonder that it has prov'".ed murmurs, both loud and deep, at the financial temerity of the committee in agreeing to such a division of the expenditure. With regard to the second objection, that of the rejection of native talent, we

Digitized by Google

can express no opinion, those on the spot being best qualified to judge of the fitness of the local candidates for the post of assistant lady superintendent. At the present rate of expenditure in the administrative department, it is evident that, unless there is a very great increase in the donations and subscriptions to the hospital, we may expect that more than three-fourths of its expenses will have to be paid by Government, and it will then be, to all intents and purposes, a Government institution. Is that what was meant when the scheme was proposed?

UNVACCINATED COMMUNITIES IN NEW SOUTH WALES.

AN editorial writer in the *Sydney Daily Telegraph* endeavours to use the melancholy epidemic of small-pox in Montreal so as to rouse his fellow-colonists to the risks existing amongst them. Referring to the 100,000 French Canadian Catholics who are unprotected, like our small-pox-loving fellow-subjects at Leicester, and who have supplied the chief victims in the recent epidemic, when sometimes 2500 lay sick in one day, he points out that, perhaps from mere apathy and a false sense of climatic security, there are probably 50,000 unprotected persons in Sydney alone who are providing material for the variolous flames when they are fairly lighted. We cordially endorse the advice of our contemporary to those who are unvaccinated to get well vaccinated, and to those who are well vaccinated to get well revaccinated. To the credit of the Pope, be it said, the French Canadians remain unvaccinated now against the specific advice of his Holiness. Our Australian fellow-subjects do not need the advice of the Pope in this matter, but it is gratifying to see how universally authority for once is on the side of science. Our colonies cannot too soon institute a system of public vaccination; and if their intelligence is not more backward than we take it to be, it will be a compulsory system.

NOISELESS COAL FIRES.

THE sick, and those who watch by their bedsides, know how terribly disturbing is the noise of "putting coals" on the fire, whether they be violently thrown on in the manner generally adopted by servants and nurses (skilled or otherwise), or placed more carefully with the tongs, as kind relatives or friends will *sometimes* "make up the fire" in their sympathy with a sufferer. Even under the most careful manipulation loose pieces of coal are almost sure to fall, and a disturbing rattle is the result. This may appear to be a very small matter to look back upon, but at the time it is by no means unimportant, and in some cases very great distress and even injury may be produced by it. A very simple precaution will suffice to prevent the annoyance altogether. If a few paper bags be supplied to the servant who replenishes the coal-box, and these are filled with pieces of coal, nothing can be easier than to lift one or more of these packages on to the fire noiselessly, and so settle them that when the paper burns the coals may not fall out of the grate. By this obvious method a noiseless coal fire may be secured.

METRITIS IN YOUNG GIRLS.

ACCORDING to Dr. Gallard, of the Hôtel Dieu, young girls who suffer from violent metrorrhagia alternating with profuse purulent discharge, due to metritis, should be treated with cold injections and sitz-baths, combined with ergotin, hamamelis, digitaline, and iron internally; and if these means are not successful, recourse should be had to an intra-uterine injection of perchloride of iron, care being taken to use a graduated syringe and an intra-uterine tube whose calibre is decidedly smaller than that of the cervical canal.

TEMPERANCE DRINKS.

AT the Birmingham Police-court, on the 8th inst., summonses were taken out by the Inland Revenue against a shopkeeper for selling, and against a firm of manufacturers for supplying, certain drinks, under the name of temperance wines, which were alleged to be intoxicating. An analyst to Somerset House gave evidence that the port wine was a fermented liquid containing 17·4 per cent. of proof spirit; the sherry was a liquid of the same description, and contained 19·6 per cent. of proof spirit: thus showing that a large proportion of alcohol was hidden under the seductive title with which the bottles were labelled. Another compound of a similar kind was sold under the name of "hot Tom," the purpose of which was to give a spiced flavour when added to beer. It was suggested for the defence that fermentation must have occurred after the wines had been bottled; but the absence of carbonic acid in any quantity proved that this could not have been so. The salesman was fined 1*s.* and costs, the manufacturers £10—a penalty which will probably stop the sale of this particular form of refreshment, but which will be of more service in calling the attention of teetotallers to the nature of the trade in powerful stimulants sold under tempting and unsuspecting names.

ATROPHODERMA PIGMENTOSUM.

THE pathology of this affection, which has received so many names, appears to be fairly understood as the result of the labours of Kaposi, Neisser, Vidal, Radcliffe Crocker, and others. About thirty-six cases appear to have been placed on record. Dr. White of Harvard University describes two cases in the *Journal of Cutaneous and Venereal Diseases*. The cases occurred in a family of Russian Polish Jews. There were seven children in the family, and the two affected were the second and sixth. The first case was a boy aged seventeen, in whom the melanotic and atrophic conditions were well marked, and telangiectasis was evident only about the face. The second case was also a boy, three years old, in whom the only marked morbid condition appeared to be on the face, and to consist of abnormal pigmentation. The author avers that there can be no doubt of the correctness of the diagnosis in the cases, the first of which exhibits everything characteristic of the disease, except the final transformation of parts into malignant growths. White regards the melanosis as the initial lesion, and would so name the disease, adding the terms telangiectodes and atrophica as secondary conditions. Radcliffe Crocker says the disease is admittedly an atrophy of the skin, and suggests the term "atrophoderma pigmentosum."

VENESECTION FOR HÆMORRHAGE.

A CORRESPONDENT of a Madrid medical journal, writing from Zaragosa, says that in cases of hæmorrhages, notably in hæmoptysis and in epistaxis, if astringent remedies fail to arrest the attack, the simplest and best proceeding is to open the saphena or basilic vein. So far from alarming the patient and his friends, he finds that it rather tends to reassure them, for there is an idea very prevalent in Spanish towns that "a doctor who does not bleed is not a good one." Many patients, too, with epistaxis will exclaim that they would rather die than allow an instrument to be passed into the nostril, but they will readily consent to allow a vein to be opened, especially when they are assured that this proceeding will almost infallibly cause the flow of blood from the nose to cease. The writer says that this assurance may be given with the utmost confidence, as he has constantly employed venesection for this purpose with very great success.

Digitized by Google

PUBLIC HEALTH IN MINNESOTA.

AN official publication entitled *Public Health in Minnesota* has been established by the State Board of Health as a means of communication between that board and health officers. It is published monthly, and besides containing the suggestions, regulations, and orders of the State Board, news as to sanitary work and discoveries abroad, laboratory and meteorological notes, and book notices are included in the information it contains. Some of the numbers refer to the results of sanitary inspections, others to the recent prevalence of small-pox and the means necessary to its prevention. Again, the state of our knowledge with respect to the influence of bacteria in the production of diseases such as cholera, and contributions relating to many current sanitary discussions, are grouped with items of local news, which it is important to convey to health officers. It is evident that such a pamphlet must be of considerable value in effecting the object which its originators have held in view.

SEVERE CASE OF MORPHIA-POISONING.

DR. YAVORSKI gives in the *Vrach* an account of a case of poisoning by morphia, in which a woman had taken about thirty grains of the acetate in powder, and, as it did not act quickly enough to please her, had followed it up with half an ounce of tincture of opium. She slept a few hours, and then awoke, complaining of being very ill; she did not vomit. Dr. Yavorski saw her about an hour later. He injected apomorphia, and in a quarter of an hour this produced vomiting, after which strong coffee was given and vomiting again induced by apomorphia. Atropine was then injected in doses of one-sixth and one-twelfth of a grain every fifteen to thirty minutes, till in ten hours more than two grains of atropine had been given. Tincture of musk was also injected—120 minims altogether. The patient recovered.

CHOLERA IN PALERMO.

Il Morgagni for December publishes a report of researches conducted on the recent cholera epidemic in Palermo by Professor Lepidi-Chioti, assisted by Dr. de Simone. The results were entirely confirmatory of Koch's, on the comma bacillus as the cause of cholera.

A CONTRIBUTOR to the *Newcastle Weekly Chronicle*, in the most recent of a series of articles on "Our Young Ladies, by One of Them," calls the attention of her readers in plain and forcible terms to the dangers attending the use of hair dyes, the consumption of arsenic, tight lacing, cumbersome clothing, and low dresses. It is gratifying to find one of the female sex condemning the use of all such meretricious aids to what is supposed to be beauty; but we fear the day is far distant when all her sisters will be of the same mind. We hope, however, that the writer of the article alluded to does not forget the proverb which tells us that "an ounce of practice is worth a pound of theory."

A FIRM of druggists in Jersey have been fined for importing Vin Mariani, a medicinal wine containing a good percentage of alcohol, without having made a declaration on the subject to the Excise authorities. By the insular law all spirituous liquors, for whatever purpose used, must be declared, but it is hard to believe that such a provision was intended to apply to a case like the one under notice.

THE Gresham Medical Lectures, the subject of which this year will be the Treatment of Disease, will be delivered on January 19th, 20th, 21st, and 22nd, 1886, by Dr. E. Symes Thompson, at Gresham College, Basinghall-street, E.C.

ON the 8th inst. a party of high officials visited the Toorah Convict Prison, Cairo, at the invitation of Dr. Crookshank, the Director-General. Some few of the visitors remembered the state of these prisons prior to Dr. Crookshank's administration, and congratulated him heartily on the general improvement and perfect order prevailing in the establishment. The good work done in this department has hitherto been little recognised, and it is pleasing to be able to point to at least one reform which has been thoroughly well carried out under English superintendence.

AT the annual meeting of the Allotments and Small Holdings Association held at the Westminster Palace Hotel on Monday last, Mr. J. B. Clark, L.R.C.P., M.P. for Caithnessshire, stated that, from his experience of rural practice, want of milk caused the illness of two-thirds of the children brought under the notice of the doctor, and that "three acres and a cow" would do more than anything else to promote the health and happiness of the people generally.

THE authorities at Montreal are making great efforts to check the small-pox epidemic in that city. According to latest advices a law has been enacted by the Provincial Board of Health, and confirmed by the Governor in Council, making it a crime punishable by a fine of twenty dollars or imprisonment in the common gaol "to advise others to refuse vaccination." This enactment will doubtless go far to check the efforts of the anti-vaccinationists.

DR. DYKE, medical officer of health for Merthyr Tydvil, has reported to his board on underground dwellings—places in which diseases are invariably most prevalent and most fatal. It is to be hoped that the result of his report will be the closure, as human habitations, of all such dens in the town under his care.

THE Russian Government has issued an order that the practice of massage is only to be allowed to be conducted by those who have obtained a licence after examination in the same way as those who practise medical gymnastics are licensed, and massage must always be carried on under the orders and supervision of a medical man.

A COLLECTION of the songs and verses by members of the well-known medical clubs in Edinburgh, many of which are familiar to the outside public as well as the medical profession, is about to be published by Messrs. Maclachlan and Stewart.

THE meetings of the Sanitary Congress will most probably be held in Bolton this year. If this be so, it will be an honour to the town, which was the first to adopt the compulsory clauses in reference to sanitary subjects.

AN epidemic of measles is reported to have been for some time prevailing at Luton, Beds, and neighbouring villages, and to have assumed so severe a form as to necessitate the closing of schools at Sundon and Barton.

DR. HIRSCHMANN has been appointed Professor of Ophthalmology in the University of Kharkoff, and Dr. W. Dobronravoff has been elected to the chair of Midwifery and Gynæcology in the University of Kieff.

DR. MORITZ, the senior medical officer of the Obukhoff Hospital in St. Petersburg, being about to resign his post, his colleagues have arranged to hold a farewell dinner in his honour at the Grand Hotel.

Digitized by Google

DR. ANDREW WILSON, F.R.S.E., &c., Examiner, Faculty of Medicine, University of Glasgow, has been appointed an Examiner in Botany in connexion with the Intermediate Board of Education for Ireland.

THE pauper lunacy charges for England for 1885-6 amount to £478,500, being an increase on the previous year of £17,500; for Scotland £84,500, an increase of £500; and for Ireland £98,200, an increase of £2810.

AN examination of candidates for commissions to fill sixteen vacancies in the Medical Department of the Royal Navy will be held at the University of London on Feb. 8th and following days.

THE death is announced in St. Petersburg of Dr. Hirschfeld, editor of the medical journal *Prakticheskaya Meditsina*, and translator of many foreign medical works into Russian.

M. PAUL BERT has been appointed by the French Government Resident in Annam, Tonquin, and Gambodia, and is to embark for Hué on the 3rd prox.

SURGEON HEATH, British Army Medical Department, has been killed in action in Burmah. The fatal wound was received whilst he was endeavouring to remove to a place of safety an injured comrade.

SIR J. FAYRER, F.R.S., has been appointed a Corresponding Member of the Academy of Medicine of Paris.

Pharmacology and Therapeutics.

POROUS BELLADONNA PLASTER (A. DE ST. DALMAS, LEICESTER).

THIS is a porous belladonna plaster spread on scarlet felt. Our experience of its use extends over several months, and we have no hesitation in saying that we believe it to be one of the best belladonna plasters ever made. It is very active, is not irritating, and gives plenty of support.

MESSRS. HOWARD AND SONS' CINCHONA PREPARATIONS.

Messrs. Howard and Sons are so well known as makers of cinchona preparations, that very little more is necessary than to call attention to their fluid extract of cinchona from calisaya bark, their fluid extract from red bark, and to the extractum cinchonæ liquidum of the New British Pharmacopœia. Their preparations leave nothing to be desired, and are a credit to British pharmacy.

TASTELESS, ODOURLESS COD-LIVER OIL.

We have received from Mr. W. G. Radley, of Newton Abbot, Devon, specimens of "tasteless, odourless" cod-liver oil and castor oil. We are not quite prepared to say that they are destitute of all taste and odour, and they certainly require a great deal of shaking; but they are fairly palatable, and there can be no doubt that they will be taken by children without difficulty. We hope at some future time to give the cod-liver oil preparation a more extended trial.

PARALDEHYDE.

Dr. Dujardin-Beaumetz, in a recent article on the "New Hypnotics," speaks highly of paraldehyde as a therapeutic agent. He usually prescribes three drachms in six ounces of water, and orders a teaspoonful to be taken in rum, whisky, or kirsh at bedtime. The drug has a peculiar and characteristic odour, resembling the smell of a tippler's breath, and it is only by mixing it with spirit in some form that this can be effectually disguised. Yvon accomplishes the same object by administering it in conjunction with camphor-water, tincture of vanilla, and syrup of virgian prune. As an enema it is greatly superior to chloral, frequently affording a good night's rest after the failure of many other remedies. It does not readily lose its remedial power, and its administration may be continued for a very long time without producing any inconvenience. Dr. Dujardin-Beaumetz thinks that it is especially indicated in strychnia-poisoning, and speaks well of it in the treatment of eclampsia.

PURE TEREBENE.

Pure terebene, prepared by the action of sulphuric acid on turpentine, is a clear, colourless fluid, having the odour of freshly sawn pine-wood. It has recently been introduced as a remedy for chronic bronchitis and winter cough, and is said to be most efficacious in the treatment of the flatulence of dyspeptics. It is usually given in ten-drop doses on sugar every three hours, but as it has no poisonous action the dose need not be very accurately measured. It is agreeable to take, and is preferable in every way to the turpine-hydrate recommended by M. Germain Sée and other observers as a remedy for certain forms of consumption. It is not to be confounded with the terebene employed in surgical practice and in the preparation of soaps. There is reason to believe that it will prove valuable not only in chest diseases but in many affections of the throat and vocal organs.

PICHI, A CHILIAN DRUG.

An account is given in the *Independencia Medica* of a Chilian coniferous plant, the Fabiana Imbricata of Ruiz and Pavón, but called by the natives Pichi. It has, according to them, great powers of controlling almost all diseases of the urinary organs, and is even considered to be capable of causing calculi to dissolve. A study has recently been made both of its chemical and therapeutic properties. It has been found to contain an aromatic essential oil, a resin, and a crystalline substance of a highly fluorescent appearance, which is soluble in ether and in alcohol at 80° C., and very slightly in cold water, but sufficiently so to produce a solution which appears of a magnificent blue colour when seen by transmitted light, but is yellow when seen by reflected light. The therapeutic action of pichi is most marked in cases of vesical catarrh caused by uric acid diathesis, gravel or calculi. Here it diminishes the secretion and allays the irritability of the mucous membrane, thus allowing the gravel a better opportunity of passing with the urine. It has also a diuretic action, which has been found valuable in many cases of icterus, dropsy, and dyspepsia due to the deficient action of the liver. In these cases the preparation employed was the essential oil, which, being absorbed and taken into the circulation, acted as a stimulant of the secretory organs in general. The specific action of the drug, however, is evidently exercised on the urinary apparatus. The writer of the paper from which we quote prefers to use a fluid extract of the plant, of which he gives from two to three ounces daily, dissolved in water, either hot or cold.

ANTIPYRIN AS A HÆMOSTATIC.

Antipyrin, which has been largely used in the treatment of fever for reducing temperature, has proved valuable in the hands of an Italian surgeon, Dr. Casati, as a local hæmostatic. In a case of epistaxis it was employed as a 5 per cent. solution; also, after an operation, hæmorrhage was arrested in three minutes by the application of a 4 per cent. solution of antipyrin. Dr. Casati considers antipyrin preferable to perchloride of iron or the actual cautery for arresting hæmorrhage, because it leaves the wound quite clean, and without any eschar. It has, too, the advantage over ergotine of being non-poisonous, even in large doses, and its antipyretic and antiseptic properties are themselves in many cases of considerable advantage.

PELLETERIN.

Tauret in 1878 isolated an alkaloid out of the pomegranate bark. Schröder has studied the physiological action of pelleterin on frogs and rabbits. It increases the reflex irritability of the spinal cord and disturbs locomotion, probably as the result of its action on the cerebellum. It raises blood-pressure by acting on the vaso-motor centre and paralyses the vagus. In man, giddiness, disturbance of sight, feeling of weakness in the legs, and occasionally nausea, vomiting, cramps, and convulsions were the phenomena observed. Pelleterin kills the tapeworm of cats, and it has proved successful in that of man, but its high price precludes its general use.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6239 births and 3927 deaths were registered during the week ending January 9th, being the first week of 1886. The annual death-rate in these towns, which had been 23·0, 19·3, and 25·3 per 1000 in the preceding three weeks, declined again last week to 22·5. During the thirteen weeks of last quarter the death-rate in these towns averaged 20·0 per 1000, and was 2·6 below the mean rate in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 18·5 in Sheffield, 18·8 in Newcastle-upon-Tyne, and 18·9 in Wolverhampton. The rates in the other towns ranged upwards to 27·8 in Nottingham, 28·3 in Huddersfield, 28·5 in Manchester, and 30·8 in Bolton. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 395 and 497 in the previous two weeks, declined again last week to 448; they included 174 from whooping-cough, 113 from measles, 42 from "fever" (principally enteric), 41 from diarrhœa, 38 from scarlet fever, 37 from diphtheria, and 3 from small-pox. No death from any of these zymotic diseases was recorded last week in Halifax, whereas they caused the highest death-rates in Salford, Bolton, and Plymouth. The greatest mortality from whooping-cough occurred in Sheffield, Cardiff, and Bolton; from measles in Oldham, Nottingham, and Plymouth; from scarlet fever in Leicester, Huddersfield, and Bradford; and from "fever" in Oldham and Norwich. The 37 deaths from diphtheria included 21 in London, 4 in Liverpool, and 2 in Bristol. Small-pox caused no deaths among the residents of London and its outer ring, and but 3 in the twenty-seven provincial towns, of which 2 occurred in Liverpool and 1 in Nottingham. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding eight weeks from 90 to 41, had further fallen to 35 on Saturday last, only one case having been admitted to these hospitals during the week. The Highgate Small-pox Hospital contained 6 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 383 and 610 in the preceding two weeks, declined again last week to 518, but were 25 above the corrected average. The causes of 86, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Portsmouth, Brighton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Halifax, Salford, and Leicester.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·1, 22·9, and 21·6 in the preceding three weeks, rose again to 22·9 in the week ending Jan. 9th, and exceeded by 0·4 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 15·5 in Leith and 16·1 in Edinburgh, to 27·8 in Perth and 28·7 in Glasgow. The 565 deaths in the eight towns showed an increase of 37 upon the number in the previous week, and included 15 which were referred to whooping-cough, 10 to diarrhœa, 8 to scarlet fever, 6 to diphtheria, 5 to "fever" (typhus, enteric, or simple), 1 to measles, and not one to small-pox; in all, 45 deaths resulted from these principal zymotic diseases, against numbers declining steadily from 56 to 32 in the preceding four weeks. These 45 deaths were equal to an annual rate of 1·8 per 1000, which was 0·8 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 7, 12, and 13 in the preceding three weeks, further rose last week to 15, of which 12 occurred in Glasgow. The 10 deaths attributed to diarrhœa also exceeded the numbers in recent weeks, and included 6 in Glasgow. The deaths from scarlet fever exceeded the number in the previous week by 5, and included 4 in Aberdeen and 2 in Glasgow. Four of the 6 deaths referred to diphtheria and 4 of the 5 to "fever" were returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined from 178 to 143 in the preceding four weeks, further fell last week to 132, and were 66 below the number returned in the corresponding week of last year. The causes of 80, or more than 14 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 34·4, 22·8, and 37·1 per 1000 in the preceding three weeks, declined again to 28·8 in the week ending January 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 27·0 per 1000; the mean rate during the same period did not exceed 19·5 in London and 19·0 in Edinburgh. The 195 deaths in Dublin last week showed a decline of 56 from the high number in the previous week, and included 15 which were referred to the principal zymotic diseases, against 28, 16, and 32 in the preceding three weeks; 8 resulted from whooping-cough, 3 from scarlet fever, 3 from "fever" (typhus, enteric, or simple), 1 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 15 deaths were equal to an annual rate of 2·2 per 1000, the rate from the same diseases last week being 2·9 in London and 0·6 in Edinburgh. The fatal cases of whooping-cough, which had been 15, 10, and 17 in the previous three weeks, declined again last week to 8. The 3 deaths from scarlet fever exceeded the numbers in either of the previous two weeks; while the 3 deaths referred to "fever" showed a decline from recent weekly numbers. Three inquest cases and 6 deaths from violence were registered; and 63, or nearly a third, of the deaths were recorded in public institutions. The deaths of infants showed a marked decline from the numbers in recent weeks. The causes of 21, or nearly 11 per cent., of the deaths registered during the week were not certified.

VITAL STATISTICS FOR KENSINGTON.

Dr. Dudfield's last monthly report on the sanitary condition of Kensington gives a summary of the vital statistics for 1885. On an estimated population of 172,000, the birth-rate, which is low compared with that for London generally, was only 23·4 per 1000, or 5 below the decennial average, and the death-rate was 16·1 per 1000, or 1·5 below the decennial average, and 3·5 below that of the metropolis as a whole. The deaths amongst children under one year of age were somewhat numerous, amounting as they did to a rate of 16·1 per cent. of the registered births. The deaths classed as zymotic were 361 in number, and amounted to a rate of 2·1 per 1000, this being slightly below the decennial average and considerably below that for the whole of London, where the rate reached 2·8. These deaths included 25 from small-pox, 22 of them occurring in the hospitals of the Asylums Board; there were also 111 deaths from measles which led to an increase in the infant mortality.

THE SERVICES.

GREENWICH HOSPITAL PENSION.

THE Lords Commissioners of the Admiralty have awarded the Greenwich Hospital pension of £50 a year for fleet surgeons and staff surgeons, rendered vacant by the death of Staff Surgeon James K. Ballard, to Deputy Inspector-General James G. T. Forbes.

Surgeon-Major Galbraith, serving with the Egyptian army, having completed duty with the Recruiting Commission, has been attached to the head-quarters staff of that force for special service.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Arthur Charles Gaye to be Brigade Surgeon, vice Frederick William Moore, granted retired pay. Surgeon-Major John Alexander Scott to be Brigade Surgeon, vice Austin Jonas Ferguson, granted retired pay.

ADMIRALTY.—The following appointments have been made:—Surgeon Ernest D. Minter, to the *Lion*, additional, for disposal; and Surgeon Thomas E. H. Williams, to the *Terror*.

THE HONOURABLE ARTILLERY COMPANY OF LONDON:—Surgeon Thomas Stevens Barringer retires into the Veteran Company, with the honorary rank of Surgeon-Major, and has permission to wear his uniform on retirement; Walter Culver James, Gent., M.D., to be Surgeon, vice Barringer, retired.

Digitized by Google

ENGINEER VOLUNTEERS: —1st Newcastle-on-Tyne and Durham: Charles Nairne Lee, Gent., M.B., to be Acting Surgeon.

RIFLE VOLUNTEERS. — 3rd (the Buchan) Volunteer Battalion, the Gordon Highlanders: Acting Surgeon George S. D. Knowles resigns his appointment.—4th Volunteer Battalion, the South Wales Borderers: Surgeon Robert Smyth is granted the honorary rank of Surgeon-Major.—4th Volunteer Battalion, the Norfolk Regiment: Acting Surgeon Thomas Harry Bate Rodwell resigns his appointment.

"Audi alteram partem."

THE SUPRAPUBIC OPERATION.

To the Editor of THE LANCET.

SIR,—Mr. Hodgson Wright appears to me to have misapprehended the essential feature of the new form of suprapubic operation by which it is proposed to replace the old one. The "well-bent sound" or staff is that which hitherto we have all used. He will find it in my own or in any other work which describes the operation. The new proceeding has for its object to remove the peritoneum from its natural vicinity to the pubis, and leave a large interval for the incisions; while the bladder becomes an abdominal organ instead of a pelvic one. In this way the danger of injury to the peritoneum, the chief danger of the high operation, as heretofore performed on a staff, is removed. This object is attained by injecting the rectum and the bladder, and the staff then becomes unnecessary, while its presence is incompatible with the moderately distended condition of the bladder. The effect of distension on the rectum, which is the chief factor in placing the peritoneum out of harm's way, can be best appreciated by drawings from the subject demonstrating the condition. These are fully shown, with a far more complete statement of the whole question, in a little work on the Suprapubic Operation, which will appear next week, by

Yours obediently,

Wimpole-street, Jan. 12th, 1886. HENRY THOMPSON.

THE QUESTION OF A NEW UNIVERSITY FOR LONDON.

To the Editor of THE LANCET.

SIR,—At the meeting of Convocation of the University of London, fixed for Tuesday next, Jan. 19th, it is very probable that important subjects for discussion will be brought forward, and I ask you to permit me not only to remind my fellow medical graduates of the importance of duly considering the dangers of the situation, but also to put fairly before all those who are interested in the higher medical and general education my view of the existing wrongs and the proposed remedies.

I cannot help thinking that with graduates in the various faculties of the University the field of debate is far from clear; that one section does not thoroughly comprehend the views of another section; that what to one group seems to be an adequate remedy for existing evils, to another is no remedy at all. Since the collapse of Lord Justice Fry's scheme for a complete reorganisation of the University a much more moderate plan has been formulated. There seems to me little cause for objection and not a little of valuable suggestion for reform in the proposals of Mr. Magnus (*vide* THE LANCET of December 5th, 1885, p. 1090). They are chiefly directed to the providing a means whereby the views of teachers in the various faculties may be adequately presented to the Senate, and to a partial reconstruction of the Senate, so that teachers may have a more direct representation therein. It may be urged by some that the teachers, even with the very best motives, must have some tendency to make matters easier for those whom they teach, and that there may result a lowering of the standard in examinations for degrees; but most will probably agree that this is a remote danger in the [illegible] plan of Mr. Magnus, and that certainly the voice of the teachers ought to be heard. This is not the danger. The point is, that in all these schemes for reorganising the University, which are considered in Convocation of the University the fringe of the question which is agitating aspirants for degrees outside, is not even touched. Even in the discussion on Lord Justice Fry's propositions it was urged and reiterated that the standard for degrees should not be lowered. How, then, will those be helped who clamour (and that most justly) for the degree of Doctor of Medicine for the student in London who shall manifest the same aptitude and diligence that would obtain for him such a degree in any other of the universities of the United Kingdom? The list of those successful at the late examination for M.D. Lond. contained twenty-seven names, and it was, I believe, an exceptionally long one. Twenty-seven M.D.'s in one year from all those who have struggled at the matriculation examination! There is no escape from the dilemma: either the standard for examinations must be very much reduced, and therefore the degrees in the London University must be proportionately depreciated in value—a course which the authorities have deliberately pronounced against,—or the University must lie open to the imputation of shelving the most important question that public opinion submits to it.

Granted that London wants facilities for conferring ordinary degrees, is it necessary to level down the University of London in order to supply this want? I have already argued this question in the negative sense. As at present constituted the London is an Honours University—not as regards medicine only, but in all faculties. Its originators deliberately framed its regulations so that it should differ from all existing universities, and should be an indirect means of elevating the standard of education throughout Great Britain and her colonies. In the opinion of many, and certainly in that of myself, the plan was a wise one, and has borne the fruits of success. It cannot be denied, however, that those who from force of circumstances cannot comply with its stringent regulations and cannot get over the difficulties of its examinations, and yet would be the gainers of a degree if they happened to be members of other universities, have a distinct grievance. I would urge as the best and simplest plan of overcoming the present difficulties that the University of London should remain, just as at present, an Honours University, its mechanism with all reasonable improvements preserved, but the severity of its tests in nowise reduced, and that another university, which might be called the University of Westminster, should be founded to confer ordinary degrees. By ordinary degrees I mean degrees which are conferred after examinations which present no greater difficulties than those of the other universities of the United Kingdom. It is, I suppose, conceded that a student who goes to Oxford or Cambridge and manifests reasonable aptitude and diligence is fairly sure of obtaining his degree at the close of his curriculum. Not so with a student who hopes for a degree in the London University. It is well known that many run, but few win. In this case it is as if at Cambridge the examiners for the B.A. degree in the Mathematical Tripos stopped after the list of Wranglers and senior optimes, decreeing that all those now classed as junior optimes and pollmen (those worthy of an ordinary degree) had failed.

The question that the University of London should be asked is, Is it willing to work in lines parallel with those of another university, such as that I have mentioned? Would it be so very difficult to arrange that the one should be the honours branch of the other? Then none of the existing mechanism would be destroyed, the present degrees, the value of which is recognised, would not be depreciated, and their now intelligible connotation would be preserved. The Association for Promoting a Teaching University would surely be more likely to succeed if its initial work were one of construction and not destruction, and many good educational institutions would crystallise round the new University if it had the power of granting degrees after a fair but not an excessively difficult examination.

With such a scheme the project of the Royal Colleges of Physicians and Surgeons to give to those who have passed the examinations for their licences facilities for proceeding to the degree of M.D. would best harmonise. The Royal Colleges would constitute, without any necessary change, the Medical Faculty of the new University. It would be surely an advantage to them that they should not be isolated, but associated with other faculties of arts and sciences. Such an association would probably promote the success of their

Digitized by Google

scheme, for though the application for power to confer degrees merely in medicine might provoke the active, and perhaps successful, hostility of medical corporations with vested interests, it would be difficult to withstand a great movement tending to promote the higher education of large numbers of the population.

I am, Sir, yours faithfully,

Harley-street, Jan. 11th, 1886. A. ERNEST SANSOM.

THE RELATION OF THE PAROTID TO THE GENERATIVE ORGANS.

To the Editor of THE LANCET.

SIR,—The interesting letter of Mr. Paget, published in your last issue, has raised a question which I think has not yet received the attention it deserves—viz., Is the parotid in any way related to the generative organs? As writers, and among them Professor Möricke, often commence by taking for granted "the well-known relation which exists between the parotid and the testicle," I think, before we go any further into the matter, we ought to inquire into the facts upon which this doctrine is founded. I suppose the belief was first formed by observing the phenomena of mumps. Now, what do we know of mumps? That although for the most part a disease of childhood, it not unfrequently attacks adults, both male and female. In children the sexual organs are imperfectly developed, and do not suffer. Adult females, as all the books tell us, are liable when attacked to suffer from a "metastasis" affecting the breasts and ovaries, but as after some experience I have never seen a case myself, nor apparently has Professor Möricke, I gather that this complication is comparatively rare. With adult males, however, the case is different; among them a considerable proportion, in my own cases a considerable majority, of the patients suffer from orchitis. This orchitis, it seems to me, may be explained on the one hand by supposing that some relation exists between the parotid and the testicle, or, on the other, by considering it simply as one of the phenomena peculiar to the disease. Now, if the cause is to be found in some relation existing between these two organs, should we not be led to expect, at any rate, some slight manifestation of its influence when the parotid becomes affected by causes other than mumps? As far as I know, however, this is not the case. Again, supposing this mutual influence to be capable of exerting itself in the opposite direction, should we not expect to find the parotid affected far and away more frequently in cases in which the testicle is involved than in any other? Is this the case? Taking the other alternative, may we not consider mumps as an acute specific disease, which has its own selective peculiarities, just as other specific diseases—such as scarlatina and diphtheria—have theirs? This view is, I think, strengthened by considering the period when the "metastasis" occurs. Sometimes the testicle becomes involved whilst the parotid is still affected, more generally when it is recovering, while occasionally there is an interval without local affection, during which the constitutional symptoms are sometimes unusually severe. Surely we should hardly expect the disease to stay thus hovering, as it were, about the system, if it were sent to the testicle through the dominating influence which the parotid holds over it.

We have now to look at the question from the opposite point of view—viz., when the parotid becomes affected secondarily. Attention has been drawn to this side of the question by the fact that a certain, but I venture to think very small, percentage of operations upon the female genital organs have been followed by inflammation of the parotids. I am indebted to Mr. Paget's letter for the means of referring to most of the cases to which I shall allude. Professor Möricke had five cases, four of which suppurated, all after ovariotomy; the mortality is not given. Dr. Goddell's paper elicited in all fifteen cases, all but one of which related to the female genital organs, nearly half of which died. Other cases are given which cannot be catalogued from want of sufficient particulars; but, put together, they show frequent suppuration and a high mortality.

So far as I am aware, three explanations have been offered for these cases. 1. That some were cases of mumps occurring accidentally. 2. That they were due to the operation, which, I suppose, means that they were due to a relationship existing between the parotid and the parts operated upon. 3 That they were septic. Of these the first may be true; the third is certainly true of some of the cases; but it is with the second which we have specially to deal. Now, if it is due to the relationship existing between the parotid and the parts operated upon, what are those parts? Professor Möricke had five cases following 200 ovariotomies, and none after any other operation. He argues that from "the well-known relation existing between the testicle and the parotid we may infer that the same exists between the ovary and the parotid, but he does not explain why four out of five of his cases suppurated. That the the theory of an exclusive relation between the ovary and the parotid was untenable was soon shown by the fact that these cases occurred after other operations involving the peritoneum, such as hysterectomy (Baker), gastrostomy and penetrating wound of the abdomen (Mann). The first line of defence failing, the idea has been proposed that some relation exists between the parotid and the peritoneum. How far this position can be maintained is shown by the fact that cases have occurred where the membrane has not been involved; for instance, after excision of the cervix uteri (Goodall), laceration of the cervix (Emmett), vesico-vaginal fistula (Emmett), and, lastly, lithotomy and circumcision (Stephen Paget). This list does not include the cases occurring on the medical side, notably in typhus, where no special organ can be said to be primarily involved.

Lastly, it seems to me that we are driven by the process of exclusion to the third or septic theory. If we look at the frequent suppuration and the very high mortality of these cases, coupled with the fact that the septic character of many of them was undoubted, I think it is to this cause that we have to look for the true explanation. Are we justified always in saying that the inflammation is not septic because suppuration does not occur? Given a small dose of poison, coupled with a high power of resistance, may not resolution and recovery occur? I do not wish to enlarge upon this part of the question; my position is rather that the evidence of the connexion between the parotid and the genital organs is entirely based upon the phenomena of mumps, which I hold does not justify such a conclusion, and the relation between the female genital organs and the parotid rests upon no good evidence whatever.

I am, Sir, yours truly.

St. John's, S.E., January, 1886. F. T. TAYLER, M.B., B.A.

"THE REAL CAUSE OF HOSPITAL DISTRESS."

To the Editor of THE LANCET.

SIR,—I have read Mr. M'Donagh's letter in your issue of the 9th on "The Real Cause of Hospital Distress and the Only Means of Cure," and I think that it should not be allowed to pass without a brief statement of the case from the hospital point of view. In the first place, I cannot agree with Mr. M'Donagh in thinking that he has put his finger on the real cause of the acknowledged hospital distress, much less on the only cure. I have also to find fault with the letter because of its vagueness. Mr. M'Donagh makes sweeping statements, but he does not back them up with specific instances of the alleged abuse. Moreover, it is a dangerous thing to impute motives in the wholesale way Mr. M'Donagh does, and he seems to me to class all hospitals together, and to condemn all equally—the large general hospital and the small special hospital alike. And while I might be willing to admit that there may be some cause for complaint on the part of general practitioners against special hospitals, I am not prepared to admit that there is the same, or indeed any, valid ground for grumbling at the general hospitals. Patients are inclined to flock to a special hospital, believing that there they get the advice of a medical man who has made their particular ailment his special study, and that he is therefore in a position to know more about it. This does not so strongly apply to general hospitals, and, moreover, there is now, in at least some of our largest hospitals, a most careful system of supervision of out-patients, to the exclusion of unsuitable cases. This is so at the London Hospital, and I believe at several others. At my own hospital, where I saw out-patients for a number of years, I came to the conclusion, after careful study of the matter, that very few of the patients presenting themselves for advice were in a position to pay the fees of any medical man, however moderate these might be. Those who had been ill for any length of time had previously been under

Digitized by Google

the care of some local practitioner, and had paid his fees until loss of work or some other accident rendered them unable longer to do so. Then, and not till then, they came to the hospital. In other cases, I am sorry to say, they came because they could not go on paying, and were none the better for the advice they had got—probably, I should think, because the doctor they had consulted had adopted some such wholesale plan of seeing cheap patients as the one advocated by Mr. M'Donagh, and for that reason had been unable to do justice to his patients. I have already said that I think Mr. M'Donagh is too sweeping in his statements, and especially do I deprecate the way in which he attributes motives of purely selfish interest to those of his brethren who happen to be attached to hospitals. For myself, I believe that most physicians and surgeons see their patients at hospitals faithfully, and do their best for them, without a thought of any direct advantage therefrom, and without thinking of numbers so long as they are not so few as to interfere with clinical instruction, or so many as to overtax their energies. As a matter of fact, is out-patient work directly or indirectly very much of a stepping-stone to practice? I think decidedly not, as Mr. M'Donagh puts it.

I believe the distress of hospitals arises in the main from two causes: (1) The depression of trade, which acts doubly on them by increasing the numbers who seek medical charity and by diminishing the means of those who support hospitals; (2) from the greatly increased number of special hospitals.—I am, Sir, your obedient servant,

Jan. 12th, 1886. PHYSICIAN TO A GENERAL HOSPITAL.

"ARTHRECTOMY."

To the Editor of THE LANCET.

SIR,—In answer to Mr. Wright's letter in THE LANCET of January 2nd concerning a remark of mine at the December meeting of the Leeds and West Riding Medico-Chirurgical Society, I would say that the case of arthrectomy or erasion reported by my friend Mr. McGill healed by first intention, and was so well at the end of four months that the boy walked several miles and had a fair amount of movement in the joint. In the discussion which followed I remarked "that such a perfect result could not often be looked for after erasion, since, out of sixteen cases reported by Mr. Wright, only one similar success had been obtained." In the epitomised report of the meeting it is stated that erasion had only succeeded once in Mr. Wright's sixteen cases; it should have been that such a perfect result had only occurred once. I have Mr. Wright's original paper before me, and extract from it the following results of his sixteen arthrectomies:—"Case 1. Quite well, with movable joint. 2. At end of two years wearing an apparatus because of tendency to displacement. 3. Excision. 4. Amputation. 5. Death from phthisis. 6. Limb flexed and required artificial support. 7. Excision and amputation. 8. Amputation. 9. Death from scarlet fever three months after operation, with wound unhealed. 10. Amputation. 11. A year afterwards limb flexed and required support of a Thomas's splint. 12. Stiff limb, sound and well. 13. Unhealed five months after operation. 14. Unhealed four months after operation. 15. One month after operation healed; much pulpy disease. 16. Excision." These results speak for themselves.

Arthrectomy is still on its trial, and is not by any means a well-established operation; nevertheless, I believe that in certain well-selected cases, where the disease is limited to the synovial membrane, erasion is preferable to excision; and I am acting up to that belief in my practice, expecting, on the one hand, that whilst in certain cases I shall have better results than if I had excised, on the other I shall have a smaller number of failures than I should have in an equal number of excisions.

Illustrative of the difficulty of being certain that the disease is limited to synovial membrane, I will mention a case that came under the care of one of my colleagues at the Leeds Infirmary. My friend, Mr. Ward, was excising a knee-joint on account of disease which appeared to be limited to the synovial membrane, the articular cartilage and bones being apparently healthy; but on examining the excised part of the femur, a nodule of tuberculous granulations, about the size of a pea, was found beneath the articular cartilage. Had this joint been erased instead of excised, the probability is that the disease would have returned, necessitating excision or amputation. I am sorry if my remarks, too much epitomised, should have misled anyone, but I trust that this fuller explanation of my views will render my meaning clear.

I am, Sir, yours, faithfully,

Hillary-place, Leeds, Jan. 7th, 1886. A. W. MAYO ROBSON.

THE "TUBERCLE BACILLUS."

To the Editor of THE LANCET.

SIR,—In your issues of THE LANCET of Nov. 28th and Dec. 5th I find two articles having the title of "Tubercle and the Tubercle Bacillus, a Review," on which, with your permission, I wish to make one or two remarks. Without introduction, I observe at once that I receive the writer's history of the bacillus, but I am quite at issue with the general tenour of his deductions, believing, as I do, that there are many causes of tubercular disease, and that the tubercle bacillus, so-called, has yet to be shown to be one of them; for if the tubercle bacillus be the chief cause of tubercular disease—nay, truly, the only cause—i.e., the cause without which it cannot exist,—I ask how it can be that at the Brompton Hospital phthisis does not occur among the attendants (physicians, nurses, and others) more frequently than in our general hospitals, or among people outside? The writer of the articles states that the tubercle bacillus is present in the wards of a consumption hospital and in the breath of phthisical patients, yet neither contagion nor infection is more prevalent here than in any other place; nay, indeed, much less prevalent than in many places one could name. And it may be further observed that the observation respecting the freedom of the attendants at the Brompton Hospital from consumption was made long before the bacillus was dreamt of, and therefore before any unusual precautions were taken in the way of prevention.

I observe that the writer of the articles brings forward certain reasons for their escape; but in my judgment they do not meet the case, if, indeed, they (the attendants) are daily living and working in an atmosphere laden, as is stated, with infectious matter. I am really concerned at the thought of the amount of time and ingenuity which in this day is spent—wasted I had almost said—over "cultivations," so-called, of various and most wonderful microscopic entities; and I will venture to predict that before many years roll away we shall look back on the whole thing with regret and wonder at our folly. I remain, Sir, yours obediently,

King's Lynn, Norfolk. WM. DALE, M.D. Lond.

ON A PARTICULAR USE OF THE THUMB-NAIL IN LATERAL LITHOTOMY.

To the Editor of THE LANCET.

SIR,—Will you allow me to offer a description of a particular method of using the thumb-nail in lateral lithotomy, which I have practised for some time with advantage.

The vertical plane in which the thumb-nail lies when the hand is raised semi-prone in front of the face contrasts advantageously with the horizontal plane of the index-nail in the same position of the hand. With the thumb-nail in the groove in the staff the elbow may remain in its natural position, while with the index-nail there the elbow must be raised at least to the horizontal—a somewhat awkward manœuvre. The second source of advantage consists of the guidance the thumb-nail gives to the knife on being deeply pressed into the integuments covering the staff groove so as to define it (or at least one edge of it, if it be laterally grooved); along the nail thus planted the point of the knife can be slid with much precision in thin subjects and the majority of children, with the comfortable assurance of immediate arrival at the groove (i.e., in the operation about to be allnded to). In very fat subjects, though I cannot speak from experience, I have no doubt it would be found helpful, as I should think even then a wide-grooved staff could be fairly defined from without by a moderately long thumb-nail.

The operation I have now in view is the transfixion one, consisting of entry of point of knife in raphé at middle of perineum and transfixing till staff is reached. The authorship of this improved operation I cannot speak of with

Digitized by Google

certainty, but can only say I adopted it, and have practised no other since reading the description of it by Dr. H. W. Boyd in his valuable report on lithotomy cases in the Bombay Medical and Physical Society's Transactions, 1882.

Another addition to the transfixion operation, which I have found useful is the subcutaneous incision of the urethra by a back and forward sawing movement for a convenient length, for the thumb-nail, on its subsequent introduction into the wound, to easily find the exposed staff. On accomplishing this and re-introducing the knife on it, I withdraw my thumb, take the staff in my own hand (as advised by Harris in his work on Lithotomy), and proceed with the deep incision.

I am, Sir, yours faithfully,

FREDK. C. BARKER, M.D., F.R.C.S.I.,
Surg.-Major, Bombay Medical Service; Civil Surgeon, Kathiawar.

Rajkote, Kathiawar, Dec. 23rd, 1885.

"VISITORS TO SMALL-POX HOSPITALS."

To the Editor of THE LANCET.

SIR,—I gather from the paragraph in THE LANCET of the 9th inst. under the above heading that it is the habit to admit persons to see relatives in the Metropolitan Asylums Board Small-pox Hospitals without revaccination, that consequently it is observed that "a certain number" of such persons turn up in thirteen days as small-pox patients, and that as a deduction from his observation of these facts in connexion with the Western Hospital, "Mr. Sweeting suggests that since nothing short of the compulsory revaccination of all visitors to the small-pox wards will get over the difficulty, submission to that operation should be invariably insisted upon."

I am impelled to ask why the superintendent of a small-pox hospital should have to "suggest" such a rational proceeding. When I found myself in that position twenty years ago, I made it a rule absolute, without saying anything to anybody, and it has been rigidly followed to this day in Glasgow. Visits are minimised to the case of serious illness or of convalescence in the open air, and no relationship or other pathetic sentiment is ever allowed to obviate the condition of revaccination. Of course we have therefore never had those experiments on the incubation period of small-pox. I am, Sir, your obedient servant,

JAS. B. RUSSELL,
Medical Officer of Health of Glasgow.

Sanitary Department, Glasgow, Jan. 11th, 1886.

LARGE CALCULUS.

To the Editor of THE LANCET.

SIR,—I notice in last week's LANCET that at a meeting of the Northumberland and Durham Medical Society it was mentioned that Dr. Morrison removed a calculus from a man's bladder weighing 1 lb. 6¾ oz. The interest attaching to this was that it was the largest stone ever removed during life, though the patient died on the fourteenth day. In connexion with this statement, I may mention that a few years ago Surgeon Joseph Hunter, I.M.S., removed by suprapubic operation from the bladder of a native in the Madras Presidency a calculus weighing over 25 oz. This stone is now in the museum at Madras. Surgeon Hunter said he did not publish the case, as he considered there was no merit in it, the patient having lived only three days after the operation. He at one time thought of bringing the stone home to the British Museum.

Yours very truly,

W. B. HUNTER, M.D.

Londonderry, Jan. 12th, 1886.

GASTROSTOMY FOR MASSES OF HAIR IN THE STOMACH.

To the Editor of THE LANCET.

SIR,—With reference to the list of published cases which I gave in my paper last week, Sir William Gull has been kind enough to call my attention to one which I had overlooked, and which was published by him in the fourth volume of the Transactions of the Clinical Society. It occurred in the practice of Mr. Carver. The patient was a married woman, aged thirty-two, who had had three children and two abortions, and died two days after giving birth to a dead seven months' child, the cause of death being incessant vomiting, which had commenced some time before her confinement. A mass of hair and string, weighing 5¾ oz. when dry, was found in her stomach. I am also able from Sir William Gull's paper to give the correct reference to Mr. George May's case. I thought that it was recorded in 1865; it should be *Medical Association Journal* of Dec. 28th, 1855. The mass of hair in this case weighed 26 oz. Possibly I have overlooked other cases; but there are, at any rate, eight deaths, without correct diagnosis or attempt at surgical relief. My own case and that of Schönborn, the only two operated upon, are alive and well, and it is to be hoped that no one in the future will be allowed to die, when operative relief is so easy and safe.

I am, Sir, faithfully yours,

J. KNOWSLEY THORNTON.

Portman-street, Jan. 11th, 1886.

"SANTONIN IN AMENORRHŒA."

To the Editor of THE LANCET.

SIR,—In a recent number of THE LANCET Mr. Whitehead of Manchester drew attention to the value of santonin in the treatment of amenorrhœa; and he hoped that others would test the potent or valueless influence of the drug. In your issue of the 9th inst., Dr. Routh states that he has tried it in twenty cases, in seventeen of which it failed completely. As a further help towards a definite knowledge of its value I may relate my own experience of it. Since the publication of Dr. Whitehead's article I have treated all the cases of amenorrhœa that have come under my notice according to the method suggested by him—viz., ten grains of santonin taken on consecutive nights, omitting, however, the morning saline purge. I have thus given it in twelve cases, the majority of them being chloro-anæmic. In eleven it signally failed, and in a few the powder produced some unpleasant symptoms. In one only was it successful—that is, the catamenia came on in the morning after taking the second powder, and lasted the usual time. As Mr. Whitehead has been so very successful in its use, and Dr. Routh and myself as equally unsuccessful, we must be guided as to its value by further experience. That it has some influence in starting a uterine flow (difficult though it be to understand how it acts) seems evident. How much that influence is will soon, I trust, be ascertained.

I am, Sir, yours truly,

E. R. WILLIAMS.
Senior House-surgeon, Macclesfield Infirmary.

Jan. 11th, 1886.

OPERATION FOR CATARACT: A NEW ANTISEPTIC.

To the Editor of THE LANCET.

SIR,—In a paper read before the Paris Academy of Medicine, M. Panas referred to the great success which had attended the operation for cataract, in his hands, even among gouty, rheumatic, or diabetic patients, by the use of a new antiseptic. This consists of a solution of Biniodide of Mercury, containing—

Distilled water	1 litre
Mercuric iodide	0·05 gramme
Alcohol at 90°	20 grammes.

That is to say, 20,000 parts of the solution contain one part of the salt, and 20 parts of 90 per cent. alcohol. The mercuric iodide is dissolved in the alcohol, and this poured into the water and the whole filtered. Mercuric chloride is said to possess much less antiseptic power, and to be more irritating than the iodide. The globe is thoroughly rinsed with the solution, which is thrown in by means of an apparatus resembling the drum-tube of a dropping-bottle, local anæsthesia being induced by cocaine. Panopthalmitis is almost entirely unknown in the author's practice consequent upon the employment of the antiseptic treatment; moreover, he has been able to do away with von Graefe's method (linear incision with iridectomy) and revert to the older flap operation, reserving the iridectomy for exceptional cases. The capsule of the crystalline lens is freely torn, or even completely removed by means of a special forceps. When the operation is finished, the interior of the eye washed, and

Digitized by Google

eserine distilled, the eye is dressed with an ointment containing 1 per cent. of benzoate of mercury spread on linen, over which pads of wadding are placed, the whole being kept in place by a bandage in the usual way. The first change of dressing is made in twenty-four hours, cure being effected in about seven days.

I remain, Sir, yours truly,

January, 1886. CHARLES H. PIESSE, M.R.C.S.

THE TREATMENT OF PERTUSSIS.

To the Editor of THE LANCET.

SIR,—Mr. F. W. Cory has done good service in adding his testimony to the use of carbolic acid in whooping-cough; but, from the tone of his communication which appeared in your issue of last week, he seems to have overlooked all previous evidence, as well as the fact of carbolic acid having been in general use in that complaint for several years. In the year 1875, Dr. R. J. Lee, speaking at a meeting of the British Medical Association held in Edinburgh, advocated the use of carbolic acid vapour in whooping-cough. In the same year, Dr. Burchardt, lecturer at the University of Berlin, and Dr. Rugg, of Clapham-road, wrote to the *British Medical Journal* advocating the use of carbolic acid vapour. In THE LANCET of July 13th, 1878, I recorded several cases which resisted every remedy but carbolic acid given internally and deposited about the house, under which the malady rapidly subsided. Whether this was the first public announcement of the internal use of carbolic acid in whooping-cough I am not in a position to state. The above methods of treatment are quoted in Dr. W. H. Day's work on "Diseases of Children," published in 1881; also in Squire's "Companion to the British Pharmacopœia."

I am, Sir, yours faithfully,

Aberystwith, Jan. 11th, 1886. T. D. HARRIES, F.R.C.S.

LADY PROBATIONERS.

To the Editor of THE LANCET.

SIR,—As lady probationers are now to be found in most of our general and children's hospitals, I very much wish to learn, through your columns, how their hours of day and night duty are arranged, as I know of an instance in a provincial hospital where they are at the earliest period of their training placed upon night duty continuously for seven and eight weeks at a time, possibly as a trial of their strength and powers of endurance, and undoubtedly prejudicial to their health, as it is more than any trained sick nurse is allowed to do when employed in private houses. If the intention be to disgust these young ladies at an early period, no better means could be suggested; and should they fall sick or fail in their duties during such a term of trial, neither matron nor staff can be surprised at it. Having once been a hospital surgeon myself, I was always most careful that my nurses' strength should not be overtaxed in order that my patients, equally with themselves, should not suffer.

I am, Sir, yours faithfully,

January, 1886. AN OLD HOSPITAL SURGEON.

*** Our correspondent's inquiry is very important, and will, we trust, receive satisfactory replies. It is to be hoped that the practice he cites as obtaining in a provincial hospital is exceptional. It certainly is most culpable.—ED. L.

THE BLACKWATER VALLEY.

To the Editor of THE LANCET.

SIR,—In reference to your annotation in THE LANCET of Jan. 2nd, concerning the Blackwater Valley, I can inform you that the Hartley Wintney Sanitary Authority, in whose district much of the southern side of the river lies, have long been making efforts to have the river cleansed. More than a year ago we tried to have the work done at the expense of the riparian owners on either side of the river. In the Hartley Wintney Union, as well as in the Farnham Union, which contains Aldershot, the consent of all the riparian owners could be obtained, but the scheme fell through by the refusal of owners in the Finchampstead Union. Efforts are now being made to force the three authorities to combine in this most necessary work. At the same time, I think this is a subject of far more than local interest, and ought to be taken up as an Imperial work, affecting as it does the Camp at Aldershot, the Military Colleges, and the Broadmoor Asylum.

I remain, Sir, yours faithfully,

AN EX-OFFICIO GUARDIAN OF THE HARTLEY WINTNEY UNION.

Blackwater, Jan. 13th, 1886.

LIVERPOOL.

(From our own Correspondent.)

HOSPITAL SUNDAY.

LAST Sunday, being the second Sunday in the new year, was, as usual, observed as Hospital Sunday, being its sixteenth anniversary in Liverpool. A more unfavourable day, so far as the weather was concerned, could hardly have been imagined, and yet it is a most gratifying circumstance that the collections show in many cases an increase over those of last year. It is probable that the total sum raised will be greater than that of last year, the Hospital Saturday Fund showing an increasing tendency, while there is a general impression that the long depression in trade is giving way to a more hopeful state of things, of which the hospitals will, it is believed, reap the benefit.

WAKES AND THE SPREAD OF SMALL-POX.

Liverpool contains, as is well known, a very large proportion of Irish poor, and, in spite of all the efforts of the Roman Catholic clergy, the disgusting and drunken revels, falsely called "wakes," still continue to be a scandal to the city and a fruitful source, in many instances, of contagion being spread. Last week a man and his wife were summoned before the stipendiary magistrate, under Section 126 of the Public Health Act, for exposing a child suffering from infectious disease. It appeared that Dr. Hope, the assistant medical officer of health, visited the defendant's house, and there saw the body of a child who had died from small-pox. In the house at the same time was another child, four years of age, who was also suffering from the same disease. Dr. Hope informed the mother and other relatives of the nature of the disease, and recommended the removal of the child to the hospital; instead of which, the child was taken away to some other house, and could not be found for some time, when it was sent to the small-pox hospital. Dr. Hope stated that ten cases of small-pox had occurred among the relatives of the family, which had been traced to the house of the defendants, and round the body of the dead child a crowd of persons were indulging in a "wake." Neither of the children had been vaccinated, and it was in order to avoid a prosecution that the child had been removed. The deceased child had no medical attendance, and was in a frightful state, and the parents tried to persuade the coroner that it had died of measles. The magistrate expressed his wonder that people who ought to know better, and even members of Parliament, could be found to support the system of non-vaccination. The mother was fined 40*s.* and costs, and, being unable to pay, was sent to gaol for fourteen days; the summons against her husband was dismissed. It is hoped that this case will act as a warning, as wakes on the victims of small-pox are now illegal.

Liverpool, Jan. 13th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE LATE ELECTION FOR CORONER.

THE late election for coroner by the Newcastle Council did not turn on the question of eligibility of a medical candidate for the office; but Mr. Newton found out before he retired that the feeling of the Council was very strong as to the office being given to Mr. Hoyle, son of the late coroner, who had acted as his father's deputy for many years. The question of medical or legal candidate was discussed very fully in our local newspapers, and of course with varied views. The *Newcastle Chronicle*, however, one of our

Digitized by Google

principal papers, was very decided in its opinion as to a preference for a medical coroner. It said: "In the election of a coroner, it is a moot question whether the office should be filled by a lawyer or a medical man. Speaking for ourselves, we would prefer the latter, inasmuch as the cases to be inquired into are for the most part of such a character as one having a knowledge of the human body can best deal with." Had the Newcastle Council been of the same opinion, their choice could not have fallen on a better man than Alderman Newton. In addition to medical knowledge and experience on the bench, he possesses, what is scarcely of less value for the due fulfilment of the office, a thorough knowledge of the life of the district to be served, its people, their ways and manners.

THE PROPOSED HOSPITAL FOR CHILDREN AT GATESHEAD.

The proposal to erect a hospital for children at Gateshead is meeting with great encouragement. Lady Northburne has given a site near the Boy's High School, Durham-road, consisting of two acres. For some time past the need of such a hospital has been felt, in order that children might have more exclusive attention. A beginning, it is to be hoped, will soon be made now with the building.

DEATH UNDER CHLOROFORM AT NEWCASTLE INFIRMARY.

I regret to say that the death took place at the Newcastle Infirmary on the 7th inst. of a patient who had been placed under chloroform by direction of the house-surgeon for the purpose of having an abscess of the face opened. It transpired at the inquest that the patient, who was a delicate woman aged thirty-five, became unconscious in about half a minute; after one drachm had been inhaled the breathing suddenly stopped, and all efforts to restore consciousness proved futile. This being the third fatal case in the Newcastle district in about three weeks, it has of course produced a very painful impression on the public mind. The verdict of the jury was that the patient had died while under chloroform from failure of the heart's action, and that there was no blame attached to anyone as to the administration of the chloroform.

NEWCASTLE THROAT AND EAR HOSPITAL.

The annual meeting was held on the 8th inst., the Mayor presiding. It was shown that nearly 2000 patients had been treated during the past year. The patients had contributed more than £200 to the funds of the hospital. The hospital was free from debt, and had an invested capital of £150 as a nucleus for its extension, which was necessary.

Newcastle-on-Tyne, January 12th.

EDINBURGH.

(From our own Correspondent.)

CLINICAL INSTRUCTION IN FEVER.

IN connexion with the proposed arrangement for conducting clinical teaching at the Fever Hospital, it was decided at a recent meeting of the Public Health Committee that a deputation representing the University and the Extra-academical Medical Schools should be asked to wait upon the Town Council and discuss the matter. At a meeting of the Town Council held last Tuesday the question came up for discussion. A letter was read from Dr. Claud Muirhead as representing the wishes of the extra-mural lecturers on the subject. Their views had already been fully expressed in a prior communication to the Public Health Committee, and they were unwilling to trespass further on the time of the Council at large by sending a deputation, but were perfectly prepared to leave the matter entirely in its hands. A deputation from the University, consisting of Professors Grainger Stewart, T. R. Fraser, and Rutherford was then introduced. The proposals of the University authorities are, for the most part, identical with those of the extra-academical teachers. The University proposition is that two ordinary physicians shall be appointed, one connected with the University and one connected with the extra-mural School. The control of the hospital wards would be equally divided between these two officers, whose duty it would be to conduct clinical instruction for students visiting the wards, and to superintend the treatment of the patients. In case of there being at any time very few inmates of the hospital, the two acting physicians might alternately take charge of the whole for periods o three months at a time. The only points in which difference of opinion cropped up between the ideas of th University authorities as expressed by their deputation an those of the extra-mural lecturers was in regard to th number of physicians to be appointed and the system o remunerating them for their services. The University hold that this should be provided for by fees payable by the student attending the Hospital. As Professor Stewart put it in hi speech—"What was worth having was worth paying for and the students were none the worse for paying a small fee." The extra-mural lecturers, on the other hand, urge that only one physician should be appointed, that an honorarium should be provided for him apart from students' fees, an that all students of the school, whether matriculated at th University or not, should have access to hospital instructio entirely free of charge. In reply to a question from th Lord Provost, Professor Grainger Stewart expressed a opinion in favour of making the proposed course of instruc tion a necessary part of the University medical curriculum A deputation from the Students' Representative Counci was afterwards received by the Town Council, and th arguments adduced were in the same sense generally a those propounded by the professors. The matter, having thus been thoroughly ventilated, was remitted to the Public Health Committee for final adjustment. Several very important principles are involved in their decision. Perhaps the most serious aspect of the matter is the proposal to add another to the already long and lately greatly expanded list of subjects which have been made compulsory, and to which has been superadded a very appreciable increase in the fees payable; and all this without any recommendation or even suggestion by those in authority of a prolongation of the period of study. A single additional fee and a single additional subject are not in themselves very serious matters to the student; but when these single additions are made in rapid succession, as has lately been the case, there is a great danger of the burden becoming too oppressive even for the much-enduring student of the modern *régime*. An addition to the number of optional classes, so as to provide a fair representation for the claims of important specialities, is a great desideratum, as ensuring the development of a broader academic spirit; but such new growths as these should be sustained by nutritive arrangements of their own, and should not exist merely parasitically by drawing sustenance from the already well-drained vital currents of student life. If the Public Health Committee make arrangements which will tend towards the former result, they will confer a boon on the school which it is their desire to benefit; if towards the latter, it is to be feared that these long-wished-for facilities of instruction will not bring with them the unmixed benefit which it ought not to be utopian to hope for.

ROYAL MATERNITY HOSPITAL

Professor Simpson, who has been physician on duty at this hospital during the last three months, will be succeeded on Feb. 1st by Dr. Angus Macdonald for the ensuing quarter. Messrs. T. W. Dewar, M.B., and D. M. Moir, M.A., M.B have been appointed house-surgeons for that period.

SICK-ROOM COOKERY.

A most useful course of demonstrations under the auspices of the Edinburgh School of Cookery is about to take place in the large theatre of the Royal Infirmary. A series of the most valuable sick-room delicacies are prepared and cooked in the presence of the students by lady demonstrators, who are adepts alike in the arts of cooking and of teaching. The course comprises a great variety of useful details, which must prove of great service to the practitioner in arranging for this very important factor in the successful treatment of his patients.

Edinburgh, Jan. 13th.

ABERDEEN.

(From our own Correspondent.)

VOLUNTEER MEDICAL STAFF CORPS.

A PUBLIC meeting was held on Saturday, the 9th inst., to consider the proposal to form a Volunteer Medical Staff Corps. Lord Provost Matthews presided, and a number of prominent citizens who were present formed themselves

Digitized by Google

into an Ambulance Association to forward the scheme, by first obtaining the guarantee fund of £100, and afterwards to further the development of the ambulance system, so that a number of representative men from the various public works in and around Aberdeen should receive instruction in ambulance work, and thus there would be "a regularly trained body of men spread over the town who would be of great service in case of serious accidents." At first only medical students are to be enrolled as members of the corps, and already more than the requisite number have given in their names. Professor Ogston and Drs. McKenzie Booth and MacGregor are to be proposed as officers.

THE ROYAL INFIRMARY.

Another expert has been called in to help the managers to make up their minds as to what they should do in the case of the Infirmary. Mr. Saxon Snell inspected the present buildings and site on Saturday, and met the House Committee on Monday, when he laid before them a scheme whereby accommodation could be found for 250 beds, and a further extension if necessary could be made so as to give 300 beds altogether on the present site, infectious diseases to be excluded. He proposes building three pavilions behind the present building, which is to be given up to administrative purposes. He recommends 1300 cubic feet, but if required can provide 1500 cubic feet per patient.

INSPECTOR OF DISEASED MEAT.

The Public Health Committee have resolved to recommend the Town Council to appoint an "inspector of unwholesome food of all kinds," who shall devote his whole time to the work, with a salary of £125 per annum. At present Dr. Simpson performs the duties, and receives £30 per annum.

[redacted], Jan. 13th.

IRELAND.

(*From our own Correspondent.*)

[redacted] ROYAL UNIVERSITY OF IRELAND.

[redacted] Senate, at a meeting last week, adopted a resolution expressing their deep regret for the loss the University has sustained by the death of its first Chancellor, the Duke of Abercorn, K.G., and they directed that the expression of their sympathy should be conveyed to the Duchess and the other members of the family. The Senate have fixed Tuesday, April 6th, as the date for holding a meeting of convocation for the election of a person to fill the vacancy in the Senate which will then arise by the expiration of the period of three years for which Mr. Farrelly had been elected. Mr. Farrelly is a candidate for re-election, and probably will be opposed in consequence of his action during the recent election for a member of the Senate. At the same meeting the Senate reappointed the various examiners in medicine who conducted the medical examinations last autumn. At a public meeting of the University, held on the 7th inst., the degree in Obstretrics was conferred upon Drs. Maurice H. Curtin and James Whitton, and diplomas for proficiency in the treatment of mental diseases were granted to Patrick Arthur Daly, M.B., and Wm. Henry Thompson, M.D.

[redacted] QUEEN'S COLLEGES, IRELAND.

[redacted] Educational Endowments Commission last week counsel appeared on behalf of the Crown, and submitted that the Queen's Colleges of Belfast and Galway should be exempted from the provisions of the Act. The question having been argued at considerable length, Lord Justice Fitzgibbon, in giving judgment, said they had very little difficulty in dealing with the matter. The moneys annually voted by Parliament upon the estimates did not become appropriated in any way for the purposes for which they were applied until they were dealt with by the Appropriation Act; and such money, therefore, not constituting in fact property at all until it was absolutely appropriated by the supreme authorities of the country, could not, as it appeared to the commissioners, come under the description of property dedicated to charitable uses, or which was applicable to educational purposes. Therefore, as regards these annual votes, there could be no doubt whatever that they did not constitute property with which they could deal [redacted] under this Act. The next portion of the grant was the £33,000 a year appropriated under the original [redacted] to each College. The fund was one which depended for its existence upon the power vested in the Lords of the Treasury to make the charge upon the consolidated ground. This, again, was not property dedicated to charitable uses or applicable to educational purposes, until their power to appropriate it was first exercised by the commissioners of Her Majesty's Treasury. The third-class of property was in a different position—namely, the buildings, which were originally provided by Parliament by money obtained through the action of Parliament, and as the sites of these buildings and as property was acquired it became vested in the Board of Works upon trust for the Queen, and if it had remained so he did not think there could be any doubt that the Act did not apply, but they had been handed over by the charter of 1863 to the governing body of the Colleges, composed of the president and professors. It would, therefore, occur to them that they plainly came within the words of this Act of Parliament in so far as the buildings were concerned. The commission would be administered with a view to what was practicable as well as to what was legal. There was no compulsion upon the commissioners to settle schemes, and he need not say that the settlement of a scheme for the bare buildings of the Queen's Colleges would be perfectly useless. They had no intention of initiating proceedings regarding the endowments of these Colleges until further orders.

DUBLIN BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

The ninth annual general meeting of this branch will be held at the College of Physicians on Thursday, the 28th inst., when the officers and council for the ensuing year will be elected, and any other necessary business transacted. The president-elect, Mr. Bennett, will deliver the annual address, and the members and their friends will dine together the some evening in the hall of the College.

AMPUTATION THROUGH THE HIP-JOINT.

Mr. J. Kellock Barton performed this operation on last Tuesday at the Adelaide Hospital, the method adopted being that suggested by Mr. Furneaux Jordan of Birmingham. The patient some years since had the os calcis removed at another hospital for disease of the foot; but, the disease spreading, amputation was performed through the lower part of the thigh by Mr. Barton. Ether was administered, being the anæsthetic usually given in this hospital. I reported in THE LANCET about a year since a similar operation by Mr. Barton, which turned out very satisfactorily; the patient, however, succumbed from an attack of measles.

Dublin, Jan. 12th.

PARIS.

(*From our own Correspondent.*)

THE ANTISEPTIC TREATMENT OF CATARACT.

PROFESSOR PANAS read a very interesting note at the recent meeting of the Academy of Medicine on the Advantages of the Employment of the Antiseptic Method in the Treatment of Cataract. "Thanks to it," said the Professor, "we are enabled to give up the linear incision of Von Graefe with iridectomy, and to return to the old method with flaps, reserving iridectomy for exceptional cases." Of all the antiseptics that have been employed in man, Professor Panus gives the preference to a solution of the biniodide of mercury as follows: Biniodide of mercury, 0·05 centigramme; alcohol at 90°, 20 grammes; distilled water, 1 litre. The biniodide is thus rendered soluble, and the solution may be preserved indefinitely. It produces no irritation of the conjunctiva; it is well tolerated, except in some rare cases, when it is injected into the interior of the eye. At the moment of operation the globe of the eye should be anæsthetised by the application of cocaine; then the capsule of the lens should be freely opened—it should even be removed by the aid of special forceps. The operation over, the eye should be washed interiorly and the dressing applied, after having previously instilled a solution of eserine into the eye. For this dressing, M. Panas covers the eye with a piece of linen greased with an ointment composed of one gramme of the benzoate of mercury to 100 grammes of white ointment. With this method, M. Panas has been able to operate without any inconvenience on diabetic, gouty, and rheumatic subjects—in short, on all such as would be in an unfavourable condition for the success of the operation.

THE DEVELOPMENT AND HEALTH OF RECRUITS.

At the same meeting Dr. Lagneau read a paper on the conditions necessary for recruiting soldiers in the French army in regard to the development of the human body. After consulting various statistical documents, Dr. Lagneau has been led to the conclusion that a great number of men reach their maximum height at the ages of twenty-three, twenty-five, and thirty, according to race. In France the inhabitants of certain departments, formerly peopled by Celts, reached their maximum height very late. "Physiological misery," resulting frequently from insufficient food and other depressing causes, also retards physical development in height and breadth. The development of the chest is also never completed before the age of twenty-five or twenty-eight, that in those of young men brought up to a sedentary life being notably less than that in those who follow active occupations. Although the physical development is not complete at the age of twenty, yet Dr. Lagneau thinks that it is sufficiently so to permit the men to receive military instruction. Although the mortality in the French army is considerably less than it used to be, yet the soldiers present about double the number more of patients, and about half as many more of deaths, as among civilians of the same age. This, I presume, is the proportion in time of war, as Dr. Lagneau states further on that the military mortality in time of peace is from 8 to 10 per 1000 of the effective, which differs little from that among civilians. Two maladies commit great ravages in the army—typhoid fever and tuberculosis,—resulting principally from aggregation and defective ventilation, and are more rife in barracks located in towns than in those in rural districts. Dr. Lagneau refers to many other points, which for want of space cannot be entered into here; I may, however, mention that he is in favour of short service in the army, so as to give the population a better chance of being increased.

SMALL-POX AT TOULON.

Reports have reached Paris to the effect that a violent epidemic of small-pox has broken out at Toulon, and that many deaths have occurred from the disease. The panic is very great among the inhabitants, and several of the medical men have offered their services gratuitously to vaccinate those who are desirous of undergoing the operation.

THE PRIX MONTYON.

At the last distribution of prizes at the Academy of Sciences M. Girard, the Director of the Municipal Laboratory, was awarded 2500 francs of the Prix Montyon for his report on Adulterations of Food.

Paris, Jan. 12th.

ROYAL COLLEGE OF SURGEONS.

AT a quarterly meeting of the Council held on Thursday last, the Council authorised the expenditure of £40 on some models of fossil specimens of the Pterosaurs, which have been obtained from Munich.

The resolution passed at the general meeting of Fellows and Members, which was held at the College on Dec. 17th, was reported by the President, and the resolution read. Upon that, by permission of the Council, without giving notice of the motion, Mr. Macnamara moved, and Mr. T. Smith seconded, "That a committee be appointed to ascertain and report to the Council the opinion of the Fellows as regards the advisability of Members being allowed to vote for the election of Fellows as members of the Council." To this the following amendment was moved by Sir James Paget, and seconded by Mr. Cooper Forster: "That the consideration of Mr. Macnamara's motion be deferred until after the report of the Committee on the Conditions of Admission to the Fellowship has been presented to the Council." This was carried *nem. con.* It was afterwards carried as a substantive motion.

Mr. Savory was appointed Hunterian Orator for the year 1867.

PRESENTATION. — Dr. Moore, Medical Superintendent of the Chelsea Infirmary, was on New Year's Eve presented by the officers of that institution with a handsome silver-plated biscuit-case and a set of silver-plated salt-cellars as a mark of their appreciation of the efforts which he had always made for their welfare.

Obituary.

KELBURNE KING, M.D., F.R.C.S. EDIN. & ENG.

DR. KING died suddenly at his residence in Hull on the 2nd inst., the cause of death being rupture of a thoracic aneurism. The son of the late Captain King, R.N., Spring Bank House, Kilmalcolm, Renfrewshire, he was born in January 1823, and was thus only sixty-three years of age at the time of his lamented death. He was educated at the Edinburgh University, where he graduated as M.D. in 1844. In his student days he not only distinguished himself as a pupil of the late Sir William Hamilton, but was also associated with the late Dr. Robert Knox as Demonstrator of Anatomy. Dr. King was, moreover, a favourite pupil of the late Professor Syme, with whom he maintained a firm friendship until the death of the latter. He was elected to the Fellowship of the Royal College of Surgeons of England (*ad eundem*) in 1870 as "a tribute to his reputation and professional attainments." As surgeon to the Hull Royal Infirmary since 1858, he laboured assiduously for its reputation, and a vast number of grateful patients have experienced the benefit of his masterly professional services. It was, however, not only to his qualities as an eminent and gifted surgeon that Dr. King's reputation was due in his adopted town; he had there filled many public offices with that energy and success which he carried into all his works. He was President of the Hull Literary and Philosophical Society, 1864-69 and 1872-75, and during those periods many eminent men who lectured before the Society found at his house a kindly welcome, the genial hospitality of their host being always extended on such occasions to many private friends. Dr. King was an alderman, and had been thrice Mayor of the borough, and only last year filled the office of Sheriff. He entered the Town Council with a view mainly to the advancement of sanitary improvements, and was instrumental in effecting many, his scientific acumen and fluent speech always exercising great influence upon those who were brought in contact with him. His funeral took place in Hull on the 6th inst., and was attended by the Mayor and Corporation, the Brethren of the Trinity House, the members of the Board of the Hull Infirmary, besides an immense concourse of people of all classes and shades of opinion, who were moved by deep sympathy and the respect in which he was held to join in the funeral ceremony. Of him indeed it may be truly said, "He filled his course of life with deeds, and not with lingering years"; and though the grave has closed over him, he will long survive, not only in the local memory of his townsmen, but also in the loving remembrance of a far-reaching circle of friends.

MR. JOHN BLACKETT JEAFFRESON, M.R.C.S., L.S.A. (OF HIGHBURY.)

THE profession and the public of Highbury were much shocked on Wednesday by the announcement of the death of Mr. Jeaffreson, of 145, Highbury New Park, and of the well-known and much-respected firm of Jackson, Jeaffreson, and Peignand. Mr. Jeaffreson's health for some years had been impaired by diabetes, but he was out so lately as Saturday last. He felt the cold severely, and had been heard to say that he feared it would be fatal to him. On Sunday he did not feel well. Symptoms of indigestion, with irregularity of the heart and an extreme sense of exhaustion, gave his friends much concern. He seemed better on Monday morning, but, in spite of the exertions of his partners and of Dr. Pavy, the sense of exhaustion returned and increased, and he died early on Wednesday morning, to the great grief of a large circle of friends and patients, by whom he was much esteemed. Mr. Jeaffreson's name is an honourable one in the north of London. His father, Mr. John Furrance Jeaffreson, preceded him in partnership with Mr. Jackson, and he was the nephew of the late Dr. Henry Jeaffreson, of Finsbury, who was in very large consulting practice. He leaves a widow, one daughter, and three sons to mourn their loss. One son at least, we believe, is likely to perpetuate the credit of the name in medical practice.

FREDERIC GILDER JULIUS, M.D., F.R.C.S.

WE regret to have to record the death of Dr. F. G. Julius, which took place on the 4th inst., at Richmond, Surrey, in the seventy-fifth year of his age, from pneumonia. Deceased was born in Bristol in February, 1811, and shortly afterwards his father removed to Richmond to join Sir David Dundas, then Serjeant-Surgeon to George III., in practice; here he was subsequently joined by his two sons, Dr. George C. Julius (who predeceased his brother by only one month), and the subject of this notice. Dr. Frederic Julius was educated at St. George's, and in 1833 he became a member of the Royal College of Surgeons and licentiate of the Society of Apothecaries; in 1851 he received the degree of M.D. Lambeth, from the Archbishop of Canterbury; and in 1853 he was elected an Hon. Fellow of the Royal College of Surgeons. Dr. Julius's name was at one time prominently before the public as the principal medical witness against the prisoner at the Smethurst trial. He ultimately retired from practice in 1871, and afterwards spent much of his time abroad, visiting upon different occasions most of the countries bordering upon the Mediterranean.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 11th inst., and when eligible will be admitted to the Pass Examination:—

ANATOMY AND PHYSIOLOGY.—Arthur A. F. Fletcher and Henry W. Bryant, Melbourne University; H. Grier and Thomas O. Williams, Dublin; William S. Crawford and Ernest A. Steele, Liverpool; W. Kenneth Mackenzie, King's College Hospital; John R. Wood and Frederick W. Mais, Leeds; John Farrington and Guy H. Woods, Manchester; Frederick Dymoke, Bristol School of Medicine; Thomas S. Coombe and Frederick N. Burwell, Cambridge University.

ANATOMY ONLY.—Samuel E. C. McDowell, Toronto; Walter F. W. Wilding, Liverpool; Charles A. Morgan, St. Thomas's Hospital; John T. Bradley, Manchester.

PHYSIOLOGY ONLY.—James S. Tait and Henry L. Green, Pennsylvania; Frederick A. Foy, Bombay and Aberdeen; James S. Fox, Liverpool; John H. Murray-Aynsley, St. George's Hospital; Henry Walter, Dublin.

Passed on the 12th inst.:—

ANATOMY AND PHYSIOLOGY.—David R. P. Evans, Charing-cross Hospital; H. G. Collett, King's College Hospital; David A. Birrell, St. Mary's Hospital; Patrick O. Thompson, Joseph Nall and Charles H. Cosens, St. Bartholomew's Hospital; William Griffiths, Melbourne and University College Hospital.

ANATOMY ONLY.—William G. Beyts and Arthur B. Hudson, Guy's Hospital; Arthur H. Howell, London Hospital; Herbert Lloyd, University College Hospital.

PHYSIOLOGY ONLY.—Walter L. A. La Croix, Bristol Medical School; Richard F. Hiley, Cambridge and St. Thomas's Hospital; Arthur C. J. Macann, James W. Hudson, and Louis P. Gibson, Middlesex Hospital; John W. Jessop, Edward P. Furber, and Sidney L. Hinde, St. Bartholomew's Hospital; Thomas G. J. Moore, Charing-cross Hospital.

The Library of the College will be closed to-day (Friday), for the purposes of the Pass Examination for the Membership, for which 280 candidates have entered.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on the 7th inst.:—

Kaka, Sorabji Manekji, M.R.C.S., L.R.C.P., Bombay.
Weaver, John James, Hoghton-street, Southport.

On the same day the following gentlemen passed their Primary Professional Examination:—

Fletcher, George Rory John, Charing-cross Hospital.
O'Connor, Wm. Patrick, University College.

THE death of a boy has recently been caused by the bite of a cat.

THE Red Crescent Society in Turkey is being reorganised by the Sultan's private physician, Dr. Mavroghéni Pacha, so as to be in a condition to assist the army in the field.

SANITARY CONDITION OF MARYLEBONE.—At a meeting of the Vestry of St. Marylebone on the 7th inst., the sub-ject of the sanitary condition of certain districts was considered, and some startling disclosures made respecting them. It was resolved to appoint a special committee to investigate, and suggest measures for the improvement of, the sanitary condition of the parish.

MEDICAL MAGISTRATE.—T. D. Harries, F.R.C.S., L.R.C.P. Lond., has been placed on the Commission of the Peace for the Aberystwith district.

THE PARKES MUSEUM.—On Thursday, Jan. 21st, at 8 P.M., a lecture will be delivered by Mr. R. F. Grantham, on "The Working of the Separate Sewage Systems," Prof. W. H. Corfield, M.A., M.D., in the chair.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund held on the 12th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £71 was distributed among the several applicants.

A WARD at the Leeds General Infirmary has just been furnished and opened for the reception of patients suffering from the diseases peculiar to women. A maternity charity, too, has been organised.

SANITARY ASSURANCE ASSOCIATION.—At the Parkes Museum of Hygiene, on Jan. 20th, at 8 o'clock, Professor T. Roger Smith, F.R.I.B.A., will read a paper on "A Damp House," Sir Joseph Fayrer, F.R.S., in the chair.

IT is proposed to erect, at a cost of £20,000, a new Bath Hospital and Convalescent Home at Harrogate. Accommodation will be provided for seventy-five patients in the hospital and for fifty in the convalescent home.

THE final list of the Newcastle-on-Tyne Hospital Sunday collections taken last October, shows that in the two departments the amount received is slightly over £3400, a small increase compared with the total received in the previous year.

ROYAL MEDICAL BENEVOLENT COLLEGE.—The amount collected at the sermon preached by Archdeacon Blunt, D.D., in the church of St. Mary Bishophill Senior, York, on the 7th inst., on behalf of the Epsom College, amounted to £26 1*s* 10*d*.

A SMALL-POX epidemic has recently declared itself in the slums of Marseilles, and the municipality have ordered the immediate creation of eight vaccine dispensaries. M. Pasteur and the veterinary establishment at Alfort have been applied to for a supply of vaccine matter.

QUARANTINE IN TURKEY.—The forty-eight hours' observation on arrivals at Conttantinople from Trieste has been abolished, and vessels from that port will in future be subjected to medical inspection. The quarantine on arrivals from Venice has been reduced to forty-eight hours. Vessels from Spanish ports will undergo ten days' quarantine.

ST. JOHN AMBULANCE ASSOCIATION.—A further series of lectures have been arranged for the police force belonging to the East and West India Dock Company, the lecturers appointed being members of the medical staff of the Poplar Hospital. Since these classes were started in 1879, 2438 accidents have occurred within the Dock premises, in many of which valuable assistance was rendered by students at the ambulance classes.

VOLUNTEER MEDICAL STAFF CORPS.—A crowded and enthusiastic meeting was held at Woolwich on the 11th inst., to promote the extension of this corps of voluntary workers, for the purpose of aiding the study and development of ambulance and hospital corps organisation. Addresses were delivered by Sir Thomas Crawford, Colonel Stewart, and others, and a resolution pledging the meeting to support the formation of a corps was carried unanimously.

TEMPERANCE IN AMERICA.—At a meeting held on the 12th inst., at Prince's Hall, Piccadilly, the Venerable Archdeacon Farrer, D.D., gave an interesting account of his experience of the temperance legislation which exists in some parts of America. There are no less than five States of the thirty-six which have adopted a stringent measure of absolute prohibition, which has been productive of most beneficial effects. In the State of Maine the prohibitory law has been in force twenty-two years, and there is only one convict to every 1000 of the population; whereas in Massachusetts, where there is no liquor law, there is one convict to every 500 of the population. In Trimble county, Kentucky, which has adopted the liquor law, during the last year there has not been a single criminal case, not a single prisoner in the gaol, and not a single pauper in the county. Kansas adopted the prohibitory liquor law in 1881, and during nine months of 1880, when it was under free whisky

Digitized by Google

rule, there were 264 convicts, while in nine months of 1881, when the prohibitory liquor law was in force, the number of convicts was only 148; and in a town in Illinois, with a population of 2500, there had not been a single arrest in twenty months.

A NARROW ESCAPE.—On the 8th inst., as Mr. Le Page of Salford was passing over a level railway crossing, a train of trucks, with an engine at the back, ran across the street. The buffers of the front waggon struck Mr. Le Page's brougham, one on the door and one on the box. The carriage was overturned and driven by the train for twenty or thirty yards, the horse being dragged by the side of the truck. Mr. Page was extricated from the débris after an imprisonment of about ten minutes.

THE DANGERS OF CHLORODYNE.—An inquest was held on the 12th inst. on the body of a woman who, together with her two sisters, had been in the habit for some years of taking chlorodyne in large quantities. The result was their bodies had become emaciated, their mental condition affected, and the use of their limbs impaired. In the present case the body of the deceased, who was sixty-two years of age, did not weigh more than 50lb. The jury returned a verdict in accordance with the evidence.

A HEALTH DEPARTMENT FOR JAPAN.—A Health Department has been established in Japan under Dr. Mansanori Agata, Professor of Hygiene in Tokio, who studied for several years in Munich, Leipsic, and Berlin, and in particular worked for a lengthened period in the laboratories of Pettenkofer and Koch. Since his return to Japan he has carried out the German methods of bacteriological research, and has by this means investigated the disease beri-beri, which is indigenous to Japan.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The following members were elected as officers for the year 1886 at the annual meeting on the 11th inst.:—President: Mr. T. Charters White. Vice-Presidents (resident)—Messrs. G. Gregson, H. Sewell, S. J. Hutchinson; (non-resident)—Messrs. Richard White (Norwich), Andrew Wilson (Edinburgh), Richard Rogers (Cheltenham). Treasurer: Mr. James Parkinson. Librarian: Mr. Felix Weiss. Honorary Secretaries: Messrs. David Hepburn (Council), Robert H. Woodhouse (Society), Willoughby Weiss (for foreign correspondence).

CLINICAL SOCIETY.—The annual general meeting elected the gentlemen nominated by the Council to serve on the various offices during the ensuing year (*vide* THE LANCET, p. 45). The scrutineers of the ballot were Dr. C. E. Beevor and Dr. H. M. Murray. The report of the Council was read by Mr. R. J. Godlee. The resolution that the Treasurer's report be received, adopted, and printed in the Transactions was moved by Mr. Harrison Cripps, and seconded by Dr. Angel Money. The vote of thanks to the retiring officers was moved by Dr. James Anderson, and seconded by Dr. B. O'Connor. Mr. J. H. Morgan responded.

OVERHEAD WIRES.—At the meeting of the Metropolitan Board of Works on the 11th inst., attention was drawn to the action taken by the Wandsworth Board of Works with reference to overhead wires, and it was resolved that the Works Committee be requested to inquire and consider as to the facts relating to the recent accidents to overhead telegraph and telephone wires and the danger to the public therefrom, and to report thereon, and as to the necessity of any proceedings or future legislation on the subject; and that the surveyors to the vestries and district boards be requested to supply the Board with any information which they have on the subject.

THE GORDON BOYS' HOME.—A general meeting of the Council of this institution was held on the 12th inst., at Marlborough House, under the Presidency of the Prince of Wales. Through the generosity of the War Office the committee had been enabled to open a temporary home at Fort Wellington, and at this place fifty boys are already in residence. The original idea was to establish a camp for 480 boys, and to spend on the building £12,000, and on furnishing £8000. It is now, however, not considered desirable to extend the operations to that amount, but it is the intention of the committee to arrange a camp for 120 boys, spending for this purpose about £6000. Further contributions are needed, and an effort is to be made during the present year to obtain them.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

DAKIN, WILLIAM RADFORD, M.D., B.S.Lond., M.R.C.P., has been appointed Physician to the Royal Hospital for Women and Children.

EVANS, A. E., M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed House-Physician to the Wolverhampton and Staffordshire General Hospital.

HOLLINGS, C. E., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Holme District of the Howden Union.

LEFTWICH, C. H., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the West Deptford Division of the Greenwich Union.

MOLINE, PAUL F., M.B.Lond., has been appointed Registrar to the Victoria Hospital for Children, Chelsea.

STUDDERT, R. C., M.D., has been appointed Medical Officer of Health by the Erith Local Board.

TURNER, PHILIP D., M.B.Lond., has been appointed House-Surgeon to the Victoria Hospital for Children, Chelsea.

WALKER, FRANCIS J., M.B., Cert. San. Science Durh., M.R.C.S., L.R.C.P.Lond., L.S.A.Lond., has been appointed Medical Officer of Health to the Spilsby Rural Sanitary Authority, vice J. West Walker, M.B.Lond., resigned.

Births, Marriages, and Deaths.

BIRTHS.

HUMPHREYS.—On the 9th inst., at Queen's-crescent, Haverstock-hill, N.W., the wife of F. Rowland Humphreys, M.R.C.S., L.R.C.P.Lond., of a son.

MOORE.—On the 12th inst., at Penlea, Shirehampton, Gloucestershire, the wife of George Moore, M.D., Deputy Inspector-General, Royal Navy, of a daughter.

ROBATHAN.—On the 5th inst., at The Grove, Risca, Monmouthshire, the wife of George Beckett Robathan, M.R.C.S., of a daughter.

TIRARD.—On the 9th inst, at Weymouth-street, Portland-place, W., the wife of Professor Tirard, M.D.Lond., of a daughter.

WADE.—On the 8th inst., at Beauclerc House, Harold-road, Upper Norwood, the wife of Charles H. Wade, B.A.Oxon., M.R.C.S., L.R.C.P., of a daughter.

WAGSTAFFE.—On the 6th inst., at Purleigh, St. John's-hill, Sevenoaks, the wife of W. W. Wagstaffe, B.A., F.R.C.S., of a son.

WORLEY.—On the 6th inst., at Green-lanes, N., the wife of W. Charles Worley, L.R.C.P.Lond., of a daughter.

MARRIAGES.

BROGDEN—RHODES.—On the 5th inst., at St. Paul's, Beckenham, Richard William Brogden, M.B.Lond., formerly of Tockwith, Yorkshire, to Constance Mary, younger daughter of John George Rhodes, of Beckenham.

GOSSE—SMITH.—On the 6th inst., at St. Thomas's Church, Salisbury, by the Rev. Canon Morrice, assisted by the Rev. Robert Wilkes Gosse (brother of the bridegroom), Hope Wilkes Gosse, M.R.C.S. & L.R.C.P., of Eccleshall, Stafford, to Mary, third daughter of George Smith, Solicitor, Salisbury.

SMART—JONES-GIBB.—On the 12th inst., at Holy Trinity Church, Paddington, Francis Gray Smart, M.A., M.B., of Tunbridge-Wells, to Marion Pender, widow of T. Jones-Gibb, of Bredbury, Tunbridge-Wells.

SWAIN—HEXT.—On the 6th inst., at All Saints', Plymouth, W. P. Swain, F.R.C.S., to Lucy, youngest daughter of the late Rev. John H. Hext.

DEATHS.

BURROWS.—On the 1st inst., at The Limes, Crediton, Devon, Edmond Boulter Burrows, Surgeon-Major, Bombay Army, retired, youngest son of the late Rev. W. F. Burrows, Vicar of Christchurch, Hants, aged 53.

JEAFFRESON.—On the 12th inst., at Pomfret House, Highbury New-park, John B. Jeaffreson, M.R.C.S., L.S.A.Lond., aged 48.

MACDONOGH.—On the 9th inst., at 15, Clapham-park-road, S.W., John MacDonogh, M.R.C.S.E. & L.S.A.Lond., aged 86.

MILROY.—On the 11th inst., at Church-road, Richmond, Surrey, Gavin Milroy, M.D., in his 81st year.

ROWE.—On the 9th inst., at Wimborne, Dorset, Charles Reynolds Rowe, F.R.C.S., aged 72.

SHEA.—On the 7th inst., at Crescent Lodge, Kingston-hill, Surrey, John Shea, M.D., in his 85th year.

STARKEY.—On the 5th inst., Charles Starkey, of Upper Wick, Worcester (formerly of West Bromwich, Staffordshire), M.R.C.S., in his 83rd year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, January 18.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M. Also on Thursdays at 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF ARTS.—8 P.M. Prof. H. S. Hele Shaw: Friction (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Jonathan Hutchinson, F.R.S.: Some Moot Points in the Natural History of Syphilis (Lettsomian Lecture).

Tuesday, January 19.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. Robert Stawell Ball: The Astronomical Theory of the Great Ice Age.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Eve: (1) Examples of Colloid Degeneration of Breast and Omentum; (2) Dislocation of Hip of a Cow (card); (3) (for Mr. A. Lingard) Specimens of Actinomycosis in Oxen (card).—Dr. S. West: Ulcers of Gall-bladder, with Pus in Portal Veins.—Mr. Sydney Jones: Spontaneous Fracture of Urinary Calculi.—Mr. Clutton: Spontaneous Fracture of Urinary Calculi (card).—Dr. Ashby: Diffuse Sclerosis of Brain in a Child of eighteen months.—Dr. A. Davidson: Malignant Growth (secondary to cancer of pylorus) obstructing Thoracic Duct and invading Minute Lymphatics of Lung.—Mr. Barwell: Two cases of Aneurysm.—Mr. Churchill: (1) Post-nasal Fibroma in a Child; (2) Syphilitic (congenital) Necrosis of Vomer.—Mr. Cripps: Stricture of Rectum.—Mr. Bruce Clarke: Rectum after Colotomy.—Dr. Goodhart (for Dr. Marshall): Calculus in Bladder of Female Child of two years (card).—Dr. Carrington: Cancer of Body of Stomach.—Mr. J. B. Sutton: Congenital Inguinal Hernia in a Monkey (card).—Mr. H. Fenwick: Tumour of Bladder (card).—Dr. Hadden: (1) Intestine in Lymphadenoma (card); (2) Lipæmic Blood in Diabetes (card); (3) Mucous Cyst of Tongue (card); (4) Gumma pressing on Ureter (card).

Wednesday, January 20.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

TRANSFER OF PRACTICES.

Medicus complains that a short time back he observed an advertisement in THE LANCET headed "Practice Wanted." He replied, and sent full particulars of his practice, also name and address, thinking it was inserted by a private practitioner. He found, however, to his astonishment, that it had been inserted by a medical agent, who was now in possession of the details of the practice and of the movements of our correspondent, who thinks it a most unfair mode of procedure on the part of any agent. A similar complaint has reached us from another correspondent.

Mr. F. C. Banks.—We cannot devote more space to the subject at present.

T. H. is referred to an annotation in our last issue, page 79.

ARTIFICIAL TEETH.

To the Editor of THE LANCET.

SIR,—The warning repeated in your issue of Jan. 9th, as to the danger, to say nothing of the want of cleanliness, of retiring to rest at night without removing artificial teeth, will, I trust, have some beneficial effect. For some time I have been impressed with the carelessness of people on this subject, and many are inclined to treat with scant respect any opinion expressed as to the desirability of nightly removal. Only a day or two since, when searching for dental irritation as a possible cause of an obstinate eye trouble, in answer to my question whether she removed her artificial teeth, the patient answered readily, "Yes"; but I found she only did so once or twice a month. Are dentists as careful in giving directions as to the withdrawal every night of artificial teeth as they should be? My experience would lead me to answer in the negative. Some practitioners have, on the other hand, I believe, desired their not frequent removal. Certainly, directions should be as precise—or *more so*, on account of the danger—as the surgeon gives respecting the use of an artificial eye. I am, Sir, yours faithfully,

Sheffield, Jan. 11th, 1886. SIMEON SNELL.

SEPARATE EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—In reply to "An Anxious Parent and a F.R.C.S.," in your issue of this day's date, I beg to state that his son may pass any one or more of the subjects which he still requires to complete his preliminary at the Universities of Edinburgh or Glasgow and the Royal College of Physicians, Edinburgh, or the Faculty of Physicians and Surgeons, Glasgow. The charge at these boards is £1 for all or one subject, except at the University of Glasgow, where it is 10s. The secretaries of these institutions will forward him full particulars as to dates, &c., on application. I am, Sir, your obedient servant,

Jan. 9th, 1886. WM. M. D. G.

HELEN PRIDEAUX MEMORIAL FUND.

IT is proposed to raise a sum in memory of Miss F. Helen Prideaux, M.B. & B.S. Lond., sufficient to endow a prize or scholarship bearing her name. The following contributions to the fund have been received from members of the medical profession:—

Dr. Garrett Anderson. ...	£25	0	0	Dr. Tempest Anderson ...	£1	1	0
Sir Wm. Gull, Bt., F.R.S.	10	10	0	Mrs. Atkins, M.D. ...	1	1	0
Dr. Clifford Allbutt, F.R.S.	10	10	0	Miss Barker, M.D. ...	1	1	0
Stanley Boyd, Esq. ...	5	5	0	Dr. Thomas Barlow ...	1	1	0
Dr. W. Allen Sturge ...	5	5	0	Dr. Elizabeth Blackwell ...	1	1	0
Prof. Schäfer, F.R.S. ...	5	0	0	Miss Boddy, L.K.Q.C.P.I.	1	1	0
Dr. and Mrs. Waller ...	5	0	0	Thomas Bond, Esq. ...	1	1	0
Dr. Ford Anderson ...	2	2	0	Harrison Cripps, Esq. ...	1	1	0
Dr. G. W. Balfour ...	2	2	0	Dr. Curnow...	1	1	0
Prof. Bentley	2	2	0	Miss Walker Dunbar, M.D.	1	1	0
Dr. Cheadle	2	2	0	Dr. A. T. Myers	1	1	0
Dr. Matthews Duncan ...	2	2	0	Mrs. Burdon Sanderson ...	1	1	0
C. W. Heaton, Esq. ...	2	2	0	Miss Edith Shove, M.B.Lon.	1	1	0
Sir Jas. Paget, Bt., F.R.S.	2	2	0				
Dr. Octavius Sturges ...	2	2	0		£252	9	0

Subscriptions may be sent to Mrs. Garrett Anderson, M.D., 4, Upper Berkeley-street, or to the London and Westminster Bank, Stratford-place, W.

Unqualified.—The question is legal rather than medical; but our correspondent is entitled at least to be paid up to the time of his leaving.

PEMPHIGUS (CONTAGIOSA?).

To the Editor of THE LANCET.

SIR,—While attending a patient after her confinement in October last, I was asked on the sixth day to look at the baby, who had an eruption on the skin. The child, a healthy male infant, was the last of a family of six, all living, the eldest being seven years and a half old. I found it had a few small patches of hyperæmia about the nose and face, and on the fingers of each hand. On the fingers also were one or two bullæ filled with clear fluid. During the next three or four days the hyperæmic spots became bullous, those already bullous became more tense, their contents thicker, and finally burst, leaving behind a raw surface similar to that of a burn after the blister has been removed. This condition spread—the bullæ seeming to run together in places—till the face was raw over about half its surface, while a similar condition existed on all the fingers and thumbs, and parts of the feet and thighs. The only treatment adopted was zinc oxide in the form of lotion, ointment and powder, outwardly applied. The child never seemed at all affected in its health, taking its food well, its motions being of good character, and its rest but little disturbed. In from a fortnight to three weeks it had fairly recovered.

So far, I have traced the one case only, because it was the first to appear, because it was the most severe, and because its description cannot leave any doubt behind. All must agree that it was a case of pemphigus; but the curious part of the history is that similar bullæ appeared on four of the five other children, the father, and the monthly nurse. All with one exception were very slightly affected; in all, the fingers were chiefly attacked, and all began and ended under the same treatment, in a manner similar to that already described.

I failed to find the least cause for the outbreak. The infant was from the first brought up by hand, but its excellent health and perfectly normal excretions seem to show plainly that there was no fault in the food. I am sure there was no congenital cause, the family history being free from the faintest suspicion of taint. And why did it run through the house? Does not this look like contagion? The children were frequently in their mother's room, and no doubt often kissed the baby, as children will. The father was of course often playing with his children when at home, and the nurse too found her chief work in looking after, and attending to the infant. It is very easy to understand therefore, on the theory of contagion, that all who did should have caught the complaint. It is very difficult to find any other reason that will satisfactorily account for it. Still it is far from my wish to say that because difficult to find, therefore no other cause could have existed. I only regard the communication as a curious and rare piece of evidence in favour of the existence of a contagious form of pemphigus; and its curiosity and interest must be my excuse for wishing to obtrude myself on your valuable space.—I am, Sir, yours faithfully,

Beckenham, Kent, Jan. 9th, 1886. FRANK STURGES, L.R.C.P.Lond.

M.B. had better apply to the Director-General of the Navy Medical Department for an authoritative statement on the matter.

"DISPENSING PRACTITIONERS."

To the Editor of THE LANCET.

SIR,—Having read an exposition on the above subject in your issue of the 9th inst. (page 83), I should like to say that as a householder keeping up an ordinary country house establishment, four miles from a town, I find it a great convenience that after his visit to a case of no particular urgency the "doctor" should say at what hour the medicine will be ready at his house, instead of being obliged—solely, so far as it appears to me, to please the dispensing practitioners' detractors—to send a messenger with a prescription to a druggist, involving more or less time to wait, whereby is held out the temptation to dawdle or drink. This would be obviated to a great extent by the former convenient arrangement.

I am, Sir, yours obediently,

Chevet, Jan. 11th, 1886. LIONEL M. SWINNERTON PILKINGTON.

BATH CHAIRS AT HASTINGS AND ST. LEONARDS.

A CORRESPONDENT in whose veracity we can place reliance writes to warn medical men against sending any of their patients suffering from nervous or spinal complaints to St. Leonards and Hastings without first obtaining, what is very grudgingly accorded, a written permission from the superintendent of police to have their chairs drawn along the pavements, instead of the uneven roadway. It is very reasonable that the municipality should instruct the police not to allow Bath chairs to indiscriminately use the pavement; but it will scarcely be believed, though it is nevertheless strictly true, that the municipality, disregarding the petition signed by nearly all the medical men in Hastings and St. Leonards, decline to allow patients, though armed with a certificate from one of them, to be drawn along the pavement, even to get to and from their houses and the promenade by the sea.

Mr. M. G. Biggs.—The institution at West Hill, Putney, or that in the Clapham-road, would probably be suitable for the case.

CASE OF PLACENTA PRÆVIA.

To the Editor of THE LANCET.

SIR,—Having read in your issue of Dec. 19th a letter from Mr. O'Bryen recording a case of partial placenta prævia, in which he states it would be interesting to know the method of treatment adopted by various practitioners, I thought the following case might be of interest.

Last September (Sunday, 6th) I was summoned to Mrs. C—— (living three miles from the house in which I was resident), who, the messenger stated, was "flooding fearfully." On arrival I learnt that the woman was a multipara, and was now about seven months and a half pregnant. On entering her room I found her lying on the bed in the usual obstetric position, and saw that her face and arms were extremely blanched, great drops of sweat stood on her brow, and she had that peculiar dead-blue appearance showing an advanced stage of hæmorrhage. The pulse was small, quick, and compressible. On examination, the vagina was found to be blocked with clots, and it was easy to see that the clothes upon which she was lying were saturated with blood. Having cleared out the clots, I found the os soft, dilatable, and about the size of a five-shilling piece; the dilated space was occupied by a soft roughish tenacious mass, easily recognised as placenta; so, insinuating my fingers, I stripped up the placenta as far as I could reach all round, with the double object of stopping the bleeding and ascertaining where there was least thickness, but as on all sides nothing but placenta could be felt, I thought the case was probably one of entire placental presentation. Not being able to get my hand through the os, and the hæmorrhage having ceased, the cessation being due no doubt not only to the clearing of the lower placental zone, but also to the patient's collapsed condition, I turned my attention to her general condition, and administered hypodermics of ether, and several teaspoonfuls of brandy and ergot by mouth. The examination having caused some considerable pain, and there being now some uterine action, I asked permission to give chloroform and deliver at all hazards, as it was imperative to complete delivery before the hæmorrhage recommenced, for had it done so, it must have proved fatal. When the patient was sufficiently under the anæsthetic, I passed my hand into the vagina, and with my fingers rapidly dilated the os, and again searched for a thin spot, but could find none. I therefore scraped my way through the placenta, found a head presenting, ruptured the membranes, turned and delivered; the placenta and membranes followed within five minutes of the birth of the child, the uterus contracted well, and the woman, although for some hours in a most critical condition, under repeated injections of ether, the application of warmth, with friction, recovered from her extreme collapse, and made a good recovery.

On examining the placenta and membranes, I found the latter intact except where the hand had passed first through the placenta, and then through them, and that my hand had as nearly as possible gone through the exact centre of the placenta. As these cases of entire placenta presentation are extremely rare, much more so than partial, it seemed to me worthy of note, as well as my mode of treatment. First, the stripping of the lower placental zone according to the teaching of Dr. Barnes is the most essential point, for not only is the hæmorrhage thus stopped, but time is also gained. Secondly, many would advocate bimanual turning as incurring less risk of further hæmorrhage, and also because it avoids the introduction of the hand into the uterus. Others again would say that having found a head presentation, and ruptured the membranes, forceps ought to have been applied.

My reasons for not following the above plans of treatment were, that personally I find bimanual turning much easier in theory than in practice. To apply forceps to a head above the brim through a jagged placenta is a difficult and tedious mode of delivery. The course I adopted recommends itself by the fact that one has at once entire control of the labour, and can hasten delivery as much as is thought requisite, not to mention the body acting as a plug.

I do not think that with a dilatable os and membranes intact the introduction of the hand is a hazardous proceeding; moreover, it is much more rapid than any other method, and with the advantage of anæsthesia, one need have no dread of the "shock," that bug-bear of many practitioners.—I remain, Sir, yours obediently,

ERNEST E. KING,
Late Resident Obstetric Physician, Middlesex Hospital, and
Dec., 1885. Assistant Medical Officer, Cleveland-street Asylum.

CONSTIPATION.

Mr. Geo. Smith, M.R.C.S., of Stratford, Ontario, writes to us to confirm statements made in our columns as to the benefit to be derived in some cases, especially those in which constipation is a prominent symptom, from drinking largely of fluids. Mr. Smith mentions an instance in which a female patient whose bowels had not been moved for three weeks, in spite of the exhibition of castor oil, salts, and other cathartics, was permanently relieved of the constipation by copious draughts of weak tea.

Dr. Weljaminow (St. Petersburg).—We cannot exchange.

Dr. Bell Taylor.—As early as possible.

THE APPEAL TO CANADIAN PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—Allow me to thank you for your suggestion. I had already quoted from Dr. Buchanan's report, and had been jeered at for bringing forward what the anti-vaccinationists call "interested evidence." May I ask you to insert these latest statements, with the hope that some kind brother will be able to explain the truth concerning them.

Prof. Coderre, physician to the Hôtel Dieu Hospital, Montreal, is stated by a correspondent to the *Banbury Guardian* to give the following as facts collected by himself during the present small-pox epidemic:—"M. Z. Lapierre, 33, Desalabeurry-street, had a child die of small-pox soon after it was vaccinated. By his physician's advice his four remaining children were vaccinated: all took the small-pox and died. Pierre Mainville, 172, Drolet-street, had his child, one year old, vaccinated; it died fifteen days after, in consequence of vaccination. The Hon. Judge Dr. Montigny had his children vaccinated in September; one, a little girl, took small-pox, and is dangerously ill. The child of Louis Beloc, 267, Papineau-road, was vaccinated, and died a few days after in consequence of it. The child of Joseph Grenier, 101, Dufresne-street, was vaccinated, and took small-pox eight days after vaccination. M. Marios, 154, Plessis-street, had two children vaccinated; both took small-pox, and one died. From St. Camille Hospital the report is for one week (Nov. 1st to 7th). 'There are now in this hospital 198 small-pox patients; of these, ninety-four are vaccinated. Amongst the dead are twelve who were vaccinated, and three who had small-pox the second time.'"

Of course we can explain the above by supposing that the vaccinations were badly performed; and then, again, the fourteen days' incubation renders it possible for the vaccine to have been inserted while the small-pox virus was in the system. You will probably have seen these statements already in the anti-vaccination organs and pamphlets, for doubtless you are inundated with these missives, and agree with me that if we can have evidence to refute their mis-statements the uninitiated will not be so easily misled.

I am, Sir, yours obediently,

G. COCKBURN SMITH, M.D.

Middleton Cheney, Banbury, Jan. 11th, 1886.

HOSPITAL ABUSE.

F. L.—We do not see why such a patient should not be under the care of a general practitioner. If the case prove impracticable or incurable, a reference to a hospital physician or surgeon from him would always secure consideration.

Mr. R. C. Bennett (Trinidad).—The paper has not come to hand.

Prof. Schiller (Berlin).—The book has been received.

"WINTER COMFORTS FOR MEDICAL MEN."

To the Editor of THE LANCET.

SIR,—I know well the "Jemimas" Mr. Pridgin Teale speaks of (THE LANCET, Jan. 2nd, p. 38), and twenty or thirty years ago, whatever may be the case now, they were commonly worn in the midland and northern counties in snowy weather. When we have had snow in former winters, I have tried in vain to get them in London, and since reading Mr. Teale's letter have tried again at Cording's and other indiarubber shops, but still without success. I find a sort of extended, flannel-lined golosh generally kept; but this is a totally different thing from the snow boot in question, which is made entirely of felt. If Mr. Teale would let his *confrères* know in your columns where the real thing can be obtained, he will doubtless be doing them service, as well as conferring a favour upon, Sir, Your obedient servant,

Jan. 9th, 1886. ONE OF YOUR NON-PROFESSIONAL READERS.

H. A. B.—1. The Home Secretary.—2. Our advertising columns contain the information.

HYPERIDROSIS.

To the Editor of THE LANCET.

SIR,—Will any of your readers suggest a remedy for the above annoying symptom? The patient who suffers from it is over fifty years of age, and is of a highly nervous temperament. The least undue amount of exercise invariably causes him to perspire most freely, especially on the head and face. He has tried almost everything, both as regards local applications and general treatment, but has found nothing even partially relieve, except small doses of atropine combined with oxide of zinc. He has worried so much on account of this that he frequently suffers from profound melancholia.—I am, Sir, yours faithfully,

Jan. 11th, 1886. ENQUIRENS.

THE INSURANCE RAILWAY GUIDE.

THE example of a weekly contemporary—*Tit-Bits*—in holding out as a bait to purchasers the boon of insurance against fatal railway accidents, provided that that paper for the week in which the injury is received is found upon the person of the victim, has been followed by the publishers of the Insurance Railway Guide. The purchase of a sixpenny Guide provides for the payment of £200 in case of the purchaser's death during the month for which the guide is issued; and the purchase of a shilling guide provides for the payment of £500 in case of death, and £2 per week for total disablement. The venture ought to be well supported by commercial travellers and others who travel much by rail.

An Anxious Parent will find his question answered in another column.

J. B. T.—Barraud, 96, Gloucester-place, Regent's-park.

THE END OF A WALKING-STICK EMBEDDED IN THE FACE FOR TWO MONTHS.

To the Editor of THE LANCET.

SIR,—The following case may be sufficiently interesting to be reported in your columns.

On Sept. 29th a patient presented himself, complaining that "a piece of bone was growing from his face," and seeking advice about it. He stated that one evening, eight weeks previously, he was very drunk, and that whilst going home he recollects quarrelling with somebody in the street, and "thinks" he received a blow on his face during the altercation. Upon the following day he felt pain in the left side of his face, and noticed a small wound under his left eye. A painful spot, or "boil" as he termed it, arose in the position of this small wound, and after a few days burst, liberating a large amount of pus; since then fetid matter has continued to discharge from the wound; and three weeks since he first noticed a small, hard, pointed body in the wound, which body he called "the bone." Situated immediately under the anterior part of the left malar bone, one inch from the orifice of the left nostril, was to be seen a hole half an inch in diameter, and projecting from it was a pointed substance, which, on close examination, appeared to be wood. This projection was seized with a pair of forceps, and the end of a walking-stick, with ferrule attached, measuring two inches in length, was withdrawn. The resulting cavity healed rapidly by granulation, and by Oct. 12th was quite filled.

I am, Sir, yours obediently,

SYDNEY H. A. STEPHENSON, M.B.,

Oct. 24th, 1885. Resident Medical Officer, Rochdale Infirmary.

MAHOMED MEMORIAL FUND.

Dr. A. H. Watson.—Henry Rutherfurd, Esq., Barrister-at-Law, 2, Harcourt-buildings, Middle Temple, E.C.

TREATMENT OF A SPLIT FINGER-NAIL.

To the Editor of THE LANCET.

SIR,—I should be glad if some of your correspondents would suggest some treatment in the following case.

The nail of my right index-finger has split down the middle; it has been in that state for five years. I cannot get it to grow; it constantly seems as if it would do so, but never gets further than one-eighth of an inch from the root. It is the finger I use most in examining the os uteri in midwifery cases. Possibly some syphilitic virus may have been the origin; but I never had syphilis or any constitutional symptoms of it. I have scraped the nail very thin and applied nitrate of silver, but all to no effect. It renders the finger unsightly. I should be averse to evulsion of the nail. I am, Sir, yours truly,

January 11th, 1886. RUS.

Dr. Markley (Juniata).—We have no knowledge of such an institution.

D. H. B.—Professor Liveing, Cambridge.

THE TELEPHONE AND MEDICAL TOUTING.

To the Editor of THE LANCET.

SIR,—I was surprised to see in a chemist's shop in a first-class watering-place on the south coast a large placard, stating: "Dr. A—— can be communicated with from here by telephone." There was another doctor in practice nearly opposite the shop. The telephone man, I found out, resided a little more than a quarter of a mile away; therefore the object was plain. Is not this, with all the interested recommendations of the chemist as to Dr. A—— being the best doctor, &c., very unprofessional?

I am, Sir, yours obediently,

Jan. 6th, 1886. SURGEON.

*** We quite agree with our correspondent.—ED. L.

INFANTILE HERNIA.

To the Editor of THE LANCET.

SIR,—I should feel obliged if any of your readers could tell me the most satisfactory treatment to adopt in cases of congenital hernia, which are constantly brought under one's notice, when the children are a month or two old. I am, Sir, yours faithfully,

Jan. 12th, 1886. ENQUIRENS.

Digitized by Google

VACCINATION IN JAPAN.

THE Japanese do not appear to have lost any of their faith in the efficacy of vaccination for small-pox. It is announced that they have just enacted a very stringent law on the subject, which, besides ordinary vaccination in the first year of infancy, provides for at least two subsequent revaccinations at intervals of from five to seven years, so that by the time a child has reached its fifteenth year, it will have been vaccinated three times. In addition to this, during epidemics of small-pox, local authorities have power, when they deem it necessary, to order the vaccination of all the inhabitants of their districts, irrespective of the vaccination required by the law.

Dr. George Mundie.—The method of fire-lighting suggested by our correspondent has been often described and advocated.

PARALYSIS AGITANS.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "Inquirer," who asks in your last issue for some hints on the treatment of paralysis agitans, I beg to suggest that electricity (constant current) should be used; likewise sulphur baths, which are certainly of very great value and importance in the disease. Good may be done by keeping the brain quiet by hyoscyamus, to which, I think, conium and gelseminum should be added, to quiet the nervous irritation at both central and peripheral extremities. The latter drugs should, however, be carefully watched, and, if any unpleasant symptom ensue, should be discontinued at once. The hyoscyamus may be used for an indefinite period with great advantage; also iodide of potassium, to cause as much absorption of matter as may be, preferably combining the latter drug with iron. In the use of electricity good results have been obtained by placing the positive pole over the spine, and drawing the negative along the course of the nerves as they leave the vertebral column to the periphery. I should, however, strongly urge and advise the use of sulphur baths. I shall be glad to hear the result of this treatment in "Inquirer's" case.

I am, Sir, yours faithfully,

Jan. 12th, 1886. T. J. LAVERS, M.D.

DYSMENORRHŒA.

To the Editor of THE LANCET.

SIR,—I have found the aromatic spirits of ammonia in drachm doses a thoroughly trustworthy remedy for dysmenorrhœa. It should be given every hour or two, according to the requirements of the case, but one dose every four hours is generally enough. In place of the alcoholic stimulants generally prescribed, I think this remedy deserves recommendation.

I am, Sir, yours truly,

Jan. 8th, 1886. C. R. ILLINGWORTH, M.D.

THE ALBO-CARBON LIGHT.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me whether the albo-carbon light has been found to exercise an irritating influence on the throat or the organs of respiration?—I am, Sir, yours faithfully,

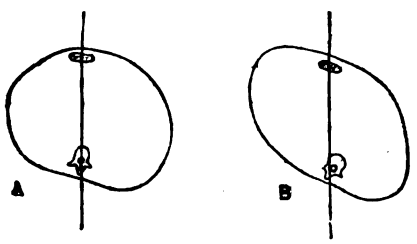
Lectures

ON THE

SURGICAL TREATMENT OF EMPYEMA.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.



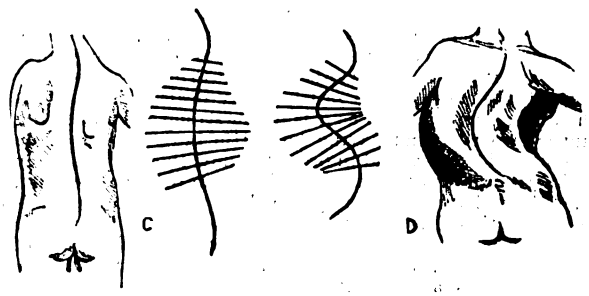
BY RICKMAN J. GODLEE, M.S., F.R.C.S.,

SURGEON TO THE HOSPITAL, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.

GENTLEMEN,—In the last lecture we were engaged in discussing some points in the treatment of recent cases of empyema. We have now to consider what can be done for the cure of a case which has become chronic, and in which the efforts of nature to close the cavity have been brought to a standstill. Such cases are more common amongst adults than children for obvious reasons, and may be classified under three headings: (1) Those in which a mere sinus remains, surrounded by dense fibrous walls; (2) those in which a large cavity exists, the lung being more or less completely collapsed, the diaphragm having been drawn up to the utmost possible extent, and the structures in the mediastinum and the opposite side of the chest having come over to the diseased side as much as possible, but the chest wall having fallen in only to a very slight extent; and

FIG. 1.



Cyrtometric tracings at about the level of the nipple.
A, A case of empyema. B, A case of lateral curvature.

(3) those in which the chest wall has fallen in to a considerable extent, producing often great deformity, but leaving a cavity which cannot close. In all of these cases the pleura becomes remarkably thickened, forming a dense layer of hard fibrous tissue, reaching at times an inch or more in thickness. The deformity of the chest which is produced follows from the fact that the ribs are drawn close together like the segments of a closed fan; the result of this is a lateral curvature of the dorsal spine, the concavity being directed towards the affected side. A consequence of this, again, is the separation of the ribs on the sound side, like the segments of a fan that has been opened, and thus a deformity is produced somewhat like that which occurs in ordinary cases of scoliosis. The angles of the ribs on the affected side become flattened out, while those on the sound side become more acute, and there is a corresponding flattening in front on the sound side; but there is not, as in ordinary lateral curvature, as a rule, any increased angularity on the affected side near the junctions of the ribs and cartilages. On the contrary, the diseased side is flattened both in front and behind, as may be seen from the accompanying cyrtometric tracings of the two conditions (Fig. 1, A B). The diagrams (Fig 2, C D) illustrate the difference in the nature of the curve which obtains; for while after an empyema the dorsal curve is very long, and occupies the whole dorsal region, in scoliosis we generally find a compensatory curve beginning at the lower part of the back, and thus, while in the former case all the ribs are separated, in the latter some are separated and others approximated. The prominence of the angles, together with the separation of the ribs on the sound side, causes an elevation of the shoulder and a prominence of the scapula, giving a humped appearance to the back, which becomes more and more mesial in position as the disproportion between the two sides becomes more and more marked, so that in an exaggerated case, when the clothes are on, it comes to have an outward resemblance to that produced by an angular curvature in the dorsal region. The compensatory curves in the lumbar and cervical regions are shorter than those of ordinary lateral curvature, and there is much less rotation of the bodies of the vertebræ, so that the curve indicated by the line of the spines corresponds more nearly with the actual curve of the bodies than is the case in the latter condition. The net result is that the affected side has a much smaller capacity than before, while the sound side is larger, and can thus accommodate the working lung, the size of which is increased by compensatory hypertrophy. In the most exaggerated cases there is occasionally a very acute prominence parallel with the sternum, near the junction of the ribs and their cartilages. The size of the cavity, provided there be a free outlet, determines the amount of discharge, and this again determines the amount of the constitutional disturbance from which the patient will suffer. What these disturbances are, and what the prospect for the patient is if left alone, must next be considered.

A patient with a small cavity and a pretty free opening may go on for a long time—i.e., for a considerable number of years—without any very serious symptoms manifesting themselves. The oldest case of empyema of which I have any notes is that of a man upon whom I operated at Charing-cross Hospital when I was assistant-surgeon there in the year 1876. He was then not much over twenty years of age; he had a good family history, and showed no signs of tubercular disease. If it is possible under any circumstances to trace the cause of this disease to an injury, this seemed to be a case in point. At all events, his illness

FIG. 2.

The above illustrates the difference between the curve of the spine and the deformity in the ribs in—C, a case of empyema; D, a case of lateral curvature. The schemes of the arrangement of the ribs are purely diagrammatic; the drawings of the backs are from actual cases.

appeared to depend upon the fall of a load of gravel on to his back some time previously, but it is not clear that he sustained a fracture of his ribs. When he came under notice he had his right chest full of fluid, which had made its way through the chest walls, so that he had a large collection of matter in the soft parts at the lower and posterior part of his axilla. After opening this the finger was passed into the cavity, and, being used as a guide, an incision was made in about the eighth or ninth space, and drainage-tubes were inserted. The case pursued a pretty favourable course. The antiseptic dressings employed at first were ultimately given up, and the cavity became much reduced in size, so that it would contain at last not more than an ounce. He had a small necrosis of one of the ribs, which separated, and after the employment of a variety of tubes and the use of injections, &c., he at last settled down to wear a piece of a No. 12 English gum-elastic catheter, which he has continued to do ever since. I have kept this man constantly under observation, for he now attends at University College Hospital, and though at times he suffers from a slight accumulation when the tube becomes blocked, he has continued to lead an active life as a costermonger, not feeling, however, strong enough to resume his original occupation as a navvy. He stoutly refuses to submit to any other operation. Well; for years this man showed no signs of suffering from the prolonged discharge; his muscular development was good, and his health also quite satisfactory; but of late years he has slowly and steadily began to show signs of albuminoid

Digitized by Google

degeneration. His skin is now more sallow than it was, his liver can be felt and is enlarged, and his fingers are clubbed, but it is impossible to say that he may not have several more years of active life before him. Cases of this kind must be borne in mind in advising a patient to undergo the somewhat formidable, though I believe not really dangerous, operation I shall presently describe.

This may be taken as typical of a considerable class of cases, and I could easily mention others in point from amongst our own patients. But in most of them the discharge comparatively soon produces marked changes: the great clubbing of the fingers, and, in some cases, similar swellings about the wrists, ankles, and the nose, the characteristic pale and earthy colour of the skin, the emaciation, and, lastly, the albuminoid changes, with albuminuria, indigestion, and diarrhœa, which we are in this hospital very apt to associate with the word empyema. A very grave prognosis must therefore always be given in cases of empyema which will not heal, and the question arises as to what, if anything, can be done for their relief. In the first place, a thoroughly free drainage must be obtained either by dilating the original opening or by supplementing it with another in a more favourable position. A second opening alone has often proved sufficient to enable the cavity to close, simply by affording a free exit for discharge; but it does not yet appear that a simple enlargement of the original sinus might not have been sufficient for this purpose. This second opening will often be best made at a higher level than the primary one, for this reason:—it is, as might have been supposed *à priori*, almost invariably the case, that the lower part of the chest cavity is the first to close. This arises partly from the fact that there is only a small space between the diaphragm and the thoracic wall, partly because the structures in the mediastinum can more readily be drawn over in the lower and middle parts of the chest, and partly because the ribs, being larger, can yield more easily, and so assume the modified shape and position that the altered circumstances require. This, as was before stated, is one of the reasons why a very low opening is in most cases to be deprecated, and it will be afterwards seen that in old cases the lower part of the chest can be satisfactorily dealt with, but that the upper part, enclosed as it is by the strong and unyielding upper two ribs, and having but little lung substance on the other side to expand in order to allow the comparatively rigid structures in the upper mediastinum to come over, and, moreover, having probably no lung of its own available, as this has usually sunk down and back near the spine, soon reaches the extreme possible limit of contraction, and, when granulation has done all that it can, often remains as a cavity which defies all that surgery can devise for its closure. The second opening may be made then at any available part, not too far down, and best at a considerable distance from the original one. It is the simplest thing that can be done for an obstinate case, and I have several times seen it successful. But there are many cases in which it is obviously impossible that this should lead to a cure—viz., those in which, although there is a free opening and no accumulation of discharge, there remains a cavity of considerable size. If we suppose a case in which the various walls of this cavity have been drawn in to the utmost possible extent, there is nothing further to trust to, if things be left alone, than the filling in of the cavity by granulations. Now, when this has gone on to a certain extent a degree of tension is established, which effectually prevents a continuation of the process. A state is then reached in which the pleura becomes lined with a perfectly smooth surface—secreting pus indeed, but showing no signs of developing fresh granulations. This is quite analogous to what we see in an ordinary callous ulcer. Here the intense hardness of the surrounding parts establishes a high degree of tension, and therefore the contraction which is essential to the healing process can no longer take place. The result is an ulcer with a hollow base, covered by minute granulations—if they are worthy of the name—of low vitality, and disposed to slough at any slight irritation, rather than to the development of fresh material. In these cases the one essential of treatment is to diminish the tension, which may be accomplished either, as has been often done, by making a circular incision round the ulcer, or by putting the patient to bed and so reducing the chronic œdema, or by applying a blister to the surface of the sore, or by placing an elastic bandage on the limb. To get over the difficulty in the case of the chest, it has been suggested to apply sponge-grafting; that is, to diminish the size of the cavity by filling it with a new material—viz., an organic basis,—which becomes vivified by the migration into it of young cells from the surrounding parts; and it has apparently proved successful in certain circumstances. I have not met with a suitable case to put this in practice. It is essential that the cavity should be in an aseptic condition, which is rare in old cases of empyema. If it be septic, the pieces of sponge introduced soon become putrid, and then not only is it impossible for new cells to find their way into the mass, but this becomes a source of increased irritation to the pleura and of danger to the patient. This was the case in the only patient in whom I tried it, J. H. (Case 4, Table II.). Many pieces of sponge were introduced at different times, but at a subsequent operation they were found unaltered in size, but smelling horribly. To be successful, then, the cavity if septic must first be purified, and then small pieces of sponge, previously decalcified by soaking in a weak solution of nitric acid, must be pushed up to the end of the cavity, and when they are found to adhere to the wall others may be introduced on a subsequent occasion. But it is clear that this method of treatment cannot be of very wide application. To imitate, then, the treatment we apply to a callous ulcer, the only available plan is to diminish the resistance of the chest walls. It was this idea which first led the late Professor J. A. Estlander of Helsingfors to suggest the removal of a considerable length of a variable number of ribs, a suggestion which he first appears to have put in practice in 1877.[1] His patient was twenty-one years old, and the empyema had been opened, apparently not very satisfactorily, eight months previously. He removed 4 centim. of the seventh, 3 centim. of the sixth, and 3 centim. of the fifth ribs through an oblique incision passing upwards and outwards from the fistula. By June 25th of the same year the sinus had completely closed. This was the starting-point of an operation which has been very much practised of late years; which has been much vaunted by some and equally decried by others; which has, I am sure, great merits; but which, because too much has been claimed for it, has often led to disappointment. I will quote, before commencing a description of the operation, a few words from the second of his two articles referred to below to explain his exact position as regards it:—

"It might perhaps be concluded from my article [the first referred to] that, in order to obtain a cure, it is always sufficient to resect once for all from 3 to 6 centim. of several ribs. But this is not what I intended to imply, and is not consistent with the fact. When it is necessary to operate upon a case of chronic empyema, the first essential condition is for the operator to make himself acquainted with the extent of the cavity in all directions. I have been in the habit of using a male urethral bougie, but possibly other instruments may answer the purpose better. After ascertaining the size of the cavity, and in which direction it is most extensive, the operation must be planned upon these data—that is, the largest portion of ribs must be removed at that part where the lung is furthest removed from the thoracic wall. Thus it is not an operation which, when once it has been described, can be repeated exactly; but, on the other hand, the exact steps must depend upon the peculiarities of each individual case; and, as the shape of the chest must be in different cases differently modified, the name of 'thoracoplasty' might well be given to the operation. Nor, again, is it enough, as might be gathered from the cases which were quoted, to do the operation once only. A larger experience has shown me that there are cases where the cavity, after diminishing rapidly as the result of the operation at first, and afterwards more slowly, reaches at last such a stationary condition that no progress is noticed even in the course of months. Under these circumstances the cavity must be again explored and the operation repeated; there may, indeed, be some cases in which even a third operation is necessary. Generally in these secondary operations, which have to be done through the old scars, it is enough to remove a smaller number of ribs, but the portions removed should be at least as long as before."

I can fully endorse these remarks of Professor Estlander, but am not sure that in adults I have yet removed sufficiently long portions of bone to meet the instructions he has laid down. I have never employed it in an adult where a really large cavity remained, because all the patients

[1] Revue Mensuelle de Médecine et de Chirurgie, 1879, pp. 157, 885.

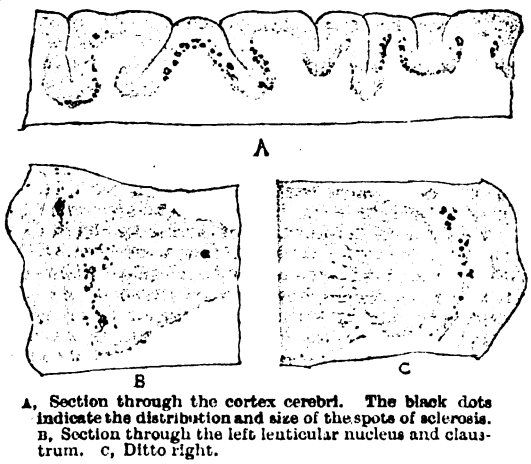
Digitized by Google

in whom this condition was found presented other symptoms which seemed to render the operation inadvisable. I have, however, removed considerable portions of ribs in adults who had only a small cavity, and also in children with much contracted chests, but a pretty large remnant of the originally completely distended pleura. In all, great benefit has been derived, the cavity and the discharge being much diminished; but I am not sure that I can bring a single instance where a complete closure of the cavity has occurred.

(To be concluded.)

NOTES ON DISEASES OF THE NERVOUS SYSTEM.

BY W. R. GOWERS, M.D., F.R.C.P.



I.

ON A CASE OF MILIARY SCLEROSIS OF THE BRAIN.

THE term "miliary sclerosis" was first applied by Drs. B. Tuke and Rutherford to a lesion found by them in the white substance of an atrophied cerebellar hemisphere in an insane patient. The lesion was chiefly microscopic, was only discovered after hardening, and consisted of minute spots of degeneration, in which there was little evidence of a process deserving to be called "sclerosis." The term was subsequently used by others to designate another microscopic lesion, since abundantly proved to be of artificial origin—an "artefact," as the Americans say. It is questionable whether the term "miliary" ought to be applied to a purely microscopic lesion. It is derived from that classical standard of size, a millet-seed (milium), and may with advantage be restricted to lesions not differing much in dimensions from the grey granulations of tubercle, to which the word is universally applied. Since the demonstration of the spurious nature of the lesion generally designated by this term the expression has fallen into disuse. I venture, however, to revive it as a designation for the lesion in the following case, not only because it accurately describes the morbid state, but also because it is the only term that does so, and the character of the morbid state is the only one which the term accurately connates. The case was observed several years ago, but temporary loss of the notes has prevented its earlier publication. They are unfortunately deficient in many particulars, but the case has at least the interest of extreme rarity.

The patient was a well-built man, aged fifty-nine, seen in consultation with Mr. E. C. Shoppee of Kentish Town, who kindly furnished me with some particulars of the early history of the case. The patient had had syphilis many years before. Recently, slight dyspeptic troubles occurred, and shortness of breath distressed him, which was found to be due to emphysema of the lungs and cardiac weakness. Six months before death his liver and spleen enlarged, and some ascites and anasarca appeared, the urine being free from albumen. Then his limbs gradually became weak, so that, at the end of about six weeks he needed help to walk across the room. He had difficulty in raising his arms. The elbows were flexed and rigid. The weakness increased to complete loss of power about two months after the onset. I then saw him with Mr. Shoppee and found the following condition. He presented no indication of mental change. The cranial nerves and special senses were normal, and the fundus oculi healthy. There was no difficulty in swallowing. The arms were completely paralysed, but very rigid, the elbows being flexed at a right angle. The fingers were flexed at the middle joints, as in hemiplegic rigidity. The legs were also completely paralysed. In neither arms nor legs was there any loss of sensation. The sphincters were competent. During the next week consciousness remained unaffected. Both spine became extended and remained so. Some power was preserved in the left arm and leg. A week later he had some twitching in the right leg, and a day or two afterwards he had several slight convulsive attacks, beginning in the left shoulder, affecting the left side and head only, and the arm more than the leg. Soon after these attacks he lost the power of speaking, mumbled in an unintelligible manner, became comatose, and died a fortnight after I saw him, about ten weeks after the onset of the nervous symptoms.

Permission could be obtained to examine only the brain. The arachnoid over the convexity was more opaque than normal. At the posterior part of each hemisphere of the cerebellum there was a small submeningeal extravasation. There was no excess of fluid in the ventricles or any large lesion in the brain. Throughout both hemispheres, and in all parts of them, the cortex contained minute reddish-grey spots, at the junction of the grey and white substance. In tint they were a little darker than the darkest grey substance (as that of the corpus striatum). They were more translucent in appearance than the grey matter of the cortex, and they were not depressed below the surface of the section. Their aspect was very like that of the areas of disseminated sclerosis. In size they varied from that of a mustard-seed, or a little larger, to the smallest point visible. Their size and distribution are shown in the accompanying diagram. (Fig. A.) In many places the section showed rows of these spots along the junction of the grey and white substance, festooning the convolutions. Here and there were larger and more irregular areas about an eighth of an inch in diameter, distinctly formed by the coalescence of the smaller spots. Their number is fairly represented in the figure, and they were equally abundant in all parts of the hemispheres. At two spots there was a more considerable change in the white substance of a convolution. One of these was about a square inch in extent on the inner and posterior part of the right occipital lobe. The white substance was mottled with reddish lines, mingled with some diffuse redness, and many grey spots, similar to those elsewhere, were scattered through this area, and

A, Section through the cortex cerebri. The black dots indicate the distribution and size of the spots of sclerosis. B, Section through the left lenticular nucleus and claustrum. C, Ditto right.

between them were spots and lines of yellowish tint, apparently degenerating cerebral substance. The consistence of this area was not diminished. This change did not invade the grey cortex. Another area of precisely similar aspect, but smaller, existed in the highest part of the left ascending frontal convolution, but also limited to the white substance. In the neighbourhood of this area the grey spots were especially numerous. The rest of the white substance of the hemispheres presented no abnormal appearance, but spots of grey degeneration, identical in aspect with those of the cortex, were numerous in the central ganglia. On the left side the anterior part of the lenticular nucleus was free from them, although they were abundant in the adjacent convolutions of the insula. The claustrum, however, was riddled with similar spots, the size of millet-seeds. In the rest of the lenticular nucleus the two inner segments contained very few, but in the posterior half of the outer segment (Fig. B) they were numerous, grouped chiefly along its outer border, adjacent to the external capsule; none could be seen in the caudate nucleus. In the centre of the optic thalamus was a rather larger spot of similar character; around this were many small spots like those elsewhere, some coalescing. In the right lenticular nucleus were similar spots, but fewer in number. The anterior extremity was free. In the outer segment was a larger irregular spot, one-sixth of an inch in diameter, apparently formed by coalescence. The claustrum (Fig. C) on this side also contained many; the caudate nucleus was free; many were scattered through the optic thalamus, all small. Beneath the corpora quadrige-

Digitized by Google

mina were two small spots. In the rest of the pons, medulla, crura cerebri, and cerebellum none could be found.

On microscopical examination (of sections, stained and unstained, kindly prepared for me by my colleague, Dr. Beevor) the affected patches were as distinct as to the naked eye. In addition many smaller areas were seen, too minute to be visible to the naked eye, but as well defined as the larger ones. All presented the same characteristics. At the periphery of the larger areas, and throughout the smaller ones, the change consisted of small round or oval cavities separated by septa, which had an indistinctly fibrous appearance, and were dotted with minute granule-like nuclei. The cavities in unstained sections were seen to contain clear or faintly granular material; in stained sections they appeared empty. The cavities varied much in size, some being very small, others larger, and they seemed to communicate. This vacuolated structure bore considerable resemblance to that of a sponge. Passing from the periphery towards the centre of the area, the substance between the cavities increased in thickness and in its fibrous aspect. In the normal tissue near the patches were seen spider cells with conspicuous processes. Similar cells became more numerous within the margin of the diseased area; these were, however, larger, with conspicuous nuclei, but with less distinct processes, some of which could be traced a short distance in the fibrous septa. Towards the centre these cells were still more numerous, larger, with larger nuclei. Smaller, rounded, nucleated cells were seen here and there within the cavities. The increased number of cells and thicker septa gave the centre of the patches a dense appearance, contrasting with the sponge-like periphery. The smallest spots consisted only of the spongy structure. None of the cells seemed to be altered ganglion cells, for the appearance was the same in the patches that were entirely within the white substance as in those that were partly in the grey cortex. Where a patch had developed in the centre of a convolution, among the longitudinal fibres, the cavities were elongated, and many of the cells were fusiform. The patches, large and small, had for the most part no connexion with vessels. Small vessels seen in some had a normal appearance, or presented only a slight increase of nuclei in the wall or slight thickening of the wall. A few were seen with a series of the altered spider cells along each side of the vessel. Away from these patches, however, the tissue beside some some vessels presented the spongy change above described; it did not extend far from the vessel, and showed no tendency to develop into areas of disease such as have been described. In other cases larger cavities were seen beside the vessels, fewer in number, and very irregular in distribution, with thin septa between them and little increase of the cells so conspicuous in the other diseased areas. Similar cavities were seen elsewhere in the white substance near the cortex; some of these had no apparent connexion with vessels, but others were arranged in lines as if indicating the course of vessels that did not come into the section. The grey cortex, apart from the areas of disease, had a normal appearance, and its ganglion cells showed no indication of degeneration.

The lesion in this case seems fairly to merit the term "sclerosis." Its naked-eye characters resembled perfectly those of insular sclerosis, and the microscopical characters are not inconsistent with the term. There was a wasting of the cerebral tissue, and an increase of fibrous tissue and glia-cells. It differed from insular sclerosis in size, seat, and multiplicity of the foci of disease. I have met with no recorded case of quite similar characters. It is, however, clearly allied to the changes that have been met with in rare cases of general paralysis of the insane. In a case of the latter disease, recorded by Dr. F. Greiff,[1] a lesion is described similar in size and seat, except that the central ganglia were unaffected. It differs in that the lesion was invisible in the fresh brain, and consisted in a "vitreous degeneration" of the cerebral tissue and cortical cells, starting everywhere from the vessels, and similar in character to a slighter lesion described by Simon in Bd. ii. of the same *Archiv*. I could discover no trace of a vitreous change in the case now described, unless the process of vacuolation be so described; but a partial relation to the vessels was distinct, and it is possible that the two cases present varieties of the same lesion. The peculiar localisation of the disease suggests a relation to vascular supply, although not necessarily a vascular origin. From all recorded instances of analogous lesions this case is distinguished by the sanity of the patient. Until the final coma there was no mental alteration. It is, then, of much interest as an example of a form of disseminated disease of the deeper cortical layer of the brain, and of the central ganglia, occurring apart from any form of insanity. The absence of an examination of the cord makes it impossible to refer the symptoms in the limbs, with certainty, to the cerebral lesion. It is, noteworthy, however, that in the case described by Greiff a similar rigidity was present.

THE FAMILY HISTORY OF CANCER PATIENTS.

By W. ROGER WILLIAMS, F.R.C.S.,
SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL, SURGEON TO THE WESTERN GENERAL DISPENSARY.

IN treating of this subject, some knowledge of the principles of biology and the laws of inheritance, as applied to the whole organic world, is absolutely necessary. I take it that lack of this knowledge is the chief cause of the recent epidemic of disbelief in the heredity of cancer, which is totally at variance with all that we know of these principles and laws. Therefore I propose to preface this account of my investigations into the family history of cancer patients with a brief general statement as to the nature and laws of heredity, as bearing on this subject.

In ultimate analysis it appears that reproduction is nothing but growth of the organism beyond its individual limit of size. We see this in the amœba, which reproduces itself by simple division. In every act of propagation a certain quantity of cell substance is transmitted from the parents to the child, and along with it the molecular motion peculiar to the parental individuals. The phenomena of inheritance are essentially dependent upon this material continuity and partial identity of the producing and produced organisms. The child is really flesh and blood of its parents. That the main structural characters of all organic beings are inherited is indeed universally admitted, and most naturalists are now agreed that even the smaller morphological details are similarly transmitted. Moreover, not only are those structures which have been inherited from ancestors transmitted to descendants, but also those peculiar variations which have been acquired during the lifetime of the individual. Examples of this are seen in plants and animals—e.g., copper beeches, weeping willows, supernumerary digits, &c. Indeed, it has been established as a general rule that any structure which has once varied in a particular way is henceforth more liable to take on that action again. Now, cancers and tumours must be regarded as morphological variations, and as such they are subject to these laws. On this subject Darwin remarks: "When amongst individuals, apparently exposed to the same conditions, any very rare deviation, due to some extraordinary combination of circumstances, appears in the parent—say once amongst several million individuals,—and it reappears in the child, the mere doctrine of chances almost compels us to attribute its reappearance to inheritance. Everyone must have heard of cases of albinism, prickly skin, hairy bodies, &c., appearing in several members of the same family. If strange and rare deviations of structure are really inherited, less strange and common deviations may be freely admitted to be inheritable. Perhaps the correct way of viewing the whole subject would be to look at the inheritance of every character whatever as the rule, and non-inheritance as the anomaly."

I trust that in these few brief remarks I have succeeded in making my views as to the heredity of cancer intelligible. I will now proceed to state the facts elicited by the analysis of the family history of 254 cases of uterine and breast cancer under treatment at the Middlesex Hospital during the years 1882, 1883, and 1884.

I. UTERINE CANCER (119 Cases).

The fathers.—Of 100 cases in which inquiries were made, in 86 the fathers were dead, and in 14 still alive. Their average age at death in 81 cases was fifty-nine years, the youngest twenty-six, the oldest ninety-five; 7 attained or exceeded the age of eighty; 12 died at or under forty. Of

Digitized by Google

those still alive, in 10 cases the average age was seventy-three years, the youngest sixty, the oldest eighty-two. They had died of, or were subject to, the following diseases:

Lung disease in 31 cases (31 per cent.): phthisis, 20; bronchitis, 7; others, 4.
Neuroses in 9 cases (9 per cent.): apoplexy, 5; insanity, 2; others, 2.
Heart disease in 3 cases.
Zymotics in 3 cases: typhoid fever, 2; "fever," 1.
Dropsy in 2 cases.
Rheumatic fever in 1 case.
Gout in 1 case.

Four of the fathers who had died of causes other than phthisis were, however, of phthisical families. Thus, of these 100 fathers, 24 were of decidedly phthisical families. There was not a single instance of cancer among the fathers, but 4 of them were of decidedly cancerous families. In 30 cases the causes of death were unknown.

The mothers.—Of 98 cases in which inquiries were made, in 80 the mothers were dead, and in 18 still alive. Their average age at death in 76 cases was sixty years, the youngest twenty-five, the oldest ninety-three; 10 died at or under forty; 9 attained or exceeded eighty. Of those still alive, in 15 cases the average age was seventy years, the youngest fifty-five, the oldest ninety. They had died of, or were subject to, the following diseases:—

Lung disease in 21 cases (21·4 per cent.): phthisis, 12; bronchitis, 8; pleurisy, 1.
Neuroses in 10 cases (10 per cent.): apoplexy, 9; epilepsy, 1.
Cancer in 8 cases.
Dropsy in 4 „
Zymotics in 4 „
Heart disease in 3 „

Five of the mothers who had died of causes other than phthisis were, however, of phthisical families. Thus, of these 98 mothers, 17 were of decidedly phthisical families. Eight of the mothers died of cancer, and in 5 cases, though the mothers had not died of this disease, they were of cancerous families. Thus, of these 98 mothers, 13 were of decidedly cancerous families. In 25 cases the causes of death were unknown.

Consanguinity in parents.—As to this, inquiries were made in 20 cases. In 1 only were the patients blood relatives; in this case they were first cousins; there was no history of cancer or phthisis in either parent.

The patients' brothers and sisters.—In 56 families, one or more of the adult members had died of, or were subject to, the following diseases:—

Lung disease in 35 families: phthisis, 33; others, 2.
Cancer in 6 „
Zymotics in 6 „ typhoid fever, 2; scarlet fever, 2; others, 2.
Dropsy in 5 families.
Neuroses in 4 families: insanity, 2; apoplexy, 1; brain disease, 1.
Heart disease in 4 families.
Scrofulous affections in 3 families.

Of the families in which phthisis prevailed, more than a single member had died of it in 15. The number of children in each family was noted in 92 cases, with the result that the smallest family consisted of 1 (3 instances), the largest of 18 (in 2 instances), the average being 7·5.

The occurrence of cancer.—Of 108 families in which this [illegible] was specially investigated, there was a history of malignant disease in 23 families (21·3 per cent.); in 2 cases there was a history of non-malignant tumours. The relatives affected with cancer and the seats of the disease may be grouped as follows:—

[illegible]'s sisters (in 2 families): stomach, 1; face, 1.
[illegible]'s brothers (in 2 families): uterus, 1; arm, 1.
[illegible]'s cousins (in 1 family): breast, 1; neck, 1; [illegible].
[illegible] mother (in 1 family): uterus, 1.
[illegible] (in 6 families): uterus, 2; breast, 2; [illegible], 1; face, 1.
[illegible] sisters (in 6 families): uterus, 2; breast, 2; [illegible], 1; intestine, 1; abdomen, 1.
[illegible] brother (in 1 family): stomach, 1.
[illegible] (in 9 families): uterus, 5; breast, 1.
[illegible]'s daughter (in 1 family): uterus, 1.

In one case the patient's maternal grandmother, mother, mother's sister, and patient's two sisters, all died of cancer of the uterus. These 30 seats of the disease may be grouped thus:—Uterus, 12; breast, 6; stomach, 3; face, 2; all others, 7.

The occurrence of phthisis.—Of 101 families, one or more relatives had died or were the subjects of phthisis in 49, or 48·5 per cent. In 45 families more than a single relative had suffered from this disease. The relatives thus affected may be classed as follows:—

Father's father	in 1 family.
Fathers	in 17 families.
Father's brothers and sisters	in 14 „
Mothers	in 10 „
Mother's brothers and sisters	in 7 „
Patient's brothers and sisters	in 34 „

The combination of cancer and phthisis.—Of 101 families there was a history of both phthisis and cancer in 10. Thus:

Phthisis	Father's side in 5 cases.
	Mother's side in 1 case.
	Patient's brothers and sisters in 4 cases.
Cancer	Father's side in 1 case.
	Mother's side in 4 cases.
	Patient's brothers and sisters in 1 case.
Cancer & phthisis	Father's side in 1 case.
	Mother's side in 3 cases.

II. BREAST CANCER (135 Cases).

The fathers.—Of 108 cases, in 99 the fathers were dead, and in 9 still alive. Their average age at death, in 94 cases, was 62·5 years; the youngest thirty, the oldest ninety-three; 13 attained or exceeded the age of eighty. Of those still alive, in 7 cases the average age was 71·2 years; the youngest sixty, the oldest eighty-six. They had died of, or were subject to, the following diseases:—

Lung disease in 27 cases (25 per cent.): phthisis, 20; bronchitis, 7.
Neuroses in 10 cases (9·2 per cent.): apoplexy, 7; insanity, 2; cerebral softening, 1.
Heart disease in 10 cases (9·2 per cent.).
Zymotics in 6 cases (5·5 per cent.): cholera, 2; others, 4.

Cancer	in 4 cases (3·7 per cent.).
Dropsy	in 4 „ (3·7 per cent.).
Old age	in 3 „
Diabetes	in 1 case.
Ulcer of leg	in 1 „
White swelling of knee	in 1 „
Chronic rheumatism	in 1 „

Twelve of the fathers who had died of diseases other than phthisis were, however, of phthisical families. Thus, of these 108 fathers, 32 (29·6 per cent.) were of decidedly phthisical families. There were 4 deaths from cancer among the fathers, and in 7 other cases, though they had not died of cancer, they were of cancerous families. Thus, of these 108 fathers, 11 (10·1 per cent.) were of decidedly cancerous families. In 31 cases the causes of death were unknown.

The mothers.—Of 105 cases, in 89 the mothers were dead, and in 16 still alive. Their average age at death in 88 cases was 62·5 years; the youngest twenty-five, the oldest ninety-nine years and nine months. Of those still alive, in 12 cases the average age was 71·7 years; the youngest sixty, the oldest eighty-four. They had died of, or were subject to, the following diseases:—

Lung disease in 25 cases (23·8 per cent.): phthisis, 16; bronchitis, 5; pneumonia, 3.
Neuroses in 7 cases (6·6 per cent.): apoplexy, 6.
Dropsy in 7 „ (6·6 per cent.).
Cancer in 5 „ (4·7 per cent.).
Zymotics in 3 „ (2·8 per cent.): cholera, 2; typhoid, 1.

Liver disease	in 3 cases (2·8 per cent.).
Diabetes	in 1 case.
Spinal disease	in 1 „
Heart disease	in 1 „
Inflammation of bowels	in 1 „

Five of the mothers who had died of causes other than phthisis were, however, of phthisical families. Thus, of these 105 mothers, 21 (20 per cent.) were of decidedly phthisical families. Five of the mothers died of cancer,

Digitized by Google

and in 11 cases, though the mothers had not died of cancer, they were of cancerous families. Thus, of these 105 mothers, 16 (15·2 per cent.) were of decidedly cancerous families. In 31 cases the causes of death were unknown.

Consanguinity in the parents.—Of 18 cases in which inquiries were made, there was a history of consanguinity in the parents in 3. In 1 case the parents were first cousins. The father died of phthisis, and the paternal grandmother of cancer of breast. In the other 2 cases the parents were second or third cousins. In one of these cases the father died of phthisis, and his mother of cancer of the breast; in the other there was no history of cancer or phthisis, but the father's father died insane.

The patient's brothers and sisters.—In 75 families, one or more of the adult members had died of, or were subject to, the following diseases:—

Lung disease in 37 families: phthisis, 33; bronchitis, 2; others, 2.
Zymotics in 10 families: typhoid fever, 3; small-pox, 2; others, 5.
Heart disease in 7 cases.
Dropsy in 5 „
Cancer in 4 „
Neuroses in 4 „ apoplexy, 3; cerebral softening, 1.
Scrofulous diseases in 3 „
Rheumatic fever in 1 case.
Diabetes in 1 „
Inflammation of bowels in 1 „

Of the families in which phthisis prevailed, more than a single member had died of it in 13. Of 90 families the average number of members was 8·5, the smallest 1 (single instance), the largest 17 (2 instances).

The occurrence of cancer.—Of 114 families, there was a history of cancer in 28, or in 24·5 per cent. The relatives thus affected and the seats of the disease may be shown as follows:—

Father's grandfather (in 1 family): nose.
Father's grandmother (in 1 family): breast.
Fathers (in 4 families): breast, lip, hand, internal.
Father's sisters (in 10 families): breast (5), mouth, internal, liver, face, scalp.
Mother's grandmother (in 2 families): breast, uterus.
Mothers (in 6 families): breast, uterus, tongue, internal; not stated, 2.
Mother's sisters (in 5 families): breast (4), internal.
Mother's brother (in 1 family): groin.
Sister of mother's father (in 1 family): breast.
Female cousin on mother's side (in 2 families): breast; not stated.
Patient's sisters (in 4 families): breast, 3; not stated, 1.
Patient's brothers (in 2 families): throat, back.
Patient's daughter (in 1 family): internal.

In 3 cases there was a history of cancer in the families of both parents. In 6 cases more than a single relative was affected. These 40 seats of disease may be grouped thus:—Breast, 18; "internal," 16; uterus, 2; all others, 13.

The occurrence of phthisis.—Of 112 families, one or more relatives had died or were the subjects of phthisis in 65, or 58 per cent. In 30 families more than a single relative had died of this disease. The relatives thus affected may be classed as follows:—

Both paternal grandparents in 1 family.
Paternal grandmother in 1 „
Both parents in 5 families.
Fathers in 14 „
Father's brothers and sisters in 17 „
Mothers in 11 „
Mother's brothers and sisters in 7 „
Patient's brothers and sisters in 32 „

The combination of phthisis and cancer.—Of 112 families, in 15 there was history of both phthisis and cancer. Thus:

Phthisis	Father's side	in	9 families.
	Mother's side	in	1 family.
	Patient's brothers and sisters	in	2 families.
Cancer	Father's side	in	1 family.
	Mother's side	in	10 families.
	Patient's brothers and sisters	in	2 „
Cancer & phthisis	Father's side	in	2 „
	Mother's side	in	3 „

THEORY OF CANCEROUS INHERITANCE.[1]

By H. PERCY DUNN, F.R.C.S.,
ASSISTANT OPHTHALMIC SURGEON AND PATHOLOGIST AT THE WEST LONDON HOSPITAL.

"As the births of living creatures," wrote Bacon in 1625, "at first are ill-shapen, so are all innovations which are the births of time." This, I venture to believe, is true in its application to the subject which it is my intention now to discuss. I believe that the pregnancy, so to speak, of the non-identity of cancer with heredity has begun, that the metaphorical embryo is satisfactorily developing, that time will enable us to chronicle a new birth in the history of a foul disease, and that in the future we shall be able to show unequivocally that there is no such thing as the hereditary transmission of cancer; and the facts, in my opinion, are accumulating to this end. What, if we cannot show directly that cancer is not hereditary, can the surgeon hope for from operative treatment? What more than despair can the suffering patient exhibit whose disease has been pronounced to be hereditary by the attending surgeon? These are matters to us confessedly of the greatest importance. When therefore we calmly weigh the direful results to which cancer as a disease gives rise, upon the grounds even of humanity, it is right that each particle of evidence bearing upon its supposed hereditary transmission should be sifted and exposed to the ptyalinistic effect of scientific research for the purpose of proving its value.

And now cancer is said to be hereditary—upon what grounds? The laws governing inheritance, as Darwin observes in the "Origin of Species," are for the most part unknown. It is impossible to say why the inheritance of family characteristics should be limited by age, sex, and conditions of life; and it is still more difficult to understand why in some instances a child, instead of inheriting the peculiarities of its parents, should resemble its uncle or aunt, grandfather or grandmother, or some ancestor even still more remote. It has been well said by La Place that the "surest method we can adopt for our guidance in the search after truth consists in raising phenomena by induction to laws and laws to facts," and it is conceivable that the adoption of this principle is admirably adapted for an inquiry which relatively is so obscure as the hereditary transmission of natural or morbid peculiarities. Heredity, nevertheless, is, as is well known, operative as a fixed principle in accordance with three definite and unvarying laws. There is, in the first place, direct heredity, where some peculiarity is transmitted immediately from the parent to the offspring; then we have indirect heredity, where the peculiarity is derived from an uncle or aunt; lastly, there is atavic heredity, where a child inherits some striking feature peculiar to its grandfather or grandmother, or which has been known to belong to some remote ancestor. Now, cancer is held to be hereditary because the disease has occurred consecutively amongst the members of certain families, and because its occurrence has been considered to be consonant with the principle of the hereditary transmission of structural peculiarities. Sir James Paget has observed—and I must apologise here for introducing his well-known statistics—that amongst the cancerous patients whom he saw at the hospital, one in six could give a family history of cancer. In the course of time he made similar inquiries amongst his private patients, and he then deduced the fact that one person out of every three who came to him with cancerous disease had knowledge of the previous manifestation of cancer in the family. With this record, unsupported as it may be by collateral facts, we stand thus: that cancer is apparently hereditary, and not only hereditary, but hereditary to a high degree. The evidence disclosed by these facts concisely expresses the grounds upon which cancer is considered to be hereditary, and, dealing with the question in a general sense, I will now proceed to state the reasons which impel me to dispute the conclusions to which statistics of this nature are calculated to lead.

In the first place, it is essential again to refer to the fact that the theory of cancerous inheritance is based simply and solely upon the consecutive appearance of the disease

[1] A paper read at the meeting of the West London Medico-Chirurgical Society on Nov. 6th.

Digitized by Google

in certain families. Apart from and beyond this peculiarity it fulfils in no sense whatever the characters of an hereditary disease. "Heredity," says Quatrefages, "which is essentially a preserving agent, becomes an agent of variation when it transmits and accumulates the modifying actions of the conditions of life."[2] Does cancer, I may ask, become an agent of variation? Do the conditions of life which we believe to be favourable to the production of the disease in any way impress themselves upon the human offspring sufficiently to enable us to recognise any influence of heredity in their appearance? Is there such a thing as a cancerous diathesis, equivalent to what we understand by the gouty diathesis, the tubercular, or the syphilitic? Occasionally a child is born whose parent before lactation is completed becomes the subject of cancer of the breast. Now here, in the midst of a disease which is active, is it not natural to expect some impress of it, if nothing more, to be visible in the offspring? But are we able to say, Here is a child who will become cancerous, or because the child's parent was cancerous therefore it will suffer in this way or that? No; a child inherits no pains or penalties from a cancerous parent. It possesses no special, pathological, or structural features which might have come to be regarded as pathognomonic of cancerous disease. It does not necessarily exhibit any ill-health or differ in any respect from a healthy child born of healthy parents. And what is true of the child is true also of the adult. Therefore the conclusion seems obvious and indisputable that, whilst syphilis, gout, and tuberculosis, which are correctly described as constitutional diseases, permanently modify the structure and functions of the body, cancer cannot be included in this category, for, commencing as a local disease, its effects, it is true to say, are never transmitted. A man may be gouty without having had an attack of gout, the origin of his gout having been hereditary. A man may suffer from the effects of inherited tuberculosis without being actually tubercular. A child may be syphilitic in its face, in its teeth, in its eyes, without being actively syphilitic, the disease having been derived by inheritance and remedied at the time by treatment. These are examples of diseases which are unquestionably hereditary; and in the case of cancer, assuming it to be hereditary, analogy would lead us to expect a similar condition of things to prevail. But no. There is no such thing—even in the most recent text-books on medicine—as, say, a cancerous stomach, a cancerous neuralgia, a cancerous ache or pain, without cancer. A person is either cancerous or he is not, and he is not so until he becomes so by exhibiting unequivocally in some organ or part the disease in its primary form. It is clear, then, that if he has inherited cancer he has not inherited much. For, obviously, cancer must be an exceptionally benign disease—before it becomes cancer—in those cases, indeed, in which it is believed to be inherited. For a man with an inherited cancerous taint must patiently wait until the near approach of the last scene of all which ends his strange eventful history, before his morbid patrimony can become an accomplished fact. Now there is something here which calls for special comment. Either the man is exceedingly accommodating for being good enough to wait, or the disease is to be specially commended for exercising such patience. It is pleasant to be able to record this fact. The disease exhibits a feature here which enables us to assign to it even a personality which is worthy of example. Sometimes, however, man frets it into activity before its time by smoking clay pipes and rummaging about in soot. But then, in these cases, of course he has only himself to blame. Those of us who are convinced that cancer is hereditary must unquestionably admit that, to use a commonplace phrase, the disease is generally called upon "to play a waiting game." But is this belief scientific—is it philosophical? I hold that it is not so.

Now it will appear plain from all these remarks that I emphatically oppose the belief in the hereditary transmission of cancer. Well, this is precisely the case. I deny unconditionally, upon grounds which seem to me to be incontrovertible, that the theory is tenable. In other words, to formulate my opinion, I hold that cancer as a disease is never transmitted. But, if cancer as a disease is not hereditary, in what manner can the occurrence of consecutive cases of the disease in certain families be explained? It is possible to reply to this in two or three ways, and the first which I will consider here is that of predisposition.

[2] "The Human Species," International Scientific Series, vol. xxvi., p. 258.

Now I am not sure that it is not impossible to inherit a a predisposition to cancerous disease. It may be that parents are able to transmit to their offspring a predisposition to cancer. But what is the inheritance of a predisposition in comparison with the inheritance of a disease? They are two vastly different things. The one can be made to perish by rendering the surroundings inimical to its existence; the other is a reality, an unalterable fate. It is by no means true universally that heredity implies simply a tendency to this or that disease.[3] Does the new-born infant of syphilitic parents inherit simply a tendency to syphilis when its wizen appearance, its scaly eruption, the gross display of colour on its nates betoken the active transmission of its parent's disease? Such an infant, if it survived, would in after-years—nay, indeed, throughout life—display to the observant surgeon, not the tendency which had come to it by inheritance, but the fate to which it had been born. Now what is predisposition, resolved into its simplest terms and reduced to a definition founded upon scientific fact? It is almost impossible to define it. Presumably it implies some transmitted functional insufficiency of organs as a whole or of tissues as a part. There need not probably be any particular structural departure from normal growth, but conceivably simply a diminution of vitality, an inherent want of power in some organ or part which has followed as the result of particular or general disease in the parent. Analogically, perhaps, predisposition may be described as the shadow of a disease, as a disease without its substance—the reflection, as it were, in the offspring, distinct from the repetition, of the morbid types common to one or both parents. It is, however, impossible to generalise, except to a very small extent, in matters relating to the hereditary transmission of morbid peculiarities; and consequently conjecture carried further in this direction would be more prone than otherwise to lead us into error. Common experience has taught us the power we possess of causing the inherited tendency to a disease to subside by adopting certain measures of precaution which are known to be inimical to its existence. This fact is too well known to require more than simply mentioning; but it is not possible to over-estimate its importance, and I will here briefly refer to its application in regard to cancer. It is indisputable that if we admit categorically that cancer as a disease is not transmitted, there is some reasonable hope for believing that some check could be placed upon it by turning attention to the causes and conditions with which it invariably seems to be associated. The strongest element undoubtedly in the production of cancer is age. With this of course we could not deal. But even the most favourable age, together with, if you will, the strongest family history of cancer, would, I firmly believe, not be sufficient to provoke the disease without some extraneous condition, which perhaps should be described as an exciting cause. And in relation to the various causes and conditions with which cancer is allied we have now an accumulation of facts, some of which up to the present are certain, and the rest reasonably possible. Statistics to which I have elsewhere drawn attention have unmistakably shown that the geographical area within which these islands is included is highly favourable to the disease.[4] Upon these grounds, therefore, it is evident that the prevalence of cancer amongst us depends primarily more or less upon this fact. Cancer, therefore, in England should be regarded as a racial disease, as distinct from a disease of the individual. By virtue of the climatic surroundings of England it is probable that English people as a race are inherently much more liable to cancer than the inhabitants of, say, the Faroe Islands and Iceland, in which the disease is said to be unknown. This susceptibility undeniably forms a part of the national family likeness. It has its counterpart, to name only a single example, in the immunity from yellow fever enjoyed by negroes and their half-breeds. Thus, regarded in this light, the predisposition to cancer in England being racial in its origin, and not individual, the primary origin of the disease in the large majority of persons who suffer from cancer amongst whom no family history of cancer can be traced, may be in some respects explained. And perhaps it would be expedient for those families in whom cancer has appeared more than once to emigrate to some Elysian district in the world where the

[3] British Medical Journal, Sept. 26th, p. 607.

[4] An Inquiry into the Causes of the Increase of Cancer (British Medical Journal, April, 1883).

Digitized by Google

disease is unknown. If this should be ineffectual something different could be tried. Cancer leaves savages alone—that is, uncivilised men and women. To return to a primeval condition would certainly in these days be a novelty, and I commend the suggestion to those who are in search of such things. It would have some advantages, and might prove popular for a time; but it is doubtful whether the wild man would appreciate the experiment or reciprocate the feeling of gratification of which all things novel become the source.

I will now briefly discuss the relation of cancer in regard to the social position of the patients. What do we learn? Taking Gross's statistics as an example, we find that out of 712 women with cancer of the breast, 88·22 per cent. were or had been married. Of these, 83·91 per cent, had borne children and 16·09 were sterile, while 11·77 were single. What a remarkable statement is this! We are here again brought face to face with the astounding influence exercised by fecundity upon cancer. It is almost certain that if every virgin in England at this moment maintained her *status quo ante* in this respect until the end of her natural life the female mortality from cancer in the future would be infinitesimal in comparison with present records. The question of marriage is thus an eminently important one in relation to cancer as far as the female is concerned, and yet it is one obviously far beyond the influence of politicians, moralists, or surgeons.

Let me now, however, draw attention to the somewhat remarkable fact that in those families whose cancerous history has been quoted as evidence of the hereditary theory, the disease has almost invariably been transmitted in the female line. I say almost invariably, because of course there are exceptions to every rule. Thus in Warren's case, in Paget's, in Velpeau's, in Broca's, the female members of the families concerned predominently—almost entirely—suffered from the disease. Before, however, determining the question of hereditary transmission in these cases, it is perhaps as well to take into consideration certain factors which it is scarcely possible to overlook. For instance, we know that cancer as a disease is not limited in its appearance to one sex. It is true that it is more common in women than in men, but the truth of this only extends as far as the fact that women possess a uterus and functionally active breasts, for both of which organs the disease exhibits a marked predilection. In short, then, assuming the disease to be hereditary, it should be transmitted equally to both sexes, and not expend its virulence upon the female line alone. Again, all women who have borne children are liable to cancer, as statistics have abundantly shown. Furthermore, the briefest experience of cancer in women is sufficient to reveal the wholesome dread and misgiving with which the disease is regarded, and it is quite comprehensible that the sympathy and mental disturbance excited by a suffering relative succumbing by slow degrees from cancer of some organ might readily become the *fons et origo* of the disease in another member of the family. Thus the inexorable logic of facts compels the conclusion that if cancer can be met with frequently without any hereditary history, heredity can scarcely be regarded as exercising any potential influence in its production, more especially in those cases where other and more important factors are present, with certain of which the disease is always inseparably associated.

In bringing forward these facts and opinions—and I am bound to admit that the latter predominate—I have not endeavoured to exhaust the subject to which they relate; but rather my object has been to extract the most salient features of the case, and appear as a counsel with his brief urging the claims of a client in whom he has more than an ephemeral interest. The advocacy of a cause of this nature involves the discussion of many complex topics; it necessarily deals with problems of science, of which the solution cannot be too frequently essayed; it leads the inquirer into many a cul-de-sac of pathology, from which it is often a difficult matter to effect a graceful retreat. But whether or not we shall ever determine the influence of heredity upon cancer depends confessedly upon whether or not we are prepared to sink the belief which has been bred of unsupported facts, and to struggle onwards patiently seeking and hopefully expecting some gleam of light to disperse the obscurity of the pathology of the disease.

The Sanitary Committee of the Bristol Town Council have adopted Sir J. Bazalgette's recommendation respecting the disposal of the sewage of that city.

ON THE

IMPLICATION OF THE MASTOID BONE IN EAR DISEASE.[1]

BY SIMEON SNELL,

OPHTHALMIC SURGEON TO THE SHEFFIELD GENERAL INFIRMARY AND TO THE INSTITUTION FOR THE BLIND.

AMONG the more important diseases affecting the hearing apparatus must be counted those attacking the mastoid process, occasioning as they do in many cases danger, and giving rise to very proper alarm. In this communication I purpose recording cases from my own practice, which will indicate varieties as to the manner and degree in which the process is affected, and will illustrate also the methods of treatment pursued. It is only rarely that the mastoid process becomes the seat of disease independently of an affection of the middle ear; Mr. Pierce, of Manchester, has, however, recorded[2] an instance in which suppuration in the process occurred without implication of the tympanic cavity; other cases are also reported, but they are far from common. Generally speaking, there is associated disease of the middle ear, either of an acute or frequently of a chronic character.

Discharges from the ear are, it is well known, by no means infrequent; and patients so suffering constitute a good proportion of those seeking treatment in aural cases, and their number would be largely increased if the importance of attention to and the danger of neglecting such cases were recognised. It is high time the old fable that such discharges had better not be stopped be driven out of the heads of the public, opposed as it is to sound surgical teaching. "It is even," says an American aurist,[3] "gravely asserted that such a discharge is salutary, as if our Creator would not have made the human race with such a one if it were necessary." The offensive character of the discharge, which renders him a nuisance to others, is occasionally the reason that induces a patient to seek advice; but, whatever the cause, it is clearly our duty to counsel steady treatment until the ear is in a healthier condition. In conscientiously fulfilling our duties, however, we not uncommonly labour under disadvantages. Patients have been accustomed in many cases to treat the matter with such levity that the frequent consultations or continued attendances are, it would seem, viewed by them as a means to an end, the object being to put fees into the medical man's pocket. It is thus difficult in some cases to keep patients under observation sufficiently long to render all the services of which our art is capable. It is no part of my subject to enter into the various causes of discharges from the ear, nor of the dangers associated with such conditions; but I have dilated thus widely on this matter because of the close connexion between such states and the subject under consideration. A free exit to all tympanic discharges is a matter of the first importance. The late Mr. Hinton observed:[4] "When threatening symptoms declare themselves, such as rigors, with or without ceasing of the discharge, pain in the ear or side of the head, giddiness, fever, or loss of power of any of the muscles, the aim of the treatment is simple—namely, to subdue any newly arisen inflammation, and, above all, to secure a perfectly free exit for pus, wherever it may be. In the vast majority of cases, impeded discharge is, or has been, the primary cause of the evil." The truth of these words will be exemplified in the cases about to be related.

In the first place let me refer to the case of a man, aged about twenty-five, recently under my care. He had been the subject of ear disease for about four years, coming on after picking the left ear with a pin, and injuring, as he was told at the time, the drum. The left meatus was filled with a polypus; and he complained, moreover, of giddiness, pain in the ear, over the mastoid, which was also a little tender, and over the head, and he suffered from sleeplessness. The meatus was cleared of the polypus. The Eustachian tube was pervious, but at first, with Politzer's bag, no air passed externally because the orifice in the tympanum was closed

Digitized by Google

by the polypoid condition of the cavity. A little later a large piece of bone from the tympanic wall was removed. Boracic acid lotion was used; and with the re-establishment of a ready exit for pus by the Eustachian tube and external meatus, the symptoms, pain, giddiness, &c., rapidly disappeared, and the discharge ceased.

The next case, also, is an example of involvement of the mastoid, which threatened to be serious, with stoppage of the discharge and subsidence of the symptoms, when exit for the discharge was re-established.

A young girl, aged fifteen, was sent to me by her medical attendant on April 13th, 1883. Her history was briefly this. About two years before she suffered from pain in the left ear, and it is said to have "gathered and burst." In a short time the discharge ceased. About six weeks before coming to me she had sore-throat, and when this had subsided, intense pain again commenced in the ear, which began to discharge, and afterwards ceased. When discharging the ear was free from pain, but directly it stopped the suffering was distracting. It came on in this way, discharging and ceasing five or six times. For some little time there had been swelling behind the ear, and recently it had become worse, and the pain was very severe. She had had very little sleep for three weeks. Examination showed over the mastoid and upper part of the neck a good deal of swelling, not much redness, but it was tender to the touch. There was pus in the ear, but the meatus was so occluded by swelling that a good view far down was impossible. The Eustachian tube was pervious, and the membrana tympani was perforated.

Here let me draw attention to a symptom which is very characteristic of mastoid inflammatory mischief. Allusion is made to the peculiar way in which the external ear loses its manner of lying more or less flat, and stands straighter out, and forms something of a right angle with the head. It should at once attract attention and suggest an examination of the mastoid. Little or no mention is accorded to this condition in books.

To return to our case. It appeared very probable that operative measures might be required, but, in the first place, the following line of treatment was decided upon, and was eminently satisfactory. She was confined to her room; poppy fomentations were frequently applied to the mastoid, and it is believed leeches as well, but the notes do not mention it; boracic acid lotion, warmed, was used for cleansing the ear, the importance of which was duly urged, and inflation with Politzer's bag was employed. A gargle was ordered also for the throat. Under these measures the mastoid swelling and pain rapidly disappeared, and she was soon out of my hands.

Another case under treatment at the same time was very similar to the one just related. There was not, however, in this case the marked obstruction observed in the other, but the mastoid affection subsided under the same treatment.

In April, 1883, a young man came to me. He had suffered in the right (?) ear for two weeks previously—the result, as he thought, of "cold." It commenced as a tickling in the ear, and later on a discharge from the meatus began. Then he suffered from pain behind the ear, which was very severe, and could not sleep. The pain in the ear had never been of a severe character. When seen by me the mastoid was somewhat swollen and puffy, and tender to the touch. Here the same line of treatment was pursued as in the last case. Leeches were applied to the mastoid, a lotion of Condy's fluid was employed for cleansing the ear, and the air douche was used for securing the perviousness of the Eustachian tube. The symptoms speedily subsided.

The instances just related have been those in which the implication of the mastoid has been only slight compared with what in many is the case. The prognosis is favourable, Politzer says, when there is a sufficiently free escape of pus from the tympanic cavity and from the external meatus. For this reason cleansing of the ear is an important part of the treatment. Boracic acid is my favourite lotion, but Condy's fluid, carbolic acid, and other lotions are admissible. The tympanum may be cleansed by the catheter in the Eustachian tube, a plan Politzer recommends, but it is out of the question with children. Internal medications are most valuable; iodine and belladonna seem also to act well in some cases.

As has been said, there are cases in which the symptoms are much more intense than those already referred to. The swelling over the mastoid region may be very great, extending into the head above and into the neck below; and the skin may be reddened, brawny, and œdematous. Moreover, the pain suffered may be of the most intense character, and there may be associated pyrexia, delirium, and other alarming symptoms. The extent and danger of the implication of the mastoid is not, however, in all cases to be measured by the amount of swelling on its surface.

On May 1st, 1882, a middle-aged clergyman from a little distance consulted me, under the following circumstances. Eight weeks previously he awoke one night with "earache," which continued very severe for four or five hours; he noticed a "crack" in the ear, and then a discharge came from it of a very offensive character. Latterly he had suffered from throbbing over the mastoid and side of the head. At the time of his visit there was no discharge from the ear, and the membrana tympani had healed. A watch (hearing distance forty inches) was heard only in contact; the Eustachian tube was pervious, but hearing was not improved after the passage of a catheter. There was no appreciable swelling over the mastoid, but firm pressure elicited a little tenderness. I communicated with his medical attendant, expressing the opinion that there had been suppuration in the tympanum, that there had been extension of the disease to the mastoid, and that, if suppuration in the cells had not already taken place, the condition was such that operative interference might at any time be demanded. It was not until May 16th that news of his progress reached me; his medical man, writing at that date, stated that his condition had not improved, but that the mischief in the mastoid cells had extended. On the 17th I visited him, together with his medical attendant and a medical relative. His condition was found to be rather alarming: pain of the most intense character was felt in the mastoid region and head, sleep had been absent, and there were delirium and pyrexia. The mastoid region was much swollen, tense, and brawny, but with only an indistinct feeling of fluctuation; the swelling extended above into the head and below into the neck. It was decided to cut down on to the mastoid, and if necessary to perforate the bone. Accordingly, under ether, a free incision was made behind the ear through the thickened tissues; about a dessertspoonful of pus immediately escaped, and the bone was found eroded and readily gave way. Free poulticing of the wound was advised. No opportunity has occurred of my again seeing the patient; but on the 19th his medical attendant wrote to me, saying that he was doing well, and he ultimately made an excellent recovery.

A somewhat similar case[7] to this I related before the Society a few years ago, and will only make brief reference to it now. The symptoms were just as severe and urgent in a man aged forty as in the one I have just mentioned. On cutting down to the mastoid a little pus escaped, and with a director an opening was found in the bone. The director was pushed further into the mastoid, and the opening was enlarged by levering it about in different directions; pus then freely escaped. He made a rapid recovery.

Recently I have seen with a medical friend the mastoid involved in two little sisters—delicate strumous children. In both the primary tympanic mischief was recent. In the elder, aged five, the swollen and tender mastoid subsided under warm poppy fomentations, cleansing the ear with boracic lotion, and inflation with Politzer's bag, together with a chlorate of potash gargle for the throat. In the younger, aged three, the course was different. She had suffered a little from earache and discharge for a few days, but it was only on January 23rd that she complained of actual pain. The next day this had increased, and my medical friend discovered that the mastoid was implicated. Warm poppy fomentations and boracic acid lotion for the ear was prescribed as in the last case. At our consultation the following day (January 27th) the ear was noticed to be straightened out from the head, and there was considerable swelling and tenderness over the mastoid; there had been rigors and pyrexia, and the child was much upset. Politzer's bag was used and the treatment continued. By the 29th the condition was worse. Under chloroform an incision was made down to the bone; a little pus escaped, and the bone was eroded. Poultices were applied to the wound, which was also syringed with boracic acid lotion; the treat-

ment for the ear was continued. The symptoms quickly subsided. I have since heard that a piece of necrosed bone has come away.

Another variety of cases may be unattended with swelling over the mastoid, and these are often among the most serious. The localised pain may be as intense as, or more so than, in any of the foregoing instances, and there may or may not be tenderness on deep pressure. The constitutional disturbance may be great, and whilst suppuration is taking place in the mastoid cells the unhappy state is aggravated by the inability for the imprisoned pus to find a mode of exit. These are among the extremely grave instances of implication of the mastoid, and it would appear not unlikely that the real nature might be overlooked or confounded with meningitis or some cerebral disorder. At all events, they are a class of cases that demand very decided treatment, the importance of which has been urged by Hinton, Dalby, Troeltsch, Politzer, and a host of others. The case next related caused my friend Dr. Martin (with whom I saw the patient) and myself to fear at one time that it would be of the serious nature just indicated, and was one of considerable anxiety.

The patient, a young gentleman of about twenty-three years, was first seen by me in 1877. Twelve years before he had had scarlet fever, and had since suffered from discharges from the ears. Both drums were destroyed; the lining membrane of the right tympanum was villous-looking. The left ear heard the watch on contact, the right at two inches ($\frac{2}{6}$). There was obstruction of both Eustachian tubes. This part of the case may be left with stating that with Politzer's bag and catheter the Eustachian tubes were rendered pervious, and at the end of a month the discharge had ceased, a result which held good when seen again some time later. On Feb. 2nd, 1883, Dr. Martin asked me to see him. He had just recovered from an attack of broncho-pneumonia, and a few days before my visit he had been seized with pain in the right mastoid; this had been of a very severe character, and had occasioned much loss of sleep. Leeches had already been applied with some temporary relief, and so had warm fomentations, and the application also of belladonna extract, with similar benefit. In spite of these remedies, however, and chloral as well, the suffering became aggravated. When I saw him the pain was confined to the mastoid, from which it ran into the jaw, especially the inferior maxillary articulation. It was at times less severe than at other times. There was no swelling to speak of over the mastoid, and only deep pressure elicited tenderness. The discharge from the ear had not been great. The ears were inflated with Politzer's bag, and boracic acid lotion was ordered; otherwise, the local applications were continued, and leeches, from which the patient appeared to have derived some relief, were re-applied. The next day he appeared, if anything, a little relieved; but this proved to be merely a temporary subsidence, for when we met again on the 6th his symptoms were aggravated, and it was decided to do what we had discussed at the outset—viz., cut down over the mastoid on to the bone. This was accordingly done, the patient preferring to have it performed without an anæsthetic. The incision, about an inch and a half in length, was carried through the periosteum; bleeding was encouraged, poultices were applied, and measures were taken to prevent the early closing of the wound. Great relief was immediately experienced, his symptoms soon disappeared, and we had the pleasure of seeing him before long restored to convalescence.

Enough has been said respecting the foregoing cases to indicate the different ways in which the mastoid process may suffer. They have been grouped thus rather than separated into periostitis or suppuration of the mastoid, because in practice the cases run much into each other, and it appeared better to consider the treatment necessary as a whole.

This is not the occasion to refer to the treatment of chronic ear discharges, which is a subject of itself more than long enough to occupy as much space as the present communication. The importance of maintaining a free exit for the discharges both from the Eustachian tube and the auditory meatus has been already urged. If the perforation in the drum-head is very small, it may be well in certain cases to enlarge it. My experience, moreover, with incision of the membrana tympani is such that I am convinced that many membranes which, left alone, would have become perforated or destroyed, have by a timely puncture been restored. It is not often easy to see a case at the best time for the incision, but I think it likely that in scarlet fever especially, if the ear complication is looked for and the membrane incised at the right moment, an exit will be given to the pent-up pus and in many cases the tympanic membrane saved, and this, it may be, at a time when the Eustachian tube is closed by the pharyngeal lesion and Politzerisation is rendered difficult or impossible. In a case of this kind which I saw with a medical man a year or two ago one membrane had perforated and the other seemed on the point of doing so. The latter was incised, and Politzer's bag used, and it was learned afterwards that speedy recovery ensued.

A few words as to the incision over the mastoid—Wilde's incision, as it is called, after the eminent Dublin surgeon. It is an operation generally recognised as of great value. In the last case related it was performed with the previous clear understanding that it was quite probable the mischief was in the interior of the bone, and that it was done to see the benefit the incision alone would render, and to obviate if possible the more serious procedure of opening the mastoid cells. No pus came away, and the beneficial result would appear to have been caused by relieving tension, by opening the periosteum and giving relief to the inflamed bone beneath. In cases in which the mastoid is tender the incision affords benefit. In the instances also mentioned here in which it was used it gave relief either by freeing pus or by giving a means of exit to suppuration in the bone. After making the incision it is a good plan to examine the condition of the bone; it may have already perforated, and the opening may be enlarged with a probe or other means, or it may be thinned and be readily penetrated by the knife. It is an interesting fact, attested by many surgeons, that chronic ear-discharges often cease after the mastoid process has been opened. The aperture, if large enough, is a convenient way for cleansing the tympanum by syringing through the latter. The condition of the mastoid bone itself must materially influence the inflammatory process set up in it. It is well known, for example, that the mastoid is absent in the new-born child, though Politzer in the first years of life has found it as a "considerable blunt protuberance." Then, as to its internal structure, it does not always consist of air-cells, but the interior may be often entirely or in part occupied by an adipose or compact osseous substance. Zuckerkandl[8] has pointed out that, among 250 temporal bones he examined 36·8 per cent. had the mastoid process entirely pneumatic; 43·2 per cent. partly pneumatic and partly like diploë; and in 20 per cent. it was composed of sclerosed osseous tissue. Politzer states that it is impossible to ascertain in a living person the anatomical condition of the mastoid, and it is only at the time of an operation in the process itself that its nature is revealed. Another point of moment is the varying forward position of the sigmoid fossa in which lies the lateral sinus, for this is of great importance in connexion with an operation for perforating the mastoid. Thus "Hartman[9] found in 100 cases, through the variable position of the sigmoid fossa, which appeared to be shifted forward to a considerable extent in many cases, as also through the middle cranial cavity lying lower than usual, the transverse sinus was wounded twice and the middle cranial cavity three times at the opening of the antrum mastoideum from without." In any operation, therefore, it is desirable to keep as far forwards as possible, making the incision at or just behind the attachment of the auricle. Politzer employs a second incision, prolonged backwards from the upper end of the first, forming in this way a flap. The direction subsequently for penetrating the bone and reaching the antrum mastoideum would be inwards, upwards, and forwards. For opening the bone a trephine has been used, and also a chisel, straight and hollow, with mallet, have been employed. I have generally gone to a case provided with these instruments, but I am disposed to adopt a perforator with a stop to regulate the necessary depth, such as Mr. Dalby has recently advocated. Left to themselves, cases of mastoid suppuration may perforate inwardly and set up meningitis, or, through the lateral sinus, thrombosis. At the same time there is a greater tendency to come outwards, and if timely aid is unsought, pus may burrow under the muscles of the head or neck and perforate at some distance. More or less caries often results, but it is not uncommon to see scars on the mastoid, the evidence of former disease, which has been recovered from.

In this practical review of the way the mastoid process becomes implicated many points have been necessarily omitted. Internal medication has thus received no proper notice, and I will only say that I believe sulphide of calcium, which in my hands has been such a satisfactory remedy in strumous ophthalmia,[10] will be found useful in chronic ear affections in scrofulous subjects.

ON A

METHOD OF CONTROLLING BLEEDING DURING COMPLETE OR PARTIAL EXCISION OF TONGUE.

BY JORDAN LLOYD, M.B., F.R.C.S.,
SURGEON TO QUEEN'S HOSPITAL, BIRMINGHAM.

I AM not about to inflict on the profession another mode of tongue removal. Too many operations for this purpose have already been devised and executed; several of them doubtless being excellent, and possessing certain advantages in particular cases. From amongst the whole number I should single out Kocher's probably as the best where the entire organ is to be eradicated; and in those very rare cases where unilateral excision only is called for, removal by the mouth with scissors as suggested by Whitehead (after splitting the organ as advised by Morrant Baker) is the plan to which I should give preference. I have no love for cauteries or écraseurs in tongue excision; they so frequently betray us by failing to realise the only advantage which can possibly be claimed for them—viz., the prevention of hæmorrhage. In all operations on the tongue bleeding has been the factor most difficult to combat. I believe that the procedure described below will reduce our trouble from this source to a mere trifle, for when it is properly carried out the tongue may be cut through at its root with knife or scissors without any blood loss whatever. Before attempting this procedure I would invite the surgeon to familiarise himself with the glosso-epiglottidean pouch, by palpation with an index finger introduced into its deepest part and another placed outside between the hyoid bone and the under surfaces of the angles and rami of the lower jaw. It is surprising how little tissue intervenes between the fingers, and how distinctly the various structures in relation to this space can be identified.

Chloroform having been administered, gag the mouth widely open, introduce the left index finger well to the bottom of the glosso-epiglottidean pouch, defining clearly the hyoid bone with its cornua, the front of the epiglottis, and the back of the root of the tongue. Take a stout, long, well-curved needle in handle, threaded with medium-sized whipcord, and enter it from the front of the neck in the middle line immediately above the hyoid bone; feel for the point of the needle with the left finger as the instrument is pushed through the root of the tongue. In this way the epiglottis is protected from injury, and nothing more than the lingual tissues are transfixed. Hook up the loop of thread with the left finger, and pull it well through and out of the mouth. Withdraw the needle, liberate the thread from it, and cut through the loop. Now enter the empty needle at the same point of puncture, through the skin only, and pass it subcutaneously—say to the right—until its point is opposite the upper border of the root of the great cornu. (This step is facilitated by pinching up the skin and pulling it outwards away from the needle.) Care must be taken that the needle runs immediately beneath the skin, so as to be outside and well away from the lingual artery. Now turn the point inwards above the great cornu, so as to enter the bottom of the side of the pouch, the finger having again been introduced to receive the point of the instrument. Thread one of the ends of the cord which is in the mouth through the needle and withdraw. A loop will in this way have been made around the root of the right half of the tongue; its two ends emerging from the median puncture are to be tied tightly enough to control circulation (best ascertained by feeling for the pulsation of the lingual vessel on the under surface of the tongue). A similar proceeding is to be carried out on the left side, and then the whole tongue will be secured in two separate halves. There is no real difficulty in the operation. The guiding finger in the pouch enables us to recognise all the structures concerned with the greatest confidence and accuracy. The only possible danger is that of passing the needle too far backwards in the second puncture, thus wounding one or other of the carotid arteries. I can only conceive this occurring in careless hands in very thick necks. Instead of entering the needle the second time at the first puncture, the surgeon may, if he chooses, make a fresh puncture altogether, at a point external to and immediately above the root of the great cornu, and may push the needle straight through into the pouch, thus avoiding the subcutaneous manipulation. The encircling ligature will then include the external skin between the points of puncture, which may slough if the ligature is pulled too tight or allowed to remain on too long. I have practised both methods, and have seen no bad effects follow. I have cut through tongues after the application of these ligatures with knife and with scissors, and in all my incisions have been absolutely bloodless. After the tongue is removed and the lingual arteries securely tied, the ligature of one side is to be liberated, and any bleeding points which then appear are to be tied; afterwards the other ligature is to be removed. When the median puncture only is made, as in the first method described, the loops must be cut through from the mouth by passing a blunt-pointed bistoury beneath them where they lie in the pouch. In the second method the loops must be cut through externally over the included skin. It is important to see that the threads are not twisted before beginning the second punctures, otherwise the loops engage the one in the other. This makes no difference to the efficient control of the circulation in both sides of the tongue collectively, but when the time comes to remove the threads the division of one will slacken the other, and thus liberate the smaller vessels in both sides at the same moment.

I first tried the above method on October 20th, 1883, and succeeded in completely removing a cancerous tongue without any loss of blood from the tongue tissue itself. In this case, after my ligatures, I performed Whitehead's operation with scissors. My last case was done a few weeks ago, on a patient sent to me by my friend Mr. T. Law Webb, of Ironbridge. I then removed the whole tongue within half an inch of the hyoid bone, without the loss of a single minim of blood from the lingual tissue until after the removal of the ligatures. So effectively was the circulation controlled that, when the tongue had been liberated from its lateral attachments, I cut it away with a single sweep of a bistoury, the stump remaining as dry as in an amputated limb surrounded with an Esmarch's ligature.

ALBUMINOMETRY AND ESBACH'S TUBES.

BY J. E. BLOMFIELD, B.A. OXON.,
RADCLIFFE TRAVELLING FELLOW.

THE usual method for the quantitative determination of albumen in the urine in the course of clinical work must be regarded by everyone as unsatisfactory. It consists generally, according to my experience, in boiling a test-tube about half filled with the urine, allowing the coagulated albumen to subside, and then getting by sight a rough estimate of the proportion of the albumen to the amount of urine employed, which must necessarily vary with the idea of the proportion according to the observer, where one person would call it an eighth, another would say a tenth, and so on. There is a method used as clinical routine in many of the French hospitals, which is in every way as convenient as this, but which yields results possessed of numeric accuracy, and which serves to give a good idea of the actual amount of albumen a patient is losing by his urine. The method was devised by Dr. Esbach, and consists in the precipitation of the albumen by means of picric acid. After standing twenty-four hours, the precipitated albumen reaches a certain height in the tube, and it is according to height to which it reaches that the amount of albumen is determined. The tube is empirically graduated in such a way that the number to which the precipitate reaches gives directly the grammes of albumen per litre of urine. The reagent for precipitation is made by dissolving ten grammes of picric acid and twenty grammes of citric acid in 800 or 900 c.c. of boiling water, and then adding sufficient water to make one litre. Urine is

Digitized by Google

poured into the tube up to a certain mark, the reagent added up to another mark, and then the tube is inverted about a dozen times to mingle well the contents, and placed in the vertical position for twenty-four hours, when the height to which the subsided precipitate has reached gives the grammes of albumen per litre. The tubes can be procured for three or four shillings from Brewes Frères, 43, Rue St. André des Arts, Paris.

KING'S COLLEGE HOSPITAL.

COMPOUND FRACTURE OF THE HUMERUS IMPLICATING THE ELBOW-JOINT; RECOVERY WITH USEFUL JOINT; REMARKS.

(Under the care of Sir JOSEPH LISTER, Bart.)

BEFORE the introduction of the system of antiseptic treatment, introduced and perfected by the surgeon having charge of this case, such an injury would most likely have resulted in the loss of the limb. Had the operator, taking into consideration the youth of the patient, attempted to save the arm, as was here done, the amount of dirt ground into the wound would have inevitably caused suppuration in and around the joint. This would have ended either in the performance of secondary amputation or in ankylosis of the elbow, supposing the patient to have escaped the danger of septic absorption to which he would have been exposed. In this case there was no suppuration, no pain during the after-treatment, and the usual movements were restored. The following notes are supplied by Mr. R. C. Priestley, house-surgeon.

James W——, aged sixteen, was admitted into the Victoria ward on August 9th, 1885, suffering from an injury received through his arm being caught between two revolving wheels of a machine. On admission there was found a lacerated wound three or four inches long on the outer side of the elbow-joint. The muscles arising from the outer condyle were exposed and lacerated, and the external condyle was separated from the shaft of the humerus, and lay loose in the wound; the ligaments about the elbow-joint were so much torn that the finger could be introduced between the articular surfaces of the humerus and ulna with ease. The forearm and exposed muscles were begrimed with machine oil, the whole wound being in a terrible state of dirt.

The patient was put under the influence of an anæsthetic about three hours after the accident. Some ordinary soap and carbolic lotion (1 in 20) were then mixed so as to form soapsuds, and the whole wound was thoroughly scrubbed with this by means of a clean nail-brush, until every trace of grease and dirt had disappeared. The fractured external condyle was removed, and loose tags of muscle were snipped off with scissors. The joint was syringed out with carbolic lotion (1 in 20), and a counter-opening was made over the internal condyle, through which a drainage-tube was introduced. No attempt was made to bring the edges of the wound together by sutures or otherwise. The arm was enveloped in an antiseptic dressing, and an angular splint applied. The wound healed without suppuration, and there was absolutely no pain. The temperature was normal, except on one occasion (the eleventh day), when it rose to 100·1°. Passive motion was begun early, and at the end of three weeks the joint permitted all the usual movements. The patient was discharged at the end of five weeks, cured.

Remarks.—The special points of interest attaching to this case are: the apparent hopelessness of trying to render the wound aseptic, owing to the infiltration of so much dirt and greasy material; and the success of the treatment adopted, as shown by the complete restoration of the joint to its usual functions.

BRADFORD INFIRMARY.

FUNCTIONAL DISEASE OF THE HEART; REMARKS.

(Under the care of Dr. H. C. MAJOR.)

FOR the following notes we are indebted to Mr. Eustace G. Carter, house-physician.

Richard B—— was admitted on October 28th (has been an in-patient five times during the last five years, under the late Dr. Tibbits), suffering from the same symptoms as when previously under observation. By occupation a blacksmith. Family history entirely satisfactory. Unmarried; suspicion of sexual excess. Has occasionally been drunk, the last time twelve months ago. Is not an excessive smoker. No history of acute rheumatism or illness of any importance up to five years ago, when he had for the first time an attack similar to the one about to be described, following a "bad cold." Five months ago he had "inflammation of the lungs" and was in bed three weeks, but had no symptoms referable to his heart during that time. He says that in one of the attacks mentioned above he "had swelling of the legs." One month ago a severe bilious attack left him suffering from dyspeptic symptoms—viz., flatulent eructations, acid taste in mouth, &c. Whilst suffering in this way palpitation suddenly set in, but was not worse on exertion; this gradually became more severe, obliging him to discontinue his work.

On admission, he was a fairly well developed young man, with well-marked general cyanosis; eyeballs rather prominent, but no enlargement of the thyroid gland. Dorsal decubitus was present (maintained throughout the attack). His whole body seemed to be shaken by the rapidity of the heart's action. Pulse 144, very weak; respiration 24; temperature normal. Complained of an "aching pain" across the lower part of the thorax. Thorax well formed; skin over præcordial and hepatic regions of a dark-brown colour, from frequent counter-irritation. There was a rapid, regular pulsation over the whole of the præcordial, hepatic, and epigastric regions, without thrill on palpation. Apex-beat of heart diffused, probably in fifth interspace, three inches and a half from the left edge of the sternum. Superficial cardiac dulness measured horizontally, opposite the fourth rib, three inches and a quarter, beginning at the left edge of the sternum; no increase of vertical dulness. On auscultation no bruit could be detected. Lungs clear. Abdomen distended; no bulging in flanks; hyper-resonant note in every area; violent pulsation in epigastrium and at hypochondriac regions. Hepatic dulness increased for about three-quarters of an inch; tongue furred; bowels confined; urine high-coloured, intensely acid, sp. gr. 1035, no albumen. Ordered ten minims of tincture of digitalis, with half a drachm of compound spirit of ammonia three times a day; milk diet.

Oct. 16th.—Passed a restless night. Complains of abdominal distension and choking sensation in his throat. Pulse now uncountable; heart sounds cannot be differentiated.

20th.—Continues in the same condition, though his symptoms are exaggerated. Cyanosis more marked. Has developed a harsh ringing cough. Is in an extremely excitable state, throwing himself about in bed and imploring relief. Vomits everything taken; says milk chokes him. Medicine stopped; ice-bag to præcordial region; ice to suck, and teaspoonful doses of Brand's essence of beef to be taken every hour.

21st.—8 P.M.: Pulse still uncountable; vomiting less frequent; is very much excited. A quarter of a grain of morphia injected.

22nd.—10 A.M.: Expresses himself as feeling much relieved. Pulse 82, full, yet dicrotic and intermittent. Heart: no bruit to be detected, but the pulmonary second sound is markedly accentuated. Has passed 86 oz. of urine in the last twenty-four hours.

24th.—Continues better. Passed 177 oz. of pale limpid urine in the last twenty-four hours. Heart-sounds clear and well struck; cyanosis less marked.

30th.—The superficial cardiac dulness is now normal; apex-beat also in normal position, and not now diffused. All pulsation in epigastric and hepatic regions gone. On auscultation, the accentuation of the pulmonary second sound has disappeared. Pulse 60, still dicrotic (dicrotism well shown in sphygmogram). Continues to pass from between sixty and seventy ounces of urine in the twenty-four hours.

Digitized by Google

Nov. 16th.—Up daily for the last fortnight; helps to make the beds, and has no symptoms whatever. Has had no medicine since Oct. 22nd, save purgatives occasionally. To be an out-patient.

Remarks by Dr. MAJOR.—When first seen on admission the diagnosis of organic disease of the heart was made, but on surveying the case as a whole, the weight of evidence is in favour of functional disease of that organ. I will therefore give shortly the evidence on either side. (*a*) Points in favour of organic disease: (1) Occupation (a blacksmith); (2) history of anasarca during a previous attack; (3) the obviously dilated condition of the heart when admitted; (4) the marked cyanosis. (*b*) Points in favour of functional disease: (1) No history of acute rheumatism; (2) suspicion of venereal excess; (3) attack not brought on by exertion; (4) absence of orthopnœa; (5) sudden onset of attack whilst digestion was disturbed; (6) no bruit to be detected, either during the height of the attack or when the heart had slowed down; (7) no symptoms of mechanical derangement of the circulation, save the dilatation of the heart and the cyanosis, the probable explanation of this latter symptom being over-action of the heart, due to some functional derangement of the cardio-inhibitory centre in the medulla; the heart, as it were, having "got the bit between its teeth," was galloping away from its driver, the pneumogastric nerve.

DUNDEE ROYAL INFIRMARY.

HYPERPYREXIA OCCURRING TWICE IN THE COURSE OF ACUTE RHEUMATISM; TEMPERATURE OF 110·4°; COLD BATHS; REDUCTION OF HEAT AFTER EACH; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. SINCLAIR.)

FOR the clinical record of the following case we are indebted to Mr. Malcolm A. Ker; and for the notes of the necropsy to Mr. A. M. Stalker.

John M——, aged fifty-five, shoemaker, was admitted into No. 12 ward of the Dundee Royal Infirmary on July 8th, 1885, suffering from an attack of acute rheumatism. For the last thirty years the patient has been very intemperate in his habits. Twenty years ago he was seized with an attack of acute rheumatism, ascribed by him to alternations of heat and cold which he was exposed to while at work. Since that time he has had numerous attacks, from which he always made good recoveries, being completely free from pain during the intervals. The present attack began about a week previous to admission, the joints of the upper extremities being affected first; later, the ankles, knees, and hips were involved.

State on admission.—The patient is a well-developed muscular man. Face flushed; skin hot and dry. Complains of pains in his ankles, knees, hip-joints, and right wrist, the knees being considerably swollen and imparting a feeling of fluctuation on palpation. Tongue thickly furred; appetite poor; bowels constipated. Pulse 112, of fair volume, but very compressible. Heart-sounds feeble, but pure. Physical signs of lungs normal. Temperature at 4 P.M., 102·8°. Ordered half a grain of extract of podophyllin and twenty grains of salicylate of soda every hour for three hours.

July 9th.—Temperature 100°. Urine acid in reaction; sp. gr. 1035; large deposit of urates; contains albumen. Salicylate of soda increased to twenty grains every hour for six hours. Evening temperature 100·2°. Pains much relieved to-night.

10th.—Temperature 99·6°. Swelling of knees gone. Still some pain in affected joints. Evening temperature 100°.

11th.—Temperature 101·4°. Patient states that he is quite free from pain. Salicylate of soda reduced to twenty grains every hour for four hours.—11.40 A.M.: Temperature 101·4°.—3 P.M.: Temperature 103·6°.; pulse 142, bounding; very compressible. Patient has a vacant, stupid look, and talks in a silly manner.—3.45 P.M.: Had twenty grains of antipyrin.—4.45 P.M.: Temperature 103·6°. Antipyrin repeated.—6.30 P.M.: Temperature 105°.—7.15 P.M.: Had twenty grains of sulphate of quinine.—9.20 P.M.: Temperature 104·2°. Patient is violently delirious. Put into strait jacket. Had one-third of a grain of hydrochlorate of morphia subcutaneously.—10.30 P.M.: Delirium has passed into a state of complete coma. Breathing stertorous.

12th.—12.15 A.M.: Temperature 107°. Pulse 150, full, compressible. Respiration 30 per minute.—1 A.M.: Temperature 108·2°.—1.30 A.M.: Temperature 108·8°. Radial pulse imperceptible. Heart-sounds almost inaudible. At this juncture patient was put into a bath at a temperature of 80° F., which was rapidly cooled down, by the addition of ice, to 50° F. The following tabular statement is an accurate record of the observations made at the time:—

Time.	Temp. of bath.	Temperature of patient per rectum.	Remarks.
A.M. 1.30	80°	108·8°	Patient placed in bath; radial pulse imperceptible; heart-sounds almost inaudible; complete coma.
1.35	80	110·4	Had enema of 2 oz. of brandy.
1.45	50	109·0	Enema repeated.
1.50	55	107·8	Pulse 140, perceptible at radial artery.
1.55	53	108·0	
2.5	53	102·8	Pulse 120, gaining strength.
2.10	55	102·0	
2.16	57	101·4	Pulse 124, taken out of bath.

2.16 A.M.: On being lifted out of the bath, the patient was rolled in a warm blanket, carried to bed, and rapidly dried. He was then transferred to another bed, surrounded by hot bottles, and covered by warm blankets. At 2.30 A.M., half an hour after removal from the bath, the temperature was normal; pulse 116, good; respiration 28 per minute; slight conjunctival reflex. During the next hour the temperature gradually sank to 95·2°, after which reaction set in and it began to rise. The following table shows the changes in the patient's state from the time of his removal from the first bath until he was immersed the second time:—

Time.	Temp.	Remarks.
A.M. 2.30	98·6°	Pulse 108, improving in strength; patient beginning to resist; slight rigor; had 1 oz. of hot coffee per rectum.
2.38	97·9	
3.0	96·0	Severe rigors; conjunctival reflex absent; pulse 100, very weak; enema of coffee repeated, but not retained; had hypodermic injection of 25 minims of ether.
3.30	95·2	
4.0	97·4	Pulse 112, improving; rigors gone.
4.30	98·2	Pulse 112.
5.0	99·8	Pulse 110.
5.30	100·6	Pulse 100.
6.0	101·6	Pulse 105.
6.30	101·8	Pulse 105.
7.0	103·0	Pulse 126, respiration 20; epiglottis falling back during inspiration; conjunctival reflex well marked; had hypodermic injection of 30 minims of ether.
7.30	103·2	Pulse 110; had enema of sulphate of quinine (30 grains); ice-bags to spine and head.
8.0	103·0	Pulse 110; respiration 30.
8.30	104·0	Pulse 120, very weak; had hypodermic injection of
9.0	104·6	30 minims of ether.
9.30	105·0	Pulse 116; patient has had an attack of severe bilious vomiting; over whole surface of chest numerous moist râles are heard; gurgling in trachea and large bronchi; frothy mucus flowing freely from nostrils and mouth; respiration 30, stertorous; cyanosis of face; patient was placed on his side, sinapism applied to front of chest, and turpentine stupes over the bases of the lungs.
10.0	106·0	Pulse 116; respiration 32, less laboured, gurgling less; had hypodermic injection of 30 minims of ether.
10.30	106·2	Pulse 109; after consultation it was agreed to repeat the former treatment, and the patient was accordingly transferred to a bath at a temperature of 90° F., which was rapidly cooled down to 56° F.

The following are the results of the treatment:—

Time.	Temp. of bath.	Temp. per rectum.	Pulse.	Remarks.
A.M. 11.0	90°	103·0°	108	Put into bath; complete coma; stertorous breathing.
11.5	66	103·0	108	
11.10	60	107·5	112	Had hypodermic injection of thirty minims of ether.
11.15	57	106·3	108	Slight movement of hands.
11.20	56	105·2	104	
11.25	58	103·9	108	Heart sounds very faint; had enema of 2 oz. of brandy.
11.30	59	—	96	Thermometer would not rise.
11.35	—	—	—	Taken out of bath.

At 11.35 A.M. the patient was removed from the bath, and underwent the same treatment as on the former occasion.

Digitized by Google

Five minutes later the temperature was 98·3°, pulse 84, and gaining strength.—11.40 A.M.: Had two ounces of brandy and one pint of beef-tea by the stomach-tube.—12 noon: Temperature 95°; pulse 100; respiration 100, laboured.—1 P.M.: Temperature 95°; pulse 105.—1.30 P.M.: Temperature 99°. Had hypodermic injection of thirty minims of ether.—2 P.M.: Temperature 101°; pulse 115.—2.30 P.M.: Temperature 101°; pulse 118. Ether repeated.—3 P.M.: Temperature 101·6°; pulse 120; respiration 30, more laboured.—3.10 P.M.: Numerous sibilant and moist râles heard over the whole chest; tracheal gurgling; no dulness over bases of lungs; frothy mucus flowing from the nose and mouth; great dyspnœa; cyanosis of the face remarked; pulse very weak.—3.20 P.M.: Had one-tenth of a grain of apomorphia subcutaneously; vomited immediately.—3.30 P.M.: Tracheal gurgling much less; dyspnœa diminished; pulse imperceptible.—3.50 P.M.: Died.

Necropsy, twenty hours after death.—On opening the thorax the lungs did not collapse. The pericardium did not contain any fluid. The substance of the heart presented a waxy appearance on section. The cavities were filled with decolourised blood-clot. All the valves were normal. Lungs: These were fairly crepitant throughout. On section a large quantity of serum could be expressed. The bronchi were injected. Abdomen: The liver, spleen, and kidneys were hyperæmic. Head: The brain was anæmic.

Remarks by Dr. SINCLAIR.—Hyperpyrexia is a complication of sufficient interest and rarity to justify the publication of every case. In the three years that have elapsed since the publication of my first case[1]—a successful one, occurring in the course of acute rheumatism—I have seen pronounced hyperpyrexia only three times: once it occurred in scarlet fever, once in puerperal pneumonia, and the third time in the case so well recorded above by Dr. Ker. The scarlet fever case occurred in the practice of Dr. Stewart, of Newport-on-Tay. The puerperal pneumonia case occurred in my own practice. In the latter I had the advantage of the advice and assistance of my neighbour, Dr. Macewen. Both, unfortunately, terminated fatally; but the power of the cold bath in reducing the temperature and improving the general condition was amply demonstrated in both cases. I was summoned to see the patient whose case is recorded above about 1 o'clock on the morning of July 12th last, and found that his temperature had been rising since 3 o'clock on the previous afternoon. When I arrived at the infirmary I was told that the patient had been going so steadily downhill since I was summoned half an hour previously that his case seemed hopeless; and indeed matters looked bad enough. The patient had a sunken aspect, was comatose, was breathing rapidly and stertorously, had no radial pulse, almost inaudible heart-sounds, and a temperature of 108·8°. But I had sufficient confidence in the value of the cold bath, derived from a perusal of the cases of Dr. Wilson Fox and others, and from my own personal experience, to think myself justified, even in such desperate circumstances, in giving the system a trial. Accordingly, everything necessary was instantly prepared, and the patient was a few minutes later, immersed in a bath at a temperature of 80°. An ample supply of ice was used, and the water was—with difficulty at first, I confess—cooled down to 50° F. Dr. Ker's admirable statements show most clearly the effect of the treatment in restoring the patient from a state of coma, an almost paralysed circulation, and a temperature of 110·4°, to a condition of restored circulation and a temperature of 101·4°. At a consultation in the forenoon it was decided, as the temperature had risen rapidly to 106·2°, to repeat the bath. Again in desperate circumstances the patient was immersed, and again the temperature was reduced. But, although the effects were very satisfactory for the first twenty-five minutes, in the next five minutes the body-heat fell from 103·9° to a subnormal point, and this in water which had actually gained three degrees in the preceding ten minutes. The patient was, of course, at once removed to bed, and again he rallied. But when I saw him again, about 3 o'clock in the afternoon, his respiration was so seriously embarrassed by the accumulation of bronchial exudation that I gave him one-tenth of a grain of apomorphia hypodermically. This certainly had the effect of emptying his stomach and the bronchial tubes, and consequently his dyspnœa was much relieved; but soon after his circulation failed and he died. Fatal though the result unfortunately was in this case, I think there can be no doubt of the soundness of the treatment. Before the immersion of the patient on both occasions he was evidently dying, and dying rapidly, from excessive heat. On both occasions the bath rescued him from imminent peril against which no other known therapeutic agent is of the slightest use. Had his tissues suffered less, or had he had more resisting power, the result might have been very different. But the lesson of the case is clear and certain: that in the external application of cold we have a remedy on which we can rely for the reduction of excessive temperature in the human body. I cannot conclude this note without expressing the gratitude which I feel for the invaluable aid I received during a very anxious time from my medical friends, and especially from Drs. Stalker, Mackie Whyte, and Ker. The nurses of the ward joined with these gentlemen in performing their trying duties with an energy and a loyalty which are beyond all praise.

PATHOLOGICAL SOCIETY OF LONDON.

Colloid Degeneration of Breast and Omentum.—Spontaneous Fracture of Urinary Calculi.—Diffuse Sclerosis of Brain in an Infant.—Large Aneurysms.—Post-nasal Fibroma in a Child.—Syphilitic Necrosis of Vomer.—Stricture of Rectum.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair.

Mr. EVE showed several Tumours with Colloid Degeneration. The first specimen was a tumour of the omentum removed from a man aged twenty-seven, whose illness lasted six months; there was some ascites. An operation for the removal of the tumour was performed by Mr. Lawson Tait. The tumour had a very flocculent appearance, and many sago-grain-like bodies were found therein. An alveolar structure, of which the spaces were filled with colloid material, was to be seen in sections; the glue-like material resulted from mucoid degeneration of the sarcomatous tissues, for spindle-shaped and other cells could be detected. The tumour was a myxosarcoma, and not colloid carcinoma. He also showed another myxosarcoma of the omentum, as well as a true colloid cancer of the omentum, secondary to cancer of the ovary. Another was a specimen of considerable enlargement of the omentum from tubercular disease, removed from a woman who was operated on for acute peritonitis. Three months later the patient died from tubercular peritonitis. Specimens of colloid cancer of the breast had been presented to the Royal College of Surgeons by Messrs. Hulke and Savory. The disease in one case had lasted three years; the patient was a female aged eighty. Operation had been completely successful. Under the microscope an anastomosis of columns of epithelial cells was seen, together with mucoid degeneration of the stroma, not of the cells. Some spheroidal bodies with concentric lamination were always found in the stroma; these were due to change in the connective tissue cells of the stroma, and were very abundant. They had been described as "colloid" bodies; reagents had no effect on them. They were examples of concentric lamination, occurring without the presence of inorganic or crystallisable salts. Carcinoma myxomatodes had been described by German authors, and Billroth had recorded a case of cholesteatoma of the breast, that Mr. Eve thought was of the same nature. In reply to Dr. Bristowe, he said that the first case of omental disease succumbed about the time of operation.

Mr. S. JONES showed many Urinary Calculi illustrating Spontaneous Fracture. The calculi were taken from the bladder of a gentleman, aged eighty-one, whose gall-bladder was also full of calculi. He had suffered for twenty years from rheumatic gout, and for the last seven years from passage of calculi per urethram. Extravasation of urine necessitated perineal section, and through the incision in the membraneous portion of the urethra a number of pieces of calculi were extracted. Ten days later the patient died, and in the bladder seven more or less complete calculi and eleven detached pieces were discovered. Mr. Jones considered that these calculi contained in their interior soft deposits of mucus, urate of ammonia, and phosphates, which by decomposition and development of gas led to fracture.

Digitized by Google

Dr. Bernays had found urate of ammonia and carbonate and phosphate of lime in some brownish material which occupied the radiate fissures in the stones.—Mr. H. H. CLUTTON said that his specimen differed in that the calculus broke up from causes acting on the outside.—Dr. W. M. ORD said the specimens shown illustrated two methods that appeared to him to be operative in the spontaneous disruption of calculi. In some cases no doubt Mr. Jones's suggestion held good. The influence of colloids on calculi was a very interesting subject, and Rainey had shown that spheres of carbonate and phosphate of lime deposited in a colloid when removed to a second colloid fluid became eroded by a sort of molecular disintegration, and this happened though the two colloids differed but slightly in nature. This kind of process probably explained the disintegration in Mr. Clutton's specimen. Dr. Ord had shown seven specimens illustrating erosions of calculi due to alterations in the media in which the calculi existed; it was necessary to suppose that the fluid in the bladder underwent some kind of change equivalent to the above-mentioned experimental alterations of Rainey.

Dr. HENRY ASHBY showed a Brain affected with Diffuse Sclerosis taken from a male infant aged twenty-two months. The chief phenomena observed were convulsions, want of power of hearing or vision, nystagmus, retraction of the head, rigidity of the right arm and less of the left, occasional stiffness of the legs, mouth always open, noisy respiration as from paresis of soft palate, constant groaning, "smacking" of lips, and difficult deglutition. He was watched from eight months of age till death. At the necropsy there was some external hydrocephalus; the arachnoid was thickened; the pia mater consisted of many enlarged and tortuous capillary arteries, and could be stripped off without lacerating the brain substance; the cerebrum was everywhere very firm and tough; the cerebellum was apparently normal. The want of development of convolutions and sulci was a marked feature. The Sylvian fissure was deeply cut, but there was no trace of the fissure of Rolando; the grooves branching from the Sylvian fissure were occupied by branches of the middle cerebral artery; the frontal lobes had a somewhat granular aspect; there was but little differentiation of grey from white matter as seen on section; the lateral ventricles were much dilated, as well as the descending cornua. The microscope showed that there were very few caudate cells left in the grey matter; and the latter had undergone an indurating process, though no actual fibrous tissue could be detected. The perivascular spaces were enlarged, and the vessels that enter the cerebral cortex were distended with blood. The pyramidal tracts were markedly atrophied, especially the left tract, above the medulla. There were also descending degenerations in the spinal cord. On section the internal capsule was seen to be of the usual white colour; the white substance occupied less space than usual, was indurated, and of a grey colour like the cortex.—Dr. THOMAS BARLOW said that the specimen would serve to elucidate some obscure points in the pathology of brain disease in children. He had investigated one very nearly like Dr. Ashby's specimen. It was the brain of a microcephalic child, in which the disease was of intra-uterine origin. The brain was very small, and differed in this from the specimen shown. The distribution of the meningitis was much the same as in Dr. Ashby's case. There were indications in places of convolutions having been partly formed. Calcareous particles were also detected scattered over the meninges. He regarded meningitis as one of the causes of sclerosis of the brain.—Dr. HALE WHITE asked what the condition of the pupils was, for the anatomical characters were much like those of general paralysis of the insane.—Dr. ASHBY replied that the pupils were unequal; the brain gave no marked signs of remains of a meningitis, and he was not certain of the mode of origin of the disease, though it might be syphilitic.

Mr. BARWELL exhibited specimens of a large Abdominal and Popliteal Aneurysm taken from a man. There were enlarged liver and granular kidneys. Treatment by compression was adopted for a time for the popliteal aneurysm. Later on, Mr. Barwell ligatured the femoral artery with an [illegible] ligature. The abdominal aneurysm weighed seven pounds; it had eroded the vertebræ from the eleventh dorsal to the second lumbar; the aneurysm also pressed upon the kidneys and pleura. It was filled with laminated clot, but was traversed by a channel through which the blood flowed.

[illegible] showed a specimen of Post-nasal Fibroma removed from a boy aged eight years and a half. It was attached by a pedicle apparently to the upper surface of the velum palati, and had two digital processes, one of which was prolonged into each nostril. It hung in a pendulous manner over the upper opening of the larynx, and apparently had prevented the full development of the child. A fine reticulum of delicate fibrous bands, with some mucous tissue, was seen in sections; the myxomatous character was most marked in the processes above mentioned. He also showed specimens of (congenital) Syphilitic Necrosis of the Vomer, taken from a boy aged ten years; the fragments of bone were passed at intervals of some months. The syphilitic evidence was undeniable. Interstitial keratitis, fissures at the angles of the mouth, and pegged teeth could be seen now in the boy, who was also shown.—Mr. H. T. BUTLIN said the first specimen appeared to him to be undoubtedly myxomatous; it probably had grown from one of the turbinate bones; it was a very large mucous polyp, containing a mixture of mucous and fibrous tissues.

Mr. HARRISON CRIPPS exhibited a specimen of Tubular Stricture of the Rectum. The patient was a female, aged thirty-two, who suffered after parturition from pelvic cellulitis, and some pus had been passed from the bowel. After getting about, some difficulty in passing motions came on. On admission to the hospital emaciation and albuminuria were noted, and the patient was extremely ill. The operation of colotomy was followed in a week by death. There was a tubular stricture about five inches in length, commencing three inches from the anus. He observed great hypertrophy of the circular muscular coat, which was due to dense fibrous tissue. The origin of the disease was evidenced by the presence in the bottom of Douglas's pouch of a cicatrix, which had caused a bend in the rectum, and was the starting-point of the stricture. He did not think that a majority of these cases of rectal stricture in women were due to syphilis; but many of them owned a cellulitic origin. It was extremely rare in men, being ten times more frequent in women; whereas syphilis was far more common in men. He considered that this fact militated against the view that such cases were of syphilitic origin. They began as annular strictures; the consequent ulceration led to infiltration of the muscular coat, and so to a tubular constriction.

Mr. BRUCE CLARKE brought forward a specimen of Rectal Stricture of undoubted syphilitic origin. The patient had suffered from stricture for four years. Colotomy was performed, and four days later death ensued. Emaciation and albuminuria were marked symptoms. Palpation of the rectum showed the disease to be of cartilaginous consistence. There was hardening of both longitudinal and circular muscular coats, and this was especially marked four inches from the anus, where the stricture commenced. There was a total absence of epithelium, but in the submucous and muscular coats enormous numbers of small round cells had replaced largely the normal tissue. Some small round cells were also seen in the internal coat of the artery.—Mr. EVE said there was in the museum of the Royal College of Surgeons a Hunterian specimen of stricture of the rectum composed almost exclusively of hypertrophy of the muscular coats, and believed to be due to spasm.

The following card specimens were shown:—Mr. Eve: (1) Dislocation of Hip of Cow; (2) for Mr. A. Lingard, Specimens of Actinomycosis in Ox-en. Mr. Clutton: Spontaneous Fracture of Urinary Calculi. Mr. Churchill: Syphilitic Necrosis of Vomer (living specimen). Dr. Goodhart, for Dr. Marshall: Calculus in Bladder of Female Child aged two years. Mr. J. B. Sutton: Congenital Inguinal Hernia in a Monkey. Mr. H. Fenwick: Fibromyxosarcoma of Bladder. Dr. Hadden: (1) Lipæmic Blood in Diabetes; (2) Mucous Cyst of Tongue; (3) Gumma pressing on Ureter. Mr. J. H. Morgan: Double Dislocation (? Congenital) of Hip-joints.

MEDICAL SOCIETY OF LONDON.

Moot Points in Syphilis.

AT the meeting of this Society held on Monday last, Dr. W. M. Ord, President, in the chair, Mr. JONATHAN HUTCHINSON, F.R.S., read his second Lettsomian Lecture on some Moot Points in Syphilis.

The lecturer first considered the relationship between secondary and tertiary phenomena. It has been supposed that the viscera and nervous system suffer only in the

Digitized by Google

tertiary period, and that in the latter stage there is a general tendency to ulceration and to deep extension, which is not observed in the secondary one. "Gumma" has been supposed to be characteristic of the tertiary stage. But opinions on these matters have changed. It has been argued that syphilis may be very severe and run through some of its late stages before it has finished its first. By degrees, however, we are arriving at another interpretation of these facts, and are beginning to perceive that the old classifications of the phenomena cannot hold their ground, and that we must seek for other characters by which to distinguish the secondary and tertiary stages—not, indeed, that the old observations were wholly wrong.

Cases were given in illustration of the circumstance that gummata may occur in the internal viscera, certainly within the "secondary" stage of the disease. In the adult it is an every-day occurrence to observe symptoms implying periostitis, transitory disease of the nervous system, or even visceral affections during the secondary period. It is not so much in the special location, or even the character of the morbid changes, as in their boundaries, that we observe a difference between them and the lesions of the tertiary stage. The gummata of the early period are small and numerous; those of the later one are large, and often few in number, or even single. Those of the early period easily disappear either spontaneously or under mild specific treatment, whilst those of the tertiary stage persist and grow indefinitely unless adequately met. Hence it may easily happen that the indications of internal disease in the secondary stage may often pass unnoticed, whilst those of the later one rarely escape discovery. This point was argued more in detail in reference to two special lesions which, as they occur in parts open to inspection, are not liable to the fallacies that attach to speculations on lesions of the internal viscera—rupia and periostitis. Rupia is claimed as a definite tertiary symptom, but Mr. Hutchinson contended that this was a mistake. It almost invariably begins within a year of the chancre, and often much earlier. Everything that ulcerates is not necessarily tertiary. Rupia was defined as of bullous origin and tending to the production of conical crusts. It is never one of the earliest lesions, but occurs after erythematous and papular eruptions have disappeared. Often there has been an interval of good health, and all treatment has been laid aside. Sometimes the rupia happens apparently as a consequence of neglect of treatment. Very often a peculiarity in the diathesis of the patient has been implied by the fact that his chancre inflamed and ulcerated. Sometimes a papular eruption is converted into an ulcerating or rupial one by too vigorous treatment. A "scar-leaving" eruption often follows a "scar-leaving" chancre. The belief that the occurrence of rupia or other ulcerating eruption makes it desirable to avoid mercury and use only iodide of potassium is, Mr. Hutchinson thought, fast losing its hold. But it is really a question of *dose*. A condition allied to rupia, which is also something like lupus, is likewise met with; the round form of the sore is lost, for the inflammation spreads at its edges by local infection and allows of healing in the centre; thus a horseshoe form is assumed. This lesion may last indefinitely, unless carefully treated. It seldom originates *de novo* as a genuine tertiary; but it is more commonly a sort of continuation of an imperfectly treated eruption of early date. It ceases to be a generalised eruption, is no longer arranged with any tendency to symmetry, and is often more amenable to local than internal treatment. Mr. Hutchinson thought we might with justice speak of syphilitic lupus just as we had syphilitic psoriasis and syphilitic lichen. They are the syphilitic imitations of the type-malady. The most acute and rapidly destructive of syphilitic lupus is what has been termed erosive lupus, an almost phagedænic affection, which usually attacks the nose, and which is more frequently seen in inherited than in acquired syphilis. As a rule all lupoid affections rank as tertiary, and it would scarcely be too bold a generalisation to say that all the tertiary affections of the skin are of a lupoid character; by which is meant that they are all serpiginous, asymmetrically arranged, and all leave scars. The time for roseola, psorasis lichen, and even rupia, is past; and if the skin at this stage suffers at all, it will form a tubercular affection, which creeps at its edges, persists indefinitely unless cured by treatment, and leaves scars. It is, in fact, a serpiginous gumma of the skin. This generalisation is a most important one, as giving a clue to the character of the hidden affections of the deeper parts which occur in this stage. They, like lupus, may be serpiginous, the cell growth tending to infect the edge of the patch and thus cause persistent spreading. Such a pathological hypothesis would explain the phenomena of ophthalmoplegia externa, in which there are indications of slowly spreading central disorganisation. Locomotor ataxy may be regarded in the same light.

Periostitis may be secondary as well as tertiary. The nervous system may be attacked within the first year—e.g., neuro-retinitis, sensory disturbances, paraplegia, cerebral paralysis, also inflammation of the internal ear. The first attack of choroiditis disseminata often occurs within the first eighteen months; the pia mater might be inferred to be affected with similar changes. Mercury, if it does not cure, usually delays and retards symptoms, and so what would be secondary becomes tertiary in time owing to treatment. Mr. Hutchinson thought that it was quite impossible to classify secondary and tertiary symptoms into two groups with reference to the tissues that are attacked. We must thoroughly understand that there is no lesion which may not happen and no tissue which may not be attacked during the secondary stage. Everything that is tertiary is local in a sense which is not true of any of the secondary phenomena. The difference between secondary and tertiary eruptions of the same tissues was illustrated by what happens in the case of the palm of the hand and of the tongue. The relation of syphilis to locomotor ataxy was discussed, and Mr. Hutchinson was of opinion that syphilis predisposed to the nervous disease. Another moot point is the relation of syphilis to the specifics used in its treatment. The claim of mercury to rank as an antidote is strengthened by the recent experience of the antiseptic power of weak solutions of corrosive sublimate as well as by other considerations.

Mr. Hutchinson stated his own rules of practice. He employs grey powder in one-grain doses three to six times a day, prolonged over a period of six months. Respecting the results of treatment in general, he asserted that he had never in any single case of late years seen a severe eruption on the skin develop itself after a mercurial course of the kind indicated. It is a fact that mercury manifests antidotal power in that it can not only remove but anticipate and prevent by far the most conspicuous manifestations of the disease. He could not make so strong an assertion respecting some other of the symptoms of the later part of the secondary stage. It is a question of some interest whether syphilis has any tendency to develop itself by, so to speak, a series of successive waves. The observed phenomena may, however, be connected with the intermittent employment of antidotal treatment. Some cases of rupia, the worst that could be seen, were met with under such conditions; the patient having been cured of a first and much milder outbreak of eruption, and then after an interval of some months becoming the subject of a more severe one.

In conclusion, Mr. Hutchinson said that if his argument held good, we must regard the terms secondary and tertiary as applicable to different periods of time, and not to different phenomena. At the same time, it had been fully admitted that syphilitic processes do display different tendencies in relation with the stage in which they occur. The position assigned to tertiary symptoms has been that of late relapses of morbid processes in tissues previously damaged. In this way it has been suggested that syphilis may occupy an important part in predisposing to such maladies as locomotor ataxy, without actually causing them.

ACADEMY OF MEDICINE IN IRELAND.

The Surgery of the Soakim Expedition.—Organisation of the Medical Department of an Army Corps.

AT a meeting of the Surgical section on Dec. 11th, 1885, Mr. TOBIN, late of the Army Medical Department, read a paper on the Surgery of the Suakim Expedition. He explained the nature of the appointment styled "field surgeon" (which was that held at Suakim by himself), and pointed out the necessity for its being made a recognised appointment and its duties defined by the regulations. The statistics of the expedition were given, from which it appeared that of 129 wounded 124 recovered, or 97 per cent. Having exhibited a femur fractured by a rifle bullet at a point remote from that struck, the author pointed out the great difference noticed during the campaign between

Digitized by Google

wounds from the Martini-Henry and Remington rifles, and cited cases in point. By referring to the experiments of Professor Longmore, he showed that those on the dead body afford a reliable means of ascertaining the effects of gunshot wounds on living tissues, and that therefore the extension of such experiments was a desideratum.—Mr. WHEELER said there was a great advantage in having a surgeon who is in the habit of operating accredited to the army on active service. Billroth was attached to the German army during the Franco-Prussian war. He had the local rank of Surgeon-General, and was probably as well paid as most Germans. But if the British taxpayer desired the advantage of such aid for the British army in the field, he would not only have to pay largely the civil surgeon attached to the army, but make provision for his family should anything untoward happen to him. The statistics of the mortality of the wounded were most creditable, of 129 wounded only five deaths being recorded; and from the nature of the wounds of the five fatal cases it would have been almost impossible to save life. This very small mortality was due partly to the excellent care which was always afforded to the British soldier by the Army Medical Department, and partly to the very easy transport, the hospital where the operations took place being only about three miles from the seat of action, where the wounded were conveyed by dhoolies. The climatic influences, of which he had personal knowledge (having served some years ago in the country), were combated by shipping the patients as fast as possible and getting them away to sea. There was also drainage well established in every case, the necessity for which in wounds and after operations had been first definitely laid down by the late Mr. Callender. Moreover, there was easy transport in the Egyptian campaign, the wounded having been conveyed by water from Kassassin. The specimen of the femur exhibited by Surgeon-Major Tobin was unique. He was not aware of any recorded case of a fracture several inches away from where the ball struck. It was evident the ball had grooved the bone between the trochanters, causing splintering, but a fracture of the bone had taken place several inches below the neck of the bone. Dupuytren had written on the splintering of bone, classifying the splinters, and emphasising the impropriety of removing splinters indiscriminately. Professor Longmore's experiments, which Mr. Tobin had alluded to, were exceedingly valuable. The differences in the wounds produced by the bullets from the Martini-Henry and the Remington rifles would be accounted for by the great difference in the charge of powder.—Dr. BENNETT valued the communication as showing that much more conservative surgery might be adopted in the treatment of gunshot wounds than had been hitherto the rule. So, where a rifle bullet passed through the shaft of a bone tolerably near a joint, or even remote from it, they were not to conclude that there would be longitudinal splintering into the joint necessitating the amputation of the limb. The immunity which had been pointed out followed from the success of the antiseptic treatment.—Dr. BAXTER mentioned that in his experience of the Franco-Prussian war the percentage of recoveries was very good, though not so large as Mr. Tobin had recorded. Antiseptic dressings were never used. Ether was the anæsthetic.—Mr. TOBIN replied. In reference to Dr. Bennett's remark on the fissuring of the bones, the experiments of Professor Longmore showed that when bullets were fired into long bones the fissuring was often carried down to the capsule of the joint, the synovial cavity being opened into. By rough handling the fissuring would extend into it, but with care the wound was rendered non-penetrating. He thought that cleanliness could not be better arrived at than by carrying out the idea which had got the name of "Listerism." In his operations, a long anterior flap, if easily cut, was the one he found most suitable, as falling over the wound like the cover of a box, letting it go on healing, whether dressed or not, and therefore obviating the necessity of frequent dressings.

Surgeon-Major EVATT delivered an address on the Organisation of the Medical Department in an English Army Corps, with suggestions as to Volunteer aid. He said that civil doctors generally knew nothing of our army system of work, and both sections of the profession suffered in consequence. The army surgeon had developed ambulance aid to a point far beyond average civil arrangements, and the systematic training of the students in this work would be useful to all civil doctors. The medical service of the army had worked out a very logical system of hospital administration, based on the principle that the trained medical officer was the best fitted individual to be governor and director, as well as scientific head. Civil doctors, as a rule, had little power in their hospitals, and the students received no training in administration; yet it was a highly important matter, as hospitals went to grief constantly, not from defective science in surgery, but from bad nursing, bad construction, bad drainage, want of discipline and supervision—yet in none of these heads were the students trained. He then explained the war system of the army corps, showing on a diagram the battalion aid, the bearer companies, the field hospitals, the hospitals on the communications, the base hospitals, and the hospital ships, and traced the course of the wounded soldier from the battle-field back again to Dublin. He then said that, with the new duties undertaken by the medical service of the army, no change had been made in the student's training. No training for enforcing discipline had been given to the student, and no teaching in ambulance aid or in hospital administration had as yet been made part of the student's course. He suggested that the students should, as a matter of routine, be exercised in ambulance drill; secondly, that definite teaching in hospital administration should be given them—viz., in cooking, nursing, *personnel*, construction, ventilation, and drainage; and, thirdly, that residences for students were highly desirable in connexion with the medical schools, to improve the discipline of the student and his social comfort.—Mr. CANTLIE, of Charing-cross Hospital, London, advocated the importance of bringing civil surgeons into "touch" with the Army Medical Department by the means which Surgeon-Surgeon Evatt had suggested, and stated that he had himself organised a volunteer corps of medical students.—Dr. BARTON considered the advantage of the training to medical students would be very great, but, while willing to join in the project, felt unable to decide at once as to its practicability.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Extra-uterine Fœtation.—Pseudo-hypertrophic Paralysis.—Progressive Muscular Atrophy.—Inflammation of Tibia.

AT the meeting on Dec. 3rd, 1885,

Mr. C. ATKIN showed a specimen of Extra-uterine Fœtation, the rupture of which had caused death in sixteen hours. The woman was thirty-two years of age, and it was her fifth pregnancy. The menstrual flow was noticed a week before and on the morning of her death. Her symptoms led the druggist who was called in to treat her for poisoning. Mr. Atkin laid stress on the importance of diagnosing internal hæmorrhage, and the urgent necessity of operative interference in such cases, cold and hæmostatics being perfectly useless.

Mr. D. DYSON related two cases of Pseudo-hypertrophic Paralysis. The first patient exhibited was a boy aged eleven, who had had symptoms since the age of five. Measles and scarlet fever were the supposed causes. The gait, attitude, mode of getting up from the floor, and enlargement of calves and buttocks were characteristic. The progress of the case had been slowly downwards, notwithstanding the treatment consisted of electricity, nerve tonics, and exercise. The other case, a boy aged twelve, was a more advanced one. Heredity was a factor in the causation. He was now unable to stand, and there was much atrophy about the upper extremities. The same treatment as in the first case was of no avail. In both instances the mental condition was very good.

Dr. PORTER exhibited a case of Progressive Muscular Atrophy, of which the chief features were atrophy beginning in the muscles of both shoulders and both scapulæ, wing-like projection of the scapulæ, lordosis, coldness, and blueness of the hands, the temperature of the surface over the affected deltoids being 4° F. lower than that of the axilla or mouth. Latterly the hands had begun to assume the "main en griffe" form. Speaking of the lordosis, Dr. Porter said that Duchenne had described two varieties of curve in the spine, differing according as to whether the extensors or flexors of the trunk were principally involved. The case before the Society seemed to bear out this view as to the causation of the lordosis. The curve resembled the variety attributed by Duchenne to atrophy of the flexor muscles, and, whereas the patient could recover the erect posture after stooping, he was unable to rise from a recumbent to a sitting posture,

Digitized by Google

owing to failure in the flexor muscles. Dr. Porter alluded to the absence of the characteristic fibrillary contractions in his case, and stated that such was the case in at least one-fifth of those suffering from the disease.

Dr. GWYNNE showed a Tibia which had become the subject of osteitis some twenty years ago, and from which a sequestrum of bone six inches long had been removed. Two other pieces of dead bone, about three inches long, had been subsequently removed. The sinuses, after discharging more or less for five years, gradually closed up, leaving a fairly useful limb for about fifteen years. The patient (a woman), afterwards getting into low health through nursing weakly children, became subject to severe attacks of periostitis, with intense pain, which necessitated amputation, which was performed through the condyles of the femur. The specimen showed most of the shaft to be formed of dense callus, with obliteration of the central canal. The bone was abnormally thick, and there was a small sequestrum of dead bone, about two-thirds of an inch long, occupying its centre.

Mr. SNELL introduced a patient with double third nerve palsy, associated with contracted pupils.

Reviews and Notices of Books.

The Cyclopædia of India and of Eastern and Southern Asia, Commercial, Industrial, and Scientific. Third Edition. By Surgeon-General EDWARD BALFOUR. Three Volumes. London: Bernard Quaritch. 1885.

AT a time like the present, when the air is full of the signs of changes consequent upon a widening of the representative basis of our Government, and when that Government will be urged by forces resulting from the opinions and the energies of masses of people, it is of the greatest national consequence that a competent knowledge of our magnificent Eastern Empire should be spread amongst the population of this country. For if anything can steady the forces which govern, and prudently influence them too, a contemplation of the magnitude of the responsibilities which the Crown and the people of this kingdom have resting upon them with respect to India is that very thing. A fairly comprehensive knowledge of that great country, with its more than 200 millions of people, is now probably possessed only by a comparatively few cultivated men—men who have gained it by long residence in the East, or who have enjoyed much leisure, and have had at the same time access to the works of a variety of well-selected authors, which they have diligently studied. But this is now altered; for these three clearly printed volumes, which open so neatly, and which are so handy in size, contain more than all that is necessary for a clear and comprehensive knowledge of India and of Indian affairs.

In any cyclopædia, the articles of most interest will vary much with the occupation of its readers; and in this Cyclopædia of the East, the consulter of its pages, whether he be statesman, *savant*, civilian, soldier, or merchant, will find a succinct and wonderful store of information to answer his purpose and to fit him to draw well-based conclusions.

The book contains a good general index; but, besides this, there are three articles in the work each provided with an index of its own. These articles are: "Insects," "Mammalia," and the one with which we commence our short criticisms—viz., "India." The article "India" is properly the fullest in the work, and occupies nearly 200 pages. Here the author, after tracing the ancient history of the country, goes into its relations with her neighbours. Then he takes its provinces and deals successively with them, giving in well-arranged order, as he passes on, such general and particular information about its population and its resources as will satisfy the expectations of those who know the office of a book of reference like this. The article upon "British India" conveys a vast amount of information. The leading features of its history and progress are well brought out. With reference to these two articles, it appears to us that if printed and published apart from the rest of the work, with any additions or alterations which may commend themselves to the author, there are many of the more thoughtful of the reading public who, unable to purchase the entire work, will be glad to possess themselves of this *brochure*. But, if our suggestion be taken, we should like to see the book contain a map, if only in broad outline, to facilitate the study of the reader.

A comprehensive account of the mode of life of the Chinese people, of their government, of important things relating to trade, religion, &c., is given under "China." A person wholly ignorant of the country would get a very full general acquaintance with that little-understood empire from a perusal of this article. We note, however, that when referring to the comparative value of money, no account is taken of the fall in the price of silver. And we also note that in giving the derivation of the word "tea," it is stated to come from "te"; but we would suggest whether it does not rather come from the Chinese word "chaa," or "tsaa." But the article as a whole is a remarkably good one. There is a good article, too, upon "Salt," a commodity of the first importance to the people of India, and to the Government also, for it produces a revenue of no less than 7,000,000 sterling. It strikes us, also, that what is said under "Forests" is not only interesting, but that it has a value which will be better appreciated the more it is considered. For men have had too long a destructive bias towards the finest specimens of the vegetable world. In our own country, the general mischief as well as the pecuniary loss occasioned upon large estates (and upon many smaller ones too) by a want of attention to the science of forestry is patent to all who understand this important subject. In America, the quick accumulation of money has already been the cause of depriving enormous tracts of the northern continent of its most valuable timber; and the ill consequences of this pitiless destruction are beginning to be keenly felt. The art of forestry is akin with the daily duties of the medical man; for how much poor growth in both the animal and the vegetable world is due to unsuitable soil and surroundings! Much timber is stunted through overcrowding, with its attendant deficiencies of light and air, and by insufficient or unsuitable nourishment. The account given by Surgeon-General Balfour of the area of the forests and the character of the timber in the different parts of India is full of interesting facts. The subject of opium is well dealt with; its mode of preparation in different parts of the East is gone into, and the practice of opium-smoking is philosophically considered upon facts ascertained with painstaking care. The article as a whole is very interesting, and it deserves and will repay a careful and deliberate consideration. In fact, whether the author is dealing with general statistics and details of history and geography, or with philosophy, religion, science, or the industrial arts, the information is good; and care has been taken to keep pace with the latest authorities. The articles "Architecture," "Temples," "Cave Temples," "Hindú Sacrifice," "Stone Worship" and "Serpent Worship," "Education," "Rajputs," "Caste," and "Famines" are all excellent, and will well repay careful perusal. We think the biographical notices very good also, but in some important instances they are too contracted. Notices of such men as the two Lawrences should, we think, have been longer; so also should that of Outram, the two Muirs, Bentinck, Strachey, and the two Elphinstones. There are some, on the other hand, which are far too long in comparison. The revenue system of India scarcely receives adequate notice. We observe also that there are some short articles of great value subsidiary to others of a more general character, and yet no reference to them

Digitized by Google

is made. Had this been done, the student would more certainly secure to himself the information which the book contains upon a given subject. Take "Architecture" for example. A reference at the end of the article to Fatehpur Sikri, Agra, Delhi, Sarnath, and many others, would lead the reader to points of interest which might be missed from ignorance of particular localities, and the author would have been more just to himself, for his book is fuller of excellent matter than would readily appear.

We observe repetition also here and there. For example, under "Buddhist Architectural Remains," a description at some length is given of several caves—which, by the bye, are avowedly not Buddhist remains at all,—while the same information appears again a little further on under "Cave Temples," its legitimate place. Then in the science of botany, under the common name "Banyan Tree," particulars are given which appear again under "Ficus Indica." And what appears under the common name "Deodar," might have been given, with the particulars under "Cedrus Deodara," with a reference from one to the other. The same remark applies to "Flax" and "Linum Usitatissimum," and to other cases which might be mentioned. We notice, too, an account of the Siwalik Hills in three places—under (1) "Mountains," (2) "Himalayas," and (3) "Siwalik Hills." And we do not see that the articles entitled "Violin," "Socrates," "Cairo," "Kamtschatka," "Cachalot," "Luxor," and some others, have any claim to appear in this work. But, after all, what are these things when set against the real merits of this welcome and admirable addition to British reference literature?

We have not space to write as fully as we should like about these three volumes; but they make an addition to our standard works which can hardly be too highly valued, both because of their intrinsic merit and because they stand alone, so far as we are aware, making a storehouse full of important information possessed by but few people. The purpose of the work, and its character, alike indicate its place to be on the shelves of every public collection of books. So also should it be in the library, whether large or small, of everyone who wishes to possess a sound general and particular account of India and the East. The investment is indubitably a good one, for a share in the rich fruits of the author's indefatigable labours is more than a return for the expenditure required. And we heartily commend the volumes as an addition to the library of every medical man.

OUR LIBRARY TABLE.

American Gynæcological Transactions. 1884. New York: Appleton and Co.—This volume contains thirteen papers, the great majority of which are of considerable interest and value. With the exception of four, all of them discuss questions of treatment, seven dealing with abdominal section, directly or indirectly. It is a curious and not a very promising fact that so much attention should be paid to the end to be attained in medical science, while so little is done towards attaining that end by studying the processes of disease. There are some papers which deserve special mention, as Reeve on some Moot Points in regard to Inversion of the Uterus. The author ingeniously argues that inversion may begin at the cervix and extend gradually to the fundus, and brings some, but not conclusive, evidence in support of his view. Dr. Wilkie, in a paper on Foreign Bodies left in the Abdomen after Laparotomy, gives an account of some cases in which portions of sponge have been left in the peritoneal cavity, and of the methods employed by different operators with a view to avoid this accident. Lusk contributes a valuable note on the Ring of Bandl; and Thomas a further report on Extra-uterine Pregnancy. The President, in his address, discusses the present aspect of Puerperal Diseases. In it he has referred to American gynæcological literature in a way which will command the approbation of every right-thinking man. The distinct and emphatic condemnation of the mode in which certain subjects have been treated, pronounced by such an authority from the chair of the Gynæcological Association, cannot fail to have a beneficial effect, and will tend to raise the standard of both literature and practice.

Ringworm: its Diagnosis and Treatment. By ALDER SMITH, M.B. Lond., F.R.C.S., Resident Medical Officer, Christ's Hospital, London. Third Edition, Revised and in part re-written, with illustrations. London: Lewis. 1885.—This book, originating in our own columns, is too well established in the favour of the profession for us to do more than express our satisfaction at the appearance of a third edition, with important additions on the history of the disease and of the fungus which underlies it. It is admirably practical in its character, both as regards questions of diagnosis and treatment, and every medical man should have it in his library. We have only one critical remark to make, and that is on the portentous growth of parasiticides. They seem to multiply faster than parasites, and yet Dr. Smith's book is a proof of the superiority of these little troublesome organisms to nearly all the poisons that can be heaped on them, so that in even skilled hands it still takes months or even years to effect a cure. We must hope for a speedy announcement of the great simplification of this class of remedies, which at present are decidedly more numerous than effective.

Report of a Committee of the Clinical Society of London, nominated Nov. 10th, 1882, to investigate Spina Bifida and its Treatment by the Injection of Dr. Morton's Iodo-glycerine Solution. Reprinted from Vol. 18 of the Clinical Society's Transactions.—We have received from the Council of the Clinical Society a reprint of the Report of the "Spina Bifida" Committee. We understand that the special reason why this Report has been issued in a separate form is that the Council of the Society may present a copy to each of the gentlemen who contributed to it by sending details of cases or specimens of spina bifida. In this the Council has made an excellent precedent, and it would no doubt encourage others to aid in joint-works of this kind if it were the custom to present each contributor with a copy of the report when issued. Of the merits of this particular Report we have already spoken. We regard it as the most valuable yet issued by the Clinical Society. The pathological section has been very carefully done, and the long and full tables of cases in the clinical section, as well as the comments upon them, are of lasting practical value. The reprint of the Report is not for sale.

Die Chirurgischen Anatomie in ihrer Beziehung zur Chirurgischen Diagnostik, Pathologie, und Therapie. Ein Handbuch für Studirende und Aerzte. Von Prof. Dr. MAX SCHULLER, in Berlin. Heft I.: Die Obere Extremität. Mit zahlreichen Holzschnitten. Berlin: G. Reimer. 1885.—This is the first instalment of the most complete work on surgical anatomy that has yet been prepared. Not only each region but every section of each region is described with the utmost care and precision, and all the practical surgical bearings of the various anatomical details are pointed out. Muscles, vessels, nerves, and fasciæ are treated with the same detail and thoroughness, and their connexion with operations, inflammations, and deformities are fully discussed. The work is of great value, and we shall anxiously await the publication of the remaining parts.

LONDON WATER-SUPPLY.—By the East London Water Company's Bill power is granted to raise £300,000 to meet the increased demand for water within their district.

REGINA v. TURNBULL AND NOTTAGE.

AT the Central Criminal Court on Friday, Jan. 15th, William Turnbull, aged sixty, surgeon, and Mary Nottage, aged forty, midwife, were convicted of the manslaughter of Charlotte Louisa Clifford, aged eighteen, by unskilful treatment and criminal negligence; and on the following day were sentenced respectively by the Hon. Mr. Justice Denman to ten years' penal servitude and eighteen months' imprisonment, with hard labour. The facts of the case, as deposed to at the coroner's inquisition and before the police magistrate, have been reported in these columns.* They were to the effect that deceased, who was a barmaid at the Boston Arms, Holloway, went to reside in the house of the male prisoner on Nov. 9th, 1885, and that she died there on Nov. 20th. A few weeks previously she had consulted a medical man on the question of her pregnancy. The friends of Clifford were not communicated with during her fatal illness, nor in fact until she had been dead two days. Turnbull signed a certificate as to the cause of death, alleging that deceased succumbed to "typhoid fever seven days, congestion of the lungs three days." At the post-mortem examination it was evident that pregnancy had advanced to about three months, that an abortion had recently taken place, and that septic metritis and peritonitis had followed as a consequence of the abortion. There were three superficial lacerations in the vagina—one just within the orifice, one at the middle, and a third on the cervical portion of the uterus. Beneath each was some extravasated blood. At the interior fundus of the uterus there was a circular pink patch about an inch in diameter. The organ was in every way enlarged. In the right ovary was an orange-coloured corpus luteum five-eighths of an inch in its smallest diameter. It contained an altered clot in its interior, which broke up into small particles on manipulation and section, for the organ had become softened from post-mortem decomposition. The corpus luteum was quite half the size of the ovary. The medical men who made the inspection found no recent organic disease save that referable to the abortion, and no old organic disease beyond the atrophy or non-development of one kidney, and moderately marked "shaved beard" pigmentation of the intestine—if the latter can be considered as pathological. There was no evidence of typhoid fever; and the congestion of the throat and lungs was such as is usually met with in cases of acute septic poisoning or infection. It will be remembered that, except for an ordinary cold, deceased appeared quite well when she visited her parents, only a few hours previously to her entering Turnbull's house.

The case presents several points of great interest from a medico-legal point of view. That deceased had been pregnant and had recently aborted was not questioned at the trial by the counsel for the defence, who pleaded for an acquittal on the grounds that Turnbull was not cognisant of the facts just mentioned. It is curious to note that, although the indictment charged the prisoners with the crime of wilful murder, and on a minor count with felonious assault, neither the counsel for the prosecution nor for the defence appeared to entertain a middle course between murder and nothing. The question of manslaughter was suggested by the judge, on the ground that the prisoners might be guilty of culpable and criminal negligence, either in not having taken reasonable care to ascertain the exact nature of the illness, or in failing to render such assistance as the case required. It was fortunate for the prisoners that the jury adopted the suggestion and returned a verdict of manslaughter only, for, as Mr. Justice Denman remarked when passing sentence, it was idle to suppose that Turnbull and Nottage were not aware of all that happened from the time deceased went to reside with them until the day of her death. Touching the question of doubtful diagnosis, the medical witness for the prosecution admitted that if extreme care were not taken it might be possible to mistake the peritonitis and the other symptoms from which deceased suffered for typhoid fever, and that the post-mortem evidence was more trustworthy than the symptomatic. This proposition is illustrated by a case of undoubted instrumental abortion investigated at an inquest before Dr. Danford Thomas about two years ago. The abortion had been completed when a medical practitioner of unquestionable repute was called in. For several days he treated the patient for typhoid fever, and on the supposition that she was suffering from that disease sent her into a general hospital, where she died soon after admission. At the necropsy it was discovered that the nates and vulva had been punctured in several places, and the vagina and uterus extensively torn. A professional nurse who attended deceased never suspected that she had aborted. The author of the crime was not discovered. The case was reported fully in our columns. Concerning Clifford's abortion, a juryman asked, "Was it possible for the girl to have procured it herself after she entered Turnbull's house?" The reply was, "Yes, it was just possible, but very improbable." Then as to the lacerations in the vagina, it was admitted by the prosecution that the first might easily have been self-inflicted with the unaided finger, the second possibly so, the third not. According to Taylor, "Any mechanical injury done to the womb always implies interference of some other person in the perpetration of the crime." By this, we presume, is meant injury to the *interior* of the womb, for clearly it is possible for a woman to inflict, with the aid of an instrument, very severe wounds on the vagina and the vaginal portion of the uterus. In his evidence Mr. Pepper admitted that it was impossible to say whether the recent lacerations found in the vagina in the case under consideration were made during an attempt to procure abortion, or to extract the products of conception after an abortion had commenced, or by clumsy instrumentation for cleansing purposes. The inference was essentially a question for the jury, guided as they must be, where the medical evidence is at all equivocal, by collateral testimony; and here it may be parenthetically remarked that a chemise and sheet were discovered in the house on each of which were large blood-stains. As regards the blood and discharge found on the bed and pillows, it was impossible to say that they were not dependent on the advanced state of decomposition of the body—five days after death. It was pure imagination to suppose that they were all due to hæmorrhage from an alleged ulcerated throat, for the stain on the bed was in the middle, and was as large as the outspread hand. It goes without saying that the jury were not satisfied beyond reasonable doubt that an illegal abortion had been procured by someone other than deceased; but looking at the evidence as reported from its medical aspect, it is difficult to convince oneself that such was not the case, especially when read by the light of associated facts. Although it is incumbent on a jury to find according to the evidence, it would be unreasonable to expect them to ignore altogether the consequences of their verdict. Had they decided that a murder had been committed, sentence of death would have been passed on both convicts, for there was nothing to show that Nottage was ignorant of what Turnbull knew of the chief circumstances that transpired whilst Clifford was confined at 146, Hampstead-road; and, as the equitable sentences passed by the judge indicated, there was a wide difference between the guilt of the two persons. On first consideration, the law of criminal abortion seems somewhat Draconic in severity, inasmuch as the illegal act is performed with the full knowledge of its victim, and there is not only no intent to kill, but a strong desire to keep alive. But it must not be forgotten that the woman, especially if she is single, has a powerful motive for assenting to an illicit operation, and that she is generally ignorant of the extreme danger she is running in being a party to its performance. Her judgment is narrowed by ignorance, and perverted by a sense of shame. Very rarely is the accused convicted of the capital offence, and still more rarely is the corresponding sentence carried out. Since the law leaves such wide limits to the jury and such great discretionary powers to the judge, we must expect to meet with convictions and sentences of unequal severity. At the Warwick Summer Assizes in 1885, the prisoner, a medical man named Millerchip, was sent to penal servitude for ten years for *attempting* to procure abortion by means of a Lawson Tait's uterine dilator, exactly the same punishment awarded to Turnbull. In each case the sentence was proportionate to the verdict. Legally and technically we subscribe to them, though morally we might hesitate to do so.

It has prevented the ...these institutions from being recognised. It ...forgetfulness of the fact that the care ...and important than the prevention of ...seemed as if the existence of hospitals was the first consideration, and the existence of the community in which they are placed, and by whom they are maintained, but of secondary importance.

There have been ample indications that the Managers are not satisfied with their position. As long ago as nine years the late Dr. CORTIS, a member of the Asylums Board, pleaded at length in our columns for the reconstruction of the Board of Managers on such a basis that they should be brought into direct relation with the various sanitary authorities. The whole question has been considered in detail by the Managers, and circular letters embodying their views have been addressed to the central and to the various local authorities. Again, as recently as last year, the Managers, in making their arrangements for providing hospital accommodation for cases of cholera, strained a point to seek advice as to the health requirements of the metropolis. Nevertheless, there is no material change in their position, and, as a result, London continues to suffer.

The only complete remedy is to be found in legislation. The provision of hospital accommodation for infectious disease must be a branch of the sanitary administration of the metropolis, if the calamitous occurrences of the last fifteen years are not to be repeated. Parliament has begun its work during the present week, and upon the opportunity for its members to consider the better government of London, in whole or in part, will depend the welfare of numbers of persons. If we were pleading for the lives of animals lower in the scale than man, or if we were protesting against loss of life from some more violent cause than disease, we are convinced that our utterances would not be in vain. There can no longer be excuse for further delay. The investigations of Mr. W. H. POWER have amply confirmed the decision at which a court of law arrived some six years ago, and every year has added, and is still adding, to the list of those who lose their lives from the continued existence of a bad system. This needs to be clearly appreciated, for it is only when the evil it inflicts upon many is fully understood that we can hope it will receive the attention of the legislative body.

OUR columns are open to every fair and honest representation on the subject of Hospitals. Our predominant note about these institutions is one of praise and gratitude. We cannot imagine medical science flourishing without them. Medical education would be infinitely impaired by any change that reduced them to mere workhouse infirmaries. One huge consolation of the poor would disappear—the hope of relief from the highest members of the profession in cases confessedly out of the common beat of practice, and which, occurring in the rich, would command the attendance of consultants and specialists of every kind. By the beneficent provisions of our great hospitals the lot of the poor in their straits of accident or disease is somewhat assimilated to that of the rich. The distinction of the two classes in the matter of physical suffering is so far obliterated by the kindly action of the rich, which not only secures great advantages to the poor, but improves the art to which one day or other the richest man must be indebted. We adhere without abatement to our high opinion of a British hospital supported by voluntary contributions, and to which the working classes are admitted without too much inquisition in their

Digitized by Google

days of need when grave disease presses. But, as we have said, every fair and honest representation about these institutions shall have a place in our columns. Accordingly we are frequently receiving complaints that these institutions are abused, and one correspondent lately has written us a letter in which he speaks confidently of having discovered the real secret of hospital distress, and the only means of cure. He goes at once to the root of the matter, and declares that hospital *abuse* is the chief explanation of hospital impecuniosity. Mr. MCDONAGH avers that there is no adequate discrimination of fitness of applicants; but he goes much further and maintains that the total disregard of supervision is fostered by the medical staffs of hospitals, whose interest it is to attract a better class of patients, who are found out as unfit, and then invited to call the next morning at the physician's or surgeon's private house, and mulcted of a fee of a reduced character. He is particular in his statement, and says that "many patients of his own who have been able to pay him bills of pounds subsequently received free advice at a general hospital." Were such a system as general as Mr. MCDONAGH represents, it would doubtless squander the money of the benevolent, it would operate disadvantageously and unjustly towards medical practitioners, and it would demoralise the unfit recipients. It was not to be supposed that such statements would pass unchallenged, and they have been met with much point and dignity by a "Physician to a General Hospital," in THE LANCET of last week, who vindicates the motives and the work of his class in hospitals; who avers that there is, at least in some hospitals, a most careful supervision of out-patients; and whose conclusions as to the abuse of the out-patient department—in which, by the way, very little of the hospital money is spent—differ very much from Mr. MCDONAGH'S. He finds that very few of the patients presenting themselves for advice were in a position to pay the fees of any medical man, however moderate. This has certainly been found in other hospitals also. It does not necessarily follow, either, that Mr. MCDONAGH'S chance of getting a bill of pounds from a patient is diminished by the fact of the patient in an emergency or in an exceptional case seeking assistance in a general hospital. The details of such cases would have to be stated with much more minuteness to establish Mr. MCDONAGH'S point. He may have got his account paid because the hospital relieved his patient of a certain liability. We publish to-day another letter from Mr. MCDONAGH re-asserting his position, and with some more detail of statement.

What system is not abused? Is the provident system not abused? Can anything be more disrespectful to the profession or more unjust to its members than some of the experiments that are now being made in the name of providence? The Liverpool papers have lately contained an able letter by Dr. RENTOUL of very much the same tone as Mr. MCDONAGH'S, and lauding some provident arrangements which seem to us very far from satisfactory, which cover the most irregular and inadequate remuneration of medical service, and which often make the medical man not only a sort of drudge, but a source of profit—a sort of money-maker—for a Friendly Society. A list of forty-two Provident Medical Societies is given, with a membership of 224,267 and an income from benefit members of £40,152. In other words, no bill of pounds is forthcoming, as in the case of Mr. MCDONAGH'S patient, who gets occasional relief at a hospital, and presumably on other occasions contracts with Mr. MCDONAGH a debt of pounds; but all medical indebtedness of these thriving artisans and their families is discharged in the handsome sum of 3*s.* 6*d.* a year per member! The most varying remuneration is given in different places. Thus, in the Metropolitan Provident Society 25,000 people are attended for £3290, whereas in Northampton only 16,000 people are attended for the larger sum of £3309. The Manchester Medical Association is held up to admiration by Dr. RENTOUL; and its 16,000 members, a similar number to that of Northampton, raise £4006, which looks pretty well. But how much of this sum finds its way into the pockets of the medical men? Only £1865. Is it not an unreasonable thing that the medical men, whose work makes or draws £4000, receive less than the half of it? We really cannot join in Dr. RENTOUL'S admiration at such a result, or think it, without explanation, one to be copied. We think it possible, and we devoutly hope, that many medical men of Manchester, having no connexion with the Association, but having honourable relations with the honest poor, get more recompense from them than this, even if they occasionally, and under stress of disease or diathesis, try what the hospital physicians can do for them. We do not wish it to be considered that our hospital system is perfect; but some developments of the Provident Societies are little more creditable, and they give a false sense of pride and independence to the members. Let us work steadily for the improvement of both systems, without denying that each has its place in an old and complicated civilisation like our own.

ANOTHER outbreak of disease in which milk is alleged to have been the vehicle of infection is reported by Mr. WYNTER BLYTH as having occurred in the metropolis. It appears that a group of scarlet fever cases were reported from the neighbourhood of Dorset-square, Marylebone, and preliminary investigation pointed to the fact that the only connecting link in common to these attacked was the use of milk from the same dairy. It next appeared that a lad at the dairy in question had also had scarlet fever, but from the dates of the several attacks it became evident that he was not the cause of the outbreak, but that he too had been infected by the milk. The milk supplied by this dairy came partly from Hendon and partly from Swindon. With the aid of the medical officers of health of those places, it transpired that, whilst no suspicion attached to the Swindon Farm, the one in Hendon was seriously implicated. The Hendon milk was transmitted from three separate barns or sheds to three separate dairymen in London, and a further stage was reached when it was ascertained that only the milk sent out from one of these sheds was involved in suspicion; but in the mean time other cases of scarlet fever were ascertained to have occurred in families who derived their milk direct from the Hendon farm. At this stage the evidence was so strong against the Hendon milk that the farmer was requested to stop the supply. He complied with the request, and threw away part of that which would otherwise have gone to Marylebone; but, apparently not believing in its harmful influence, he gave the remainder

Digitized by Google

away to certain poor people, and within a few days eight of the families so receiving it were also suffering from scarlet fever, some patients sickening within about forty-eight hours. So far, it cannot be ascertained that any person employed about the farm had suffered from any affection resembling or having affinity with scarlet fever, but it is stated that one of the cows is "suspect." It will be remembered that on several previous occasions scarlet fever has been distributed through the agency of milk, and that cows suffering from some apparently trivial ailments have appeared in some mysterious way to have been directly concerned in the spread of the infection. Mr. POWER, of the Local Government Board, is the inspector who has specially pointed to the possibility of there being some connexion between certain bovine affections and the distribution of scarlet fever to the human subject through the agency of milk, and we are glad to learn that from the first he has been engaged in investigating the circumstances of this outbreak, and that the "suspect" cow has been purchased and sent to the Brown Institution with a view to an exhaustive investigation by Dr. KLEIN.

Until the official report on this interesting outbreak is issued, it would be premature to express any further opinion as to its actual origin and method of diffusion. But one point merits attention. It has for some time past been hoped that proper sanitary control over dairy farms would suffice to prevent milk from such farms becoming a means for the diffusion of disease. But here we have to deal with what is admittedly a "model" farm, having excellent water-supply and means of drainage; and the fact of scarlet fever being diffused by means of the milk sent out from it should go to show that, however valuable and necessary strict sanitary control over dairy farms may be, it can never suffice altogether to prevent the spread by means of milk of obscure diseases, such as diphtheria and scarlet fever. We therefore repeat the advice which we have more than once given, that all milk should be boiled or otherwise cooked before it is used for human consumption. In this respect continental countries are in advance of Great Britain, where alone large quantities of uncooked milk are regularly used as food.

We have to deplore cases that have recently come before the Law Courts, in which our profession has been disgraced by some of its members. There are, and always will be, "black sheep" in every flock. The clerical, the legal, as well as the medical profession have their *mauvais sujets*, and the profession of arms is not wholly spotless, we believe; nevertheless, there is no comfort to be derived from the fact that vice has its representatives everywhere. The medical body ought to be, and we believe is, especially sensitive on the subject of honour and morality. Its members occupy a unique position; they stand in an altogether exceptional relation to the community. They are in a distinctly personal sense the trustees of [illegible] character. They know more of their clients' secrets than any other class of men can possibly know. A man tells the minister of religion whose advice he seeks and the lawyer he instructs just as much or as little as he pleases about his inner life and most private affairs; but before [illegible] he stands unmasked, and no effort of his can conceal the state of his health, the chances of his living or dying, or the manner of his life, from the expert practitioner of medicine. It is so with men and women alike, of all ranks and conditions. The medical adviser is the one "other person" to whom all secrets are discoverable, and from whom practically nothing can be hid. This being so, it seems strange that society does not require heavier bail and stronger guarantees for the good conduct of the men it permits to practise medicine in its midst than are now deemed desirable; above all things, it certainly appears inexplicable that the community, as represented by the State, does not insist that the governing bodies of the profession, the *Colleges*, should actually exercise such control as they claim to have over the practice of their members and licentiates. There are Colleges of Physicians and Colleges of Surgeons, and if only these distinctly *professional* bodies were anything more than mere licensing faculties, they would be powerful agencies of supervision and control. In the old days the College of Physicians of London had the power of reprimanding its Fellows, Members, and Licentiates, and could, if need be, commit to Newgate any person either daring to practise within its jurisdiction without its leave, or so practising as to transgress its bye-laws. With the growth of a liberal spirit and *régime*, which may readily degenerate into licentiousness, the prerogative of control has been restricted until it has become little more than a name. Meanwhile the College of Surgeons, which never distinguished itself by any care for the honour of the profession, has come to be wholly absorbed with squabbles about collegiate policy taking place within its own walls, and is far too busy to think of what is going on without, even though membership at Lincoln's-inn is now, and has for many years past been, the commonest qualification of general practitioners.

We are convinced that the time has arrived when it is urgently necessary that the Colleges should be compelled, if not by the State and community, by the profession itself, to assume the position and discharge the responsible duties of Boards of Control. It is intolerable that the social credit and common repute of the medical body should be progressively reduced by the nefarious proceedings of qualified quacks and unscrupulous professional practitioners. We hear a good deal about the necessity of exposing and repressing the unqualified pretenders whose lawless trade in physic is supposed to clash with the interests of qualified practitioners. It is high time that something was said, and to the purpose, about internal organisation and control. We venture to think greater injury is done to "our interests"—yes, even our more selfish interests—by the degradation of the profession in the esteem of the public, which results from the perpetually recurring scandals arising in connexion with the misdoing of qualified practitioners, than by the most nefarious deeds of outsiders.

ALTHOUGH nothing of a very definite character was decided upon at the Council meeting last week, it is satisfactory to learn from their proceedings that at least some members of the Council feel that matters cannot be allowed to remain as they are. Mr. MACNAMARA'S motion (seconded by Mr. THOMAS SMITH), "that a committee be appointed to ascertain and report to the Council the views

Digitized by Google

of the Fellows as regards the advisability of Members being allowed to vote for the election of Fellows as members of Council," was temporarily postponed until after the report of the Committee on the proposed changes in the conditions on which the Fellowship is at present granted had been received and disposed of. Neither of these motions, however, whether passed in their present or in any altered form, will meet the requirements formulated at the late meetings of the Fellows and Members.

Mr. MACNAMARA'S motion, if passed, can do no sort of harm, but it is insufficient. The Association of Fellows, as the mouthpiece of a considerable and influential section of the Fellows at large, has decided not only that Members shall *vote* for the election of *Fellows* as members of Council, but also that the Council shall *include* a certain proportion of *Members* among its number. Hence it is to be regretted that Mr. MACNAMARA has not included in his motion the latter question also.

As regards Mr. HUTCHINSON'S motion to widen the basis upon which the Fellowship is obtained it is premature to speak, seeing that the subject is still under consideration. But if there is any truth in the whisper we have heard, that it proposes that some fifty Members be elected to the Fellowship without examination every year, we may say at once that the proposal does not meet with our approval. In the first place, we doubt very much whether Members would care to accept the Fellowship on such terms. In the next place, we doubt whether fifty Members really eligible for a diploma so strictly surgical could be found year by year. The chief effect of such an arrangement would be to thin out the ranks of the Members and take away the best and most representative men. It would give these men a higher title without ensuring any wider knowledge of surgery, and would thus defeat the object for which the Fellowship was instituted—"in order more effectually to promote and encourage the study and practice of the said art and science of surgery." The selection of the fifty recipients would be a most invidious task, and would probably lead to much jealousy and disappointment. We are far from thinking that the mode of granting the Fellowship is satisfactory. The great hindrance to its acquisition at present is not the *surgical* but the *anatomical* part of the examination; and although some beneficial changes have been effected within the last year or two, there is much room for improvement even now.

Moreover, both Mr. HUTCHINSON'S and Mr. MACNAMARA'S motions leave the *principle* for which we have so long contended quite untouched—the right of all Members of a large Corporation like the College of Surgeons to a voice in its management. That twenty-four Fellows, members of Council, should absolutely control the affairs of a corporation numbering over 18,000 educated men, is an anomaly which has already existed too long, and which in the interests alike of the profession, of the College, and of society at large must be put an end to. We must once again impress on the College authorities that our arguments for an extended franchise do not rest on the fitness of a few to be made Fellows, but on the principle that a corporation should be governed by those through whom and for whom it exists.

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF LONDON.

A MEETING of Convocation was held on Tuesday last, to consider no less than sixteen different questions, as set forth on the agenda-paper summoning the meeting. The chief part of the sitting was occupied with a discussion on a revised syllabus for the matriculation examination recommended by the Annual Committee to take the place of the one now in force. A comparison between the two occupies six pages of a special report, and as the views of no two graduates agree as to what subjects, much less details, should form part of the examination, and many teachers look upon it as a finishing examination for a schoolboy, instead of a necessary preliminary to a degree, the utter confusion of the discussion can be imagined. after a tedious debate, in which probably some twenty speakers took part, the revised syllabus was recommended for adoption without having undergone any alteration. The Senate should obviously have taken the initiative in such a question as the alteration of its entrance examination, and should have been able to ask the assistance of an authoritative Board of Studies, instead of being dependent on the energy and knowledge of one or two individual graduates, and giving an opportunity to every member of Convocation to air his pet educational crotchet. A motto for the University, a thesis for the Doctorate in Law and in Medicine, and a large alteration in the regulations for the LL.B. degree, were in turn brought forward, and the House was counted out at a little before 9 P.M., having spent four hours in proving its unfitness as a working element in the University, and the folly of giving to it in its present form any increased powers. It may be difficult to find a fitting motto for the University, but one for Convocation immediately suggests itself: "Vox et preterea nihil."

HOME AND HOSPITAL TREATMENT OF INFECTIOUS DISEASES.

NOTWITHSTANDING the noteworthy statistics of small-pox mortality around small-pox hospitals issued by the Medical Department of the Local Government Board, no good reasons have yet been urged for doubting the generally beneficial effect on public health of hospital treatment of infectious diseases. When, however, the effect of such hospital treatment upon the proportions of death and recovery among the patients treated comes under consideration, difference of opinion is often expressed, and the need for satisfactory statistics on this point becomes patent. Dr. Hime, the medical officer of health for Bradford, Yorks, in his report on the health of that borough in 1884, urges, on the basis of certain statistics which he gives, "the folly and cruelty of keeping such cases (scarlet fever) at home, to the danger of the public and with such a great chance of killing the patients." We wish, in the interest of public health, confident as we are of the value of hospital isolation of cases of infectious diseases in large towns, that we could accept Dr. Hime's figures as a satisfactory basis for calculation and deduction. The mean percentage of deaths from scarlet fever among the cases treated in the Bradford Fever Hospital in the three years 1882-3-4 did not exceed 8·6; whereas Dr. Hime gives figures showing that the mean mortality among cases treated at home during the same three years was 14·4 per cent. We regret to find that no satisfactory explanation of these figures accompanies the table. There is no reason to doubt the accuracy of the percentages of mortality in the hospital, although from a statistical point of view the value of the figures would have been increased if the facts upon

The ...weighed eighteen grains and ten grains ...under the microscope showed simple ...So far the case may be regarded ...disease, due to simple atrophy of the ...of which Hadden, Coupland, and Barlow have published examples. But the remarkable feature of this case is that the father died at the age of thirty-seven with the same symptoms, and was found to have a spleen which weighed seven and a half pounds; while a brother, still alive, presents the same series of phenomena. This coincidence suggests that the atrophy of the capsules has been in each case congenital—a view which is supported by the microscopical appearances of the capsules, in which no trace of inflammatory action was observed. The enormous splenic enlargement present in all three cases distinguishes them from ordinary cases of Addison's disease, in which hypertrophy of the spleen, though frequently observed, reaches very moderate dimensions. The fact that there should be this tendency, even in ordinary cases, to enlargement, indicates, in Dr. Saundby's opinion, that these enormous spleens depend upon the long continuance and extreme degree of the capsular affection. It is noteworthy that Dr. Saundby could discover no change in the structure of the semilunar ganglia, and that, with the exception of pigmentary deposits, the organs generally were free from obvious alterations.

EVENING CLASSES FOR THE YOUNG.

WHILE supporting the admirable movement in favour of evening classes of a recreative and instructive character to supplement the earlier educationary efforts of the School Board, the Bishop of London, a few days ago, alluded to the value of these classes as opportunities for the employment of spare time in the case of boys thrown on their own resources for amusement after the hours of daily labour. This is a most important matter. There is an intermediate stage in the life of every individual which is by no means a "dead-point," but, on the contrary, is signalised by the dawn of special energies which need to be subordinated by proper influences. The mind never so greatly needs to be developed and cultivated as when it is in danger of being dominated by that part of the nature—the emotional—which stands in closest relation with the lower animal instincts and sensibilities. To throw a boy-man or girl-woman entirely on individual resources for amusement at such a crisis is to do more than can be easily accomplished at any other juncture or period of life in the downward line of retrograde demoralisation and dissolution. We quite agree that music and drawing should form the cardinal subjects of instruction at these evening classes, because they are especially instructive; but lessons in the rudiments of natural science—chemistry, zoology, botany, and the like—might be added, and the mind trained to self-respect and self-improvement by the legitimate stimulation of that desire for knowledge which is itself regenerative when not over-developed or mischievously perverted. But the movement must be allowed to proceed on simple and natural principles without any "goody-goody" or, still worse, sectarian bias, if it is to succeed.

VERTEBRAL ARTHROPATHY.

THE author of a paper in the *Journal de Médecine de Bordeaux*, No. 24, records the following case as the first one of authentic vertebral arthropathy of tabetic origin. He observes also that it is curious to notice the presence of osseous and articular lesions in the absence of other severe tabetic symptoms. A man aged fifty-six came under observation on May 6th, 1885, for an affection of the right big toe that interfered with progression. He had met with many accidents, some of a severe nature, but it was on account of his great toe alone that he sought assistance at the hospital. One day, fifteen years previously, when about leaving home to go to his work, he was suddenly seized with weakness, which, commencing in the trunk, invaded the lower limbs; this weakness led to a change in his occu-

Digitized by Google

pation—from a cooper he became a tailor. About the same time he began to suffer from pains that shot through his limbs. Within the past five years incoördination of gait had set in, his sight became bad, and the pains increased in frequency and severity. In 1883 it was observed that his stature had decreased to the extent of at least twenty-three centimetres, and he was unable to walk without assistance. On admission to the hospital, under the care of M. Denucé, there was dry gangrene of the big toe, for which resection was performed; this was followed by gangrene of the foot, necessitating amputation of the leg, to which the patient succumbed. The interest of the case turns chiefly upon the condition of the vertebræ and hip-joints. The capsule of the hip-joint was much thickened and irregular; three small bony fragments were adherent to the capsule. The head of the femur had totally disappeared, as well as a large part of the neck; in its place there was a smooth vertical surface, shaped like a punch, on the anterior surface of the femur, and the great trochanter was much flattened. The spinal column was much curved laterally. The osseous skeleton showed in many places rarefaction and in others genuine osteophytes. Depressions and rugosities were very marked on the vertebræ; many of the vertebræ were much flattened, and their upper and lower borders markedly projected.

"MEDICAL EDUCATION IN ENGLAND."

MEDICAL Education in England is the subject of three long and interesting letters by Professor Theordor Puschmann which have recently been published in the *Allgemeine Zeitung*. The writer naturally devotes the greater part of his space to a description of the nature and working of the English system, but he also indulges here and there in comparisons between the English and German systems, which are worthy of attention. He is struck, for instance, by the fact that our hospitals owe their foundation to the beneficence, and are still supported by the contributions, of private individuals; whereas in Germany all such institutions have been founded and are supported by the municipality or the State. Englishmen are so familiar with these creations of individual effort that they do not see anything peculiar in them; the foreigner, however, invariably regards them as the most surprising, and perhaps the most enviable, thing which distinguishes England from the rest of the world. The medical students in this country, too, are noticed as being a stronger and healthier set than they are in Germany. This is attributed to the national addiction to out-door exercises; and Professor Puschmann advises his fellow-countrymen who are studying for the profession to cultivate similar pursuits. The essential differences which he finds between the two systems of medical education are reducible to two. In the first place, the general education of the English student is secured only by the obligation to pass the not very difficult preliminary examination. On the other hand, the German student has to spend nine years at the gymnasium, and to pass that bugbear of German boyhood, the "Abiturienten-Examen." Perhaps the English method does not sufficiently guarantee the possession of a due amount of general culture, but the German system is terribly rigid and inelastic. Prof. Puschmann inclines to a compromise between the two. The other great difference is the stress which the English system lays throughout on practice. It may be said that German students get their training in the universities; English students get theirs in the hospitals. The practical end to which all his labours are directed is kept always before the mind of the English student; the lectures he hears are animated by the constant reference to practice, and are therefore always followed with interest. The German professor, on the contrary, does not condescend to this lower level, and keeps well in the region of theory. That the German system does not adequately recognise that medicine is an art is evidently the opinion of Professor Puschmann; and he regrets that the old Bavarian system under which the young surgeon or physician had to complete his training as assistant to a medical man in large practice or in a hospital before he was allowed to practise on his own account, has given way to the Prussian system, which came in with the establishment of the German Empire. "The English," he concludes, "have accomplished wonderful things in other spheres of labour; perhaps in this sphere also we may find something worth our imitating."

INTRA-PULMONARY ANTISEPSIS.

AMERICAN physicians have employed iodoform dissolved in olive oil and ether as an antiseptic injection in the treatment of pulmonary cavities. M. Lépine has advocated the use of weak solutions of corrosive sublimate. M. Gouguenheim has taken up the subject again by experimenting on the cadaver. He believes that the first and second intercostal spaces in front are suitable sites for penetrating to cavities at the upper part of the lung by means of a Pravaz needle; the axillary line and the angle of the scapula are also available sites. The sternal end of the intercostal spaces ought to be avoided. Clinically, the injections ought to be made slowly, in order to prevent cough and hæmoptysis; the liquid should be at the temperature of the body. The treatment may be carried out for a long period. M. Gouguenheim made almost daily injections for a month, and the necropsy revealed in fatal cases no lesions that could be attributed to the injections. The strength of the solution was either 1 part of the sublimate to 2000, or 1000, or 500. One-half to three milligrammes of sublimate in a syringeful of liquid was the quantity injected at each sitting. After the injection pain was but slight, but cough at times violent; hæmoptysis was exceptional and transitory. Generally speaking, an improvement in the physical signs of auscultation was observed at the site of injection, and expectoration was often diminished. We do not think it has yet been shown that any decided benefit has resulted from such intra-pulmonary injections, and in view of the circumstance that phthisical cases even in their final stages not infrequently manifest marked temporary improvement, not only in symptoms but also in physical signs, we must question whether M. Gouguenheim has shown that this treatment yields "most encouraging" results.

BUILDING ON DISUSED BURIAL-GROUNDS.

A CASE of much interest from its bearing on the disposal of disused burial-grounds has just been decided in the Court of Chancery. A piece of land belonging to the trustees of St. Saviour's Rectory, Southwark, was sold by them last year to a firm of builders. It was then found that by the Disused Burial-grounds Act of 1884 buildings could not be erected on the ground in question, while a complication was introduced by a clause in the said Act, which exempts from its control "any burial-ground which has been sold or disposed of by Act of Parliament." The land in dispute had been received by the trustees from the churchwardens of St. Saviour's, though not by purchase, in 1883, an Act confirming their possession, and providing that the land might be sold for building purposes. Then came the prohibitory Act of 1884. The trustees, relying on their private Bill, sued the purchasing firm to complete their purchase, which, on examination of the later Act, they had refused to do. The Vice-Chancellor, however, ruled that the Transfer Act of 1883 did not refer to a sale or disposition within the meaning of the excepting clause in the Act of 1884, and dismissed the suit with costs. The

Digitized by Google

decision in this case has turned upon a delicate point of law, but its justice is apparent. The legal process by which the exchange was effected for their mutual convenience between two similar bodies associated for a common charitable purpose in the present instance could not in any sense be regarded as equivalent to a sale. Practically, the ground could hardly be said to have changed hands. The building firm on their part, though apprised of the various Acts relating to their purchase, could scarcely be expected to decide the point of law involved when that divided experienced legal opinion and was not clear to the vendors themselves. We have in former articles discussed the question of building on land which has been used for burial. Experience has proved that such a proceeding is dangerous to health, as is also the mere breaking up of such ground without due sanitary precautions. In our opinion, the trustees of St. Saviour's Rectory cannot do better with their present unprofitable possession than hand it over to the Public Gardens Association to form one other place of recreation for the inhabitants of Kingston.

STEALING, KLEPTOMANIA, AND MORBID FORGETFULNESS.

As there is a wide practical difference between stealing with criminal motive and the pilfering resulting from a morbid impulse, so there is a distinction to be drawn between kleptomania, properly so called, and morbid forgetfulness of those which may lead its subject to perform acts apparently felonious. Thus, for example, it is quite conceivable that a morbidly forgetful person may take up articles in a shop and carry them away unpaid for without the least intention of purloining or cheating. Obviously, every individual case of this class must necessarily be judged on its merits, or great wrong may be done by conniving at the perpetration of the grave offence under a particularly thin disguise. Nevertheless, the fact should be recognised that this morbid forgetfulness is a true explanation of many otherwise mysterious phenomena of human action; and it is an affection not confined to the rich and well-to-do classes, but common to the population as a whole; so that the poor kleptomaniac depredator should have the benefit of the doubt, as well as the weak-minded possessor of a comfortable home.

ISOLATION ARRANGEMENTS AT LIVERPOOL.

The Town Council of Liverpool have taken another important step towards the solution of the difficulty as to the isolation of the infectious sick, which has so long been a prominent want in the sanitary administration of the city. Happily in the face of an epidemic of small-pox, provided themselves with an excellent small-pox hospital, they are now proceeding to provide means for the isolation of other infectious diseases; and on the 16th inst. a public inquiry was held at the Town Hall by General Carey and Dr. Thorne Thorne, Inspectors of the Local Government Board, as to a loan of £100,000 which the Corporation require for carrying the project into effect. The scheme, as described by the Town Clerk, by Dr. Hamilton, chairman of the Sanitary Committee, and by the city architect, is to acquire a site in the northern part of Liverpool on which to erect a hospital for 140 beds, and to work this in connexion with the Fever Hospital, which contains eighty beds, and is situated in the northern area. The latter hospital, being vested in trustees, has to be acquired by a special Act of Parliament. In addition to the 140 beds thus provided in each case, it is proposed to purchase one or other of two sites lying at the respective distances of ten and fifteen miles from Liverpool, on which to erect a convalescent hospital, to which the patients could be rapidly drafted either by railway or in ambulances. The proposal met with the usual objections which are raised to all such hospitals; but, in addition to these, it is clear, from the evidence given by Dr. Stopford Taylor, that he does not favour the scheme. He maintains that it is most inadequate, and that, quite apart from small-pox accommodation, Liverpool should possess within its limits at least 500 beds for infectious diseases; and he brought forward statistics showing that the average number of infectious cases which occur annually in the city was some 14,000, a total which could not be dealt with by the proposal of the Corporation. He also advocated an alternative site within the boundaries of the city, where such accommodation as he thought necessary could be secured, and in this he was supported by Dr. Flinn. On the other hand, Dr. Gee and Dr. Carter, representing the Liverpool Medical Society, supported the views and action of the Corporation. The conflict of medical opinion is unfortunate, but we see reason why both views should be entertained. The medical officer of health knows better than anyone else what are the real wants of Liverpool, and we can understand his opposition to a scheme which will only partially meet those wants; whereas, on the other hand, any substantial step towards removing a grave blot on the sanitary administration of the city may well receive the approval of the medical profession. The scheme will now be submitted to the Local Government Board, and their decision on it must be awaited.

THE FEARS OF CHOLERA AT GIBRALTAR.

An alarming telegram has been circulated by a news agency concerning the state of affairs in the immediate neighbourhood of Gibraltar. According to this brief message, the persons who died of cholera at the Spanish lines—that is, within some few hundred yards of the English sentinels—have not been properly buried. An offensive odour is consequently stated to prevail in this district, and great fears are entertained that it may occasion a fresh outbreak of the disease. The district in question, commonly designated as the Lenia so as to distinguish it from the English lines, is practically a suburb of Gibraltar, for nearly all its 13,000 inhabitants are dependent on Gibraltar for their subsistence. During the summer the cholera broke out here. At first its existence was denied by the Spanish authorities, so that the official figures ultimately given do not represent fully the extent of the epidemic. According to these statistics, there were in all 416 cases and 191 deaths. Considering that half the population had fled, and that there were many more cases than those officially recorded, it may be said that the Lenia suffered somewhat severely. The fact that the epidemic did not spread to Gibraltar speaks volumes in praise of the general sanitation of the fortress. Nevertheless, many of the inhabitants of the Rock were greatly alarmed. A formidable outcry was raised in favour of establishing a cordon to cut off all communication with Spain. Petitions were even sent to England complaining of the conduct of the authorities in this respect, and demanding that orders should be given by the Colonial Office to isolate Gibraltar. There appears reason to believe that efforts have been made to exaggerate the dangers that menace Gibraltar from without; and certainly it seems somewhat strange that the nuisance caused by the cemetery should not have been noticed before the coldest month of the year. Nevertheless, a cemetery in the sandy, porous soil of this country, situated near to wells supplying drinking-water, constitutes a serious danger which, however, no amount of cordons can modify. In this case the infection would travel below, and not above, ground. Cremation, and not cordons, would be the most logical remedy. At the neighbouring village of Campo-

Digitized by Google

mento it was noticed that every fresh outbreak of cholera followed upon a downfall of rain. The germs in the soil seem to have been carried by the rains to the wells. If, as is now stated, the interments have not been performed with due precautions, we have, in such neglect, another reason to fear a recrudescence of cholera early next year. To all who know how such matters are managed in Spain these apprehensions will seem but too well founded.

DAMP BEDS.

THE sad death of Mr. Maas, the well-known tenor, calls attention very painfully to the peril of sleeping in a damp bed. As a matter of fact, this peril is of the greatest, and it s almost ever present. The experienced traveller rarely hazards the risk of sleeping between sheets, which are nearly sure to be damp, until they have been aired under his personal supervision at a fire in his bedroom. If this be impracticable, he wraps his rug around him or pulls out the sheets, and sleeps between the blankets—a disagreeable, but often prudent, expedient. The direst mischief may result from the contact of an imperfectly heated body with sheets which retain moisture. The body-heat is not sufficient to raise the temperature of the linen or calico to a safe point, and the result must be disastrous in the extreme, if, as is sure to happen, the skin be cooled by contact with a surface colder than itself and steadily abstracting heat all the night through. There is no excuse for the neglect of proper precaution to ensure dry beds. Servants are never to be trusted in this matter, and the managers of hotels, even of the best description, are singularly careless in respect to it.

GENITAL TUBERCULOSIS.

THE interesting subject of genito-urinary tuberculosis was dealt with by Dr. Simmonds at a meeting of the Medical Society of Hamburg (*Dutsche Med. Woch.*, 1886, No. 1). Of 60 cases of tuberculosis of the male generative organs which he had observed, 35 had been examined after death, and amongst these latter the epididymis was affected in 31 cases, the vesiculæ in 29, the prostate in 26, and the testicle in 16—the vesiculæ and prostate being sometimes the starting-point of the disease. In cases of bilateral tuberculosis of the testicle, it is generally believed that the one organ has been infected by the other through the vas deferens and the prostate, but in 2 out of 5 such cases the intra-pelvic organs were entirely free from the disease, which could have been eradicated by a complete castration. As to genito-urinary tuberculosis, it was stated that the origin of the disease was more frequently in the genital than the urinary tract. Of 14 such cases, the kidneys were involved in only 9, the bladder in 13, the vesiculæ in 13, the prostate in 12, and the epididymis in twelve; and clinical evidence was adduced in support of the view that tuberculosis of the urinary bladder is mostly a sequel—even after some years' interval—of tubercular epididymitis. Returning to the cases of genital tuberculosis, it was stated that in 31 out of 35 the lungs were more or less involved, but whether primarily or secondarily could not be determined. There were three cases of acute miliary tuberculosis apparently due to caseous deposits in the genital organs. The majority of the patients were between the ages of twenty-five and fifty; but the list of 60 included two children aged two and seven years respectively, and 12 cases between the ages of fifty and eighty. The duration of the disease was most variable, in some cases lasting for years, in others only a few months. The clinical features were described, and the differential diagnosis detailed. Instances were given of retention of sexual power even in bilateral disease, and in two cases of unilateral disease healthy children were procreated. No evidence of transmission of the disease to the wife was found, and Dr. Simmonds confirmed the opinion that such transmission did not occur. As to etiology, the histories of 26 cases showed inherited tendency in 13; 11 had suffered from gonorrhœa, 4 of which were associated with epididymitis; and in 4 there was a history of traumatism; and it was concluded that traumatism, gonorrhœal or other inflammation, may evoke genital tuberculosis in one who is already the subject of tuberculosis or is hereditarily disposed to it. The prognosis is unfavourable, but castration may be performed where there is no evidence of involvement of the pelvic organs, and only slight changes in the lungs.

NEW LUNATIC ASYLUM NEAR BARCELONA.

ON the 20th of December, with a most imposing ceremony, was commenced a large lunatic asylum in the neighbourhood of Barcelona. This work is being carried on by the administration of the Hospital of Santa Cruz in that city, and its commencement is largely due to the untiring and enthusiastic labours of the celebrated Catalan alienist, Dr. Pi y Molist. From the description of the proposed building, which was read by the secretary to the administration, we learn that it is to be 545 metres in length, the mean breadth being 240 metres, and it is calculated to accommodate from 600 to 700 inmates. There is to be a central portion containing the church and the administrative offices, also two general divisions, one for each sex, besides four special divisions, two for each sex. The grounds are to be enclosed by a fence, which, while quite secure, will afford the patients the opportunity of seeing the surrounding country, thus obviating the depressing effects of enclosure within high walls. The total cost of the building is calculated at £90,000. The site is said to be all that can be desired, and the Barcelonians gratify themselves by the thought that when their asylum is finished it will bear comparison with the best in the world.

RATIO OF INCREASE OF HEIGHT TO INCREASE OF BULK IN THE CHILD.

SOME remarkable observations have been recently made by the Rev. Malling Hansen, principal of the Danish Institution for the Deaf and Dumb, on the progressive increase in height and weight of children, 130 of whom were under his charge. Of these, seventy-two were boys and fifty-eight girls, and they were weighed in batches of twenty, four times daily: in the morning, before dinner, after dinner, and at bed-time. Each child was measured once a day. The weighings and measurements extended over a period of three years, and the results showed that the increase in the bulk and height of the body does not proceed at a uniform rate throughout the year. Three distinct periods, with some minor variations, were observed. In regard to bulk, the maximum period extends from August until December; the period of equipoise lasts from December until about the middle of April, and then follows the minimum period until August. In regard to height, the maximum period corresponds to the minimum period of increase in bulk. In September and October a child grows only a fifth of what it did in June and July. So it appears that during the autumn and the beginning of winter the child accumulates bulk, but the height is stationary. In the early summer, on the other hand, the bulk remains nearly unchanged, but the vital force and nourishment are expended to the benefit of height. When the body works for bulk there is rest for growth, and *vice versâ*. M. Hansen has observed a similar ratio of increase of bulk to increase of height in trees. In regard to the minor variations observed, it is probable that they are dependent—in part, at least—upon the external temperature, so that when this

Digitized by Google

runs up there is marked increase in weight, whilst a diminution of weight occurs with a fall of temperature. M. Hansen's observations were communicated to the International Medical Conference, held in Copenhagen in 1884, and are undoubtedly of considerable importance. Similar observations have been made both by Dr. Percy Boulton (whose results were given in our columns in 1880) and by Dr. W. H. Miller, surgeon to the West Riding Convict Prison. Dr. Miller experimented on about 4000 prisoners for thirteen years, and obtained results that differ sensibly from those of M. Hansen; for he found that the season of maximum increase in weight in adults is from April to August, and the period of minimum increase in adults from September to March. Dr. Miller found the body became heavier in summer and lighter in winter, and he attributes the loss of weight to the more active excretion of carbonic acid gas in the colder months.

SUPRAPUBIC LITHOTOMY; SUTURE OF THE WOUND.

DR. PILCHER recently showed to the New York Surgical Society a man, twenty-one years of age, from whom he had removed fourteen days previously a vesical calculus weighing 2½ grains by the suprapubic method. He departed from the usual mode of treating the case, inasmuch as after removing the stone he closed the wound in the bladder by seven fine silk sutures passed through the muscular and submucous coats only, and then united the wound in the abdominal wall by a continuous suture in the muscles, and three hare-lip pins with interrupted sutures for the superficial tissues. A catheter was retained in the bladder up to the ninth day. The pins were removed on the tenth day, and the patient returned to his home quite well on the eleventh day. In the discussion that followed the record of this interesting case, the opinion was generally expressed that the case was one eminently suitable for treatment by Bigelow's operation, although Dr. Pilcher's treatment had been very successful. The rapid recovery was no doubt due to the closure of the operation wound and its union by "first intention," instead of by the slower process of granulation. This may probably be safely attempted where the calculus removed is small, as in this case; but where a very large stone is removed and the edges of the wound in the bladder and abdominal wall are more or less bruised, such a step would be fraught with danger from a failure of the "primary adhesion" and extravasation of urine.

THE SANITARY STATE OF MILE-END OLD TOWN.

Owing to the allegations of the Mansion House Council on the dwellings of the People as to the sanitary state and administration of Mile-end Old Town, an inquiry has been held by Mr. Cubitt Nicholls, who was appointed for the purpose by the Home Secretary. On behalf of the promoters of the inquiry, it was contended that dustbins were defective, streets badly paved or unpaved, yard gulleys untrapped or defective, house sinks also untrapped and yet in direct communication with the sewers, and that dilapidations and other conditions were injurious to health. Special descriptions were given of property in Canal-road, St. Dunstan's-street, and Maplin-street; and a large tenemented block known as Norfolk House, and which was described as consisting of "model dwellings," was shown to be greatly overcrowded, to have only watercloset accommodation at the ratio of one for every forty-five persons, and to be so bad in other respects that it could only be improved by extensive alterations. The inspector of nuisances was called, and, in answer to inquiries, he admitted that he was the only officer of his class, and this with a population of nearly 120,000 souls. On behalf of the vestry no witnesses were called, the defence being a general one that the authority had taken such action as they legally could do, and that they had not been neglectful of interfering in the interests of cleanliness and health. The contention of the vestry does not, at first sight, seem to be borne out by the facts elicited, but we reserve further comment until the issue of the report, which Mr. Nicholls stated he should make to the Home Office.

THE PROPHYLAXIS OF HYDROPHOBIA.

IT is satisfactory to note that the authorities are, after all, a great deal more in earnest in this matter than appeared likely when we wrote last week. The Commissioner of Police of the Metropolis, as the local authority for the Metropolitan Police District, under the Dogs Act, 1871, 34 and 35 Vict., cap. 56, has issued the following order, dated Jan. 19th:—

"Whereas, mad dogs and dogs suspected of being mad have been recently found in various parts of the metropolitan police district; now I, the undersigned Edmund Yeamans Walcott Henderson, the Commissioner of Police of the Metropolis, pursuant to the Dogs Act, 1871, and in exercise of the powers vested in me as the local authority under the said Act for the metropolitan police district, do hereby order that no dogs not being under the control of any person shall be henceforth for the period of sixty days suffered to be in or upon any thoroughfare or public place, or any place open to the public, within the metropolitan police District. Notice is hereby given that any dog found at large and not under proper control, by being led or otherwise, will be seized by the police in virtue of the above order, and disposed of in accordance with the law. The 3rd section of the Dogs Act, 1871, provides that 'any person who acts in contravention of any order made in pursuance of this section shall be liable to a penalty not exceeding twenty shillings.'"

Colonel Henderson has also issued the following fresh police orders, dated January 18th:—

"Referring to the police order of November 20th last, which expired yesterday, a fresh order in continuation of the same, for a further period of sixty days, has been approved, to commence from to-day. The police order of December 4th, as to muzzling dogs within the metropolis, is to continue to be stringently enforced until further orders."

Sir Richard Cross has also issued a circular from the Home Office stating that it is highly desirable that all local authorities under the Dogs Act of 1871 should rigorously endeavour to stamp out rabies in dogs by following the directions which Professor Brown, the professional officer of the Agricultural Department, has submitted to the Privy Council. The gist of the proposal of Professor Brown is that all dogs should be put under restraint, as they are in the metropolitan police district. The circular has been forwarded to all the courts of general sessions. We sincerely trust that the various local authorities will now do their duty and not be swayed by unnecessarily sentimental feelings. This time the hydrophobia "scare" seems likely to result in an honest and solid endeavour to stamp out the terrible disease, but this most devoutedly-to-be-wished consummation cannot be reached without united and sustained action.

TESTS FOR ATROPINE.

MORE than a year ago Mr. Gerrard showed that the mydriatic alkaloids were possessed of an exceptional power over mercuric chloride. Schweissinger and Flückiger have confirmed these results. The current number of the *Pharmaceutical Journal* contains an article by the last-named chemist, which proves that atropine and hyoscyamine has an alkaline power like the hydrates of sodium and potassium, and thus differs from probably all other alkaloids. Dr. Schweissinger stated that homatropine

Digitized by Google

was devoid of the power of acting on mercuric chloride. Flückiger, however, has ascertained that it perfectly agrees with atropine, whereas hyoscyamine did not yield a precipitate in the solution of mercuric chloride. As a remarkable result corroborative of Mr. Gerrard's test, Flückiger has discovered that atropine is able to impart a red colouration to phenolphtalein paper. Gerrard showed that atropine was more powerfully alkaline than mercury, and so was able to replace mercury in the chloride. Atropine acts on some colouring matters, such as cyanine, methylorange, and tropœolin in the same way as inorganic alkalies, but it does not blacken calomel (mercurous chloride). Cocaine turns litmus paper blue if moistened with either water or alcohol, but it does not partake of the property of reddening phenolphtalein paper. It precipitates mercuric chloride; but it would be impossible to investigate the composition of the white precipitate, inasmuch as it very soon turns red, as in the case of the mydriatic alkaloids. Mercuric chloride and phenolphtalein are therefore to be considered as very valuable tests for alkaloids.

THE UNIVERSITY OF EDINBURGH.

DURING the past year the total number of matriculated students at the University of Edinburgh has amounted to 3525, being 124 in excess of those enrolled during 1884. Of this total, 1829 were enrolled in the faculty of Medicine, 1104 in the faculty of Arts, 114 in the faculty of Divinity, and 478 in the faculty of Law. Of the students of medicine, 736 (or about 40 per cent.) were from Scotland, 664 (or 36 per cent.) from England, 34 from Ireland, 97 from India, 266 from various British colonies, and 32 from foreign countries. The increasing prosperity of the medical faculty is doubtless to be attributed in part to the recent completion of the admirable new buildings, which are specially fitted up for the use of this faculty, and partly to the rivalry which exists between the professors and the lecturers of the extra-academical schools, whose lectures may be attended during two of the four *anni medici* so as to qualify for graduation. From the Graduation List of 1885 it appears that in the faculty of Medicine fifty-nine candidates obtained the degree of Doctor of Medicine, and 187 the combined degrees of Bachelor of Medicine and Master of Surgery. To a munificent donation of £5000 by Mr. William M'Ewan the University has recently been indebted for the practical completion of the extensive new buildings devoted to medicine. One important want, however, still to be supplied, is that of a hall for graduation ceremonials and other university purposes, for which several subscriptions have been announced.

THE REDWOOD TESTIMONIAL FUND.

AN influential committee has, we are pleased to learn been formed for the purpose of making a public recognition and a permanent record of Dr. Theophilus Redwood's services to pharmacy, and the sciences connected therewith, on the occasion of his retirement from the Professorship of Chemistry and Pharmacy to the Pharmaceutical Society, his appointment as Emeritus Professor, and his attainment (in March next) of the age of eighty years. It is proposed to found a Redwood Scholarship, to be held in connexion with the school of the Pharmaceutical Society, which has been for half a century the scene of Dr. Redwood's labours; and with the surplus, if sufficient, it is the intention of the committee to procure a portrait in oils of the venerable scientist, which will be placed in the house of the Society. One, but by no means the only one, of the claims that Professor Redwood has upon the gratitude and kindly memory of the members of the medical profession is his services in connexion with the British Pharmacopœia. His association with this work began in 1851, when he acted as secretary to the committee which was appointed by the Pharmaceutical Society at the suggestion of the Royal College of Physicians. This committee held its sittings up to 1862, working from the year 1858 in conjunction with the Medical Council. In 1865 Professor Redwood was appointed to edit a new edition, which appeared in 1867, the same office being occupied by him in connexion with the editions which appeared in 1874 and 1885. To recapitulate the full list of the benefits which the Professor has conferred upon the science of medicine, both by actual research and by his pen, is impossible in the space at our command. The columns of this journal, amongst others, have frequently been graced by contributions from his facile pen, and for some years he was one of the most valued contributors to its pages. Personally fully appreciating his labours, we note with special satisfaction that they have not been disregarded nor under-estimated by the most prominent members of the profession he has done so much to advance, for amongst the names of members of the committee who have been appointed to superintend the testimonial fund we notice those of the President of the College of Physicians, the President of the General Medical Council, Sir William Gull, Sir Spencer Wells, Dr. Garrod, and others. We commend the scheme to the attention of our readers, feeling confident that the termination of such a lengthy period of scientific work as that performed by Professor Redwood will not be permitted to occur without a generous acknowledgment.

RUPTURE OF THE LIGAMENTUM PATELLÆ.

DR. SANDS of New York has recorded a case (*New York Med. Jour.*, Dec. 26th) of rupture of the ligamentum patellæ, which came under his care some months after the accident. There was then displacement upwards of the patella for about two inches, and entire loss of extension of the leg. Dr. Sands operated, making a long vertical incision over the patella and its ligament. The ends of the ligament were freshened, and an attempt made to approximate them. This failed until several deep cuts were made in the quadriceps extensor. Two silver-wire sutures were then introduced and cut off short. Drains were placed in the joint, the synovial membrane sutured with catgut, and the superficial wound closed. The wound healed by first intention. The limb was kept stiff for five months, when the splint was discontinued. Two months later the man could go up and down stairs without help, flex the knee to a right angle, and extend it fully and strongly. Dr. Sands finds from statistics of the New York Hospital that this accident is met with only once in twenty-five cases of transverse fracture of the patella. It is caused by indirect violence, and is more common in men than in women. The operation is not recommended for recent cases of this injury.

COLLIERY WOMEN AND GIRLS.

MR. ELLIS LEVER writes to inform us that our remarks on the employment of women and girls in the collieries of Lancashire and other districts have led to some misunderstanding of the subject. The intention in our recent article was to describe the character of the work done rather than the precise point of operations. We must not be taken to mean that women are still employed underground. They do not enter the mine or cut coal, but, with this exception, their work at the pit-mouth in carrying, banking, screening, and loading coal is little, if at all, less irksome than that of the miners proper. It appears to us but right to draw public attention to the manifest injustice of imposing on women and girls a daily toil which, wherever it may be undertaken, can only be described as manly, and for which they are physically and otherwise disqualified.

ENT MEDICAL ASSOCIATION FOR LIVERPOOL.

public meeting in Liverpool it was resolved
ble that a Provident Medical Association be
the benefit of the working classes in Liver-
he Manchester system of checking the abuse
harities be introduced. The latter clause
n understanding between the Association and
s, in virtue of which the latter are to ascertain
f applicants, and refer those who are able and
to the provident dispensaries. Mr. Reginald
oke in favour of the motion, and a document
hands of the chairman signed by 100 medical
ining of the abuse of hospitals, and approving
hment of a well-organised and properly con-
ical Association. We have referred elsewhere to
e charitable and the provident principle and to
acy of payments to medical men in provident
, but the need for them is great everywhere.

PRIMARY UNION OF WOUNDS.

istorical parallel between English and French
hich Professor Roux published just after his visit
in 1814, he noted (p. 116) that one of the most
features in the practice of English surgeons was
lection for the primary union of wounds. So
1881, Professor Verneuil, addressing the surgical
the London International Medical Congress, on
y Union of Wounds (Trans., vol. ii., p. 353), was
less in favour of it than were his English
But this international difference is not likely
if we are to judge from a passage in Professor
uérin's recent work "Du Pansement Ouaté." He
wn without reservation (p. 379) "that every
deavour should be made to secure union by the
ion." It is remarkable that a principle so well
on scientific and practical grounds should only
its way slowly amongst a people from whom
g some of the greatest surgical reformers.

THE HABITUAL DRUNKARDS ACT.

PEDDIE of Edinburgh lately read an important
his subject to the Society for the Study and Cure
y, which will shortly appear in the Transactions
ciety. Dr. Peddie speaks on this subject with
ority as a student of dipsomania and one of the
vocates of wise and efficient legislation. He
nd demonstrates the utter feebleness of the
t, which in Scotland, he says, has actually had
f reducing both the number of homes for the
nd their efficiency. He refutes the absurd plea
l liberty as applied to men who are no longer
themselves, and whose only chance of recovering
om a vice that degrades them and ruins their
in a more effective Act. Such a measure as the
Drunkards Act brings legislation itself into con-

CT OF MERCURY ON THE BLOOD.

RY to the general idea that mercurial treatment
the number of red corpuscles in the blood,
finds that they are more frequently increased
ished, usually undergoing progressive augmenta-
the fourteenth day of treatment, after which a
rease is observed. The hæmoglobin always
ven when the corpuscles diminish; M. Galliard
that the weight of the body increases when
a course of mercurial treatment.

AMERICAN DERMATOLOGICAL ASSOCIATION.

SYSTEMATIC progress in medicine in certain directions can only be accomplished by concerted action, and to fulfil this requirement and enable those similarly interested to cultivate friendships whilst enjoying a few days' holiday, the American Dermatological Association holds an annual meeting at some pleasant spot. Besides the number of excellent papers that have been read from time to time, the standing committees on classification and nomenclature and on statistics have done much real service. At the ninth annual meeting lately held, amongst other papers read, we notice those on Angioma Pigmentosum et Atrophicum, by Dr. White; on Multiple Myomata of the Skin, by Dr. W. A. Hardaway; on a case of Mycosis Fungoïde, by Dr. Tilden; Drs. Hardaway and Heitzman follow up the subject of the Electrolytic Destruction of the Hair Papillæ and of Port-wine Marks; Dr. Hyde discusses the Relations of Lupus to Tuberculosis, and Dr. White the Treatment of Lupus by Parasiticides; Dr. R. W. Taylor relates his valuable experience of Syphilitic Reinfection; and Dr. Duhring, in continuation of his valuable series of communications, seeks to prove the identity of Herpes Gestationis with the Vesicular Variety of Dermatitis Herpetiformis.

THE COLLEGE LECTURES.

AT the Royal College of Physicians this year, the Gulstonian Lectures will be delivered by S. J. Sharkey, M.B., on March 18th, 23rd, and 25th, the subject being "Spasm in Chronic Nerve Disease." The Croonian will follow on March 30th, April 1st and 6th, the lecturer being P. W. Latham, M.D., who will discourse on "Some Points in the Pathology of Rheumatism, Gout, and Diabetes." The concluding series, the Lumleian, will be given on April 8th, 13th, and 15th, by W. H. Stone, M.B., on "Man as an Electric Conductor, Condenser, and Electrolyte." The lectures commence at 5 o'clock on each of the above days.

PATHOLOGICAL SOCIETY.

WE may remind our readers that the meeting of February 2nd has been set apart by the Pathological Society for the exhibition and discussion of specimens of intercranial tumours. The Medical Secretary, Dr. Coupland, will be glad to receive as early as possible the names of intending exhibitors and speakers.

SPHYGMOGRAPHY IN A BALLOON.

ASCENSIONS in balloons are now so frequent that we are in possession of many of the physiological phenomena that attend the sudden alteration of pressure. M. Pozzi has taken some tracings with the sphygmograph at a height of 2150 metres. A rapid rise with brief maintenance and rapid descent, disturbed by well-marked dicrotism, were the chief features of the sphygmogram. The peculiarities are, in relation with the lowering of arterial pressure, due to the sudden rarefaction in passing to the higher strata of the atmosphere. They form the counterpart of the experiments of Viveriot with compressed air.

PURIFICATION OF THE RIVER LEA.

A BILL will be introduced into Parliament this session which provides a remedy for the pollution of the River Lea. It is proposed to construct a sewer from the outfall works of the Tottenham Board to the existing marsh sewer of the Hackney Board, who, with the Metropolitan Board, will be required to receive the effluent of the proposed sewer. It is intended that the work should be done at the cost of the Hackney Board, who should be repaid by the Tottenham

Digitized by Google

Board; and after the completion of the sewer it is proposed to inflict a penalty on this board if any sewage be allowed to escape into the Lea. It may be anticipated that this scheme will meet with some opposition from the Hackney Board, but it is to be hoped that the latter will not be forgetful that London must grow, as has been the case with the City Corporation in the past.

ISOLATION HOSPITAL AT BOURNEMOUTH.

A NEW infectious hospital erected under the advice of Dr. Nunn and the Town Surveyor has just been opened at Bournemouth. It is excellently designed to meet the several wants of the town for which it has been provided, including as it does accommodation of a private nature for visitors and general wards for the poorer classes. The site is a good and a convenient one, and the hospital is to be placed in telephonic communication with the office of the Commissioners. That body may take credit for having secured to their town the great additional attraction that those who seek renewed health there will not be likely to find themselves exposed to infection by reason of the absence of the means of isolation which every town, and above all every health-resort, should possess.

MORTALITY IN THE MEDICAL PROFESSION.

A PAPER on this subject will be read on Tuesday evening next before the Medical and Chirurgical Society by Dr. William Ogle, Superintendent of the Statistical Department of the Registrar-General's Office. The subject is one of peculiar, and we may say vital, interest to the profession at large, and the previous statistical work of the author is a sufficient guarantee that the subject will be handled in a manner to command implicit confidence.

THE HAMPSTEAD HOSPITAL.

THE vestry of Hampstead have decided to memorialise the Local Government Board not to allow the hospital of the Metropolitan Asylums Board, which is situated in their district, to be again used for the reception of cases of small-pox. The arguments used in support of the memorial are based upon the reports of Mr. W. H. Power as to the influence of the Fulham Hospital, and on that of Dr. Gwynn, medical officer of health, as to the influence of the Hampstead Hospital.

THE Mayor of Marseilles, in consequence of the small-pox epidemic in that city which we announced last week, has ordered a new hospital for patients suffering from that disease to be opened at the Pharo, whither 120 convalescents, now at the Hospital of La Conception, will be removed. It is stated that the epidemic originated at Toulon, the sanitary condition of which still remains in a most unsatisfactory state.

THE Corporation of Manchester are about to enter upon the execution of the great water-supply scheme which has occupied so much public attention during the past three or four years, a scheme which is perhaps the largest undertaking of the kind in which any municipal body in this country has hitherto embarked. The length of the conduit will, when completed, be almost 100 miles, the source of the supply being the Lake of Thirlmere in Cumberland. Contracts for above 50,000 tons of pipes, involving an outlay of about £230,000, have already been entered into.

DR. J. HUGHLINGS JACKSON has been recently elected Corresponding Member of the Royal Academy of Medicine of Belgium.

WE regret to have to report yet another victim to diphtheria caught in the execution of his professional duty, in the person of Mr. George Searancke, surgeon, of Ashley-road, Bristol. He was attended by his personal friend, Dr. Simpson, and was seen in consultation by Dr. Barrett-Roué, of Clifton, Mr. W. H. Harsant, and Mr. Greig Smith; but, in spite of every effort made on his behalf, grave symptoms of cardiac failure set in, and he died of asthenia on the sixth day of his illness.

WE have received the first number of the "University College (Liverpool) Magazine," which is to appear quarterly. It makes a good start with several articles of considerable interest and literary merit, including one by a medical contributor—viz., Mr. A. Barron, M.B., upon Micro-organisms Mr. Barron treats his subject in a commendably lucid manner, and his paper is illustrated by a well-executed coloured plate. We wish the new venture all success.

AN International Congress of Hydrology and Climatology is being arranged. It is to commence on October 1st, 1886, and is to be held at Biarritz, under the presidency of Dr. Durand Fardel. The Municipalities of Arcachon, Devax, Bayonne, Cambo, and many other places, have sent representatives to assist in the preliminary arrangements. It is expected that numerous medical and scientific men will take part in the Congress.

ON the 18th inst., Surgeon-General McNab died very suddenly at his residence at Preston, from an affection of the heart. The deceased, who was widely known and respected, was a justice of the peace for the county of Lancaster.

THE four children who were bitten by a rabid dog in Newark, New Jersey, and were sent to Paris to be submitted to inoculation by Prof. Pasteur, are reported to have arrived in New York in good health.

A NEW medical, journal entitled *La Medicina Castellana*, has just been commenced. It is published at Valladolid, and is edited by Dr. Don A. de Redondo, professor in the medical faculty of that city.

A PERSON at Natal is bringing an action for £1000 against a medical man for alleged malicious arrest and incarceration on the ground of insanity. This case is the first of its kind which has occuurrd in the colony.

THE Hygienic Congress, which was intended to be held this year at Vienna, has, we learn, been postponed till 1887.

THE MONT DORE, BOURNEMOUTH.

THERE seems to be no doubt that the three weeks' "cure" at Mont Dore, Auvergne, is beneficial in many cases of chronic catarrh of the respiratory passages, in some of asthma, rheumatic gout, and chronic skin diseases. The mode of action of the Auvergne Mont Dore is not a subject on which entire agreement of opinion exists. Most French physicians, and at all events those who practise at the French station, maintain that in suitable cases the waters are the principal agents in the attainment of the frequent excellent results. Sceptical English physicians are disposed to think that even a three weeks' residence in the mountain air of Auvergne may not be altogether harmful in itself, and may be a very powerful cause in the production of the good results. Which of these two positions is the correct one it

Digitized by Google

is difficult to say. One of the oldest, and certainly one of the most distinguished practitioners at the Auvergne station, Dr. Emile Emond, Chevalier de la Légion d'Honneur, having devoted a large portion of the last twenty years of his life to the Mont Dore, is a strong believer in the efficiency of its mineral waters, and is of opinion that a mere stay of two or three days is inadequate to account for the marvellous improvement which it is certain that he and many others have witnessed.

The Mont Dore, Bournemouth, is an establishment designed as a sanatorium with the object of carrying out as far as possible the treatment pursued at the French station. It is perhaps needless to say that there is a difference between the Bournemouth imitation and its prototype. It could not be otherwise. But the presence of Dr. Emond during the winter months will guarantee that the method of treatment is the same as at Auvergne. The Bournemouth sanatorium is situate almost in the centre of the town on the east side of the long narrow strip of pleasure-grounds, and consequently is in uninterrupted communication with the sea air, enjoys perfect shelter from cold winds, and possesses every climatic advantage that the situation affords. At this inclement season of the year, the contrast between London and Bournemouth is as striking as it is grateful. The Mont Dore has been erected with great care, and every attention appears to have been paid to the sanitary arrangements, lighting, warming, and ventilation—at all events so far as the residential portion of the building is concerned. The baths and hydro-therapeutical apparatus, too, are now almost completed, and in their final construction have had the benefit of the advice and supervision of Dr. Emile Emond. The principal communication between the hotel and the hotel is by means of a landing and flight of stairs covered in by glass sides and roof; arrangements are being made, we understand, for the more efficient warming of this corridor. At the foot of the staircase, on the basement of the building—one faces three doors: the one on the right hand leads to a most luxurious and exceedingly well ventilated Turkish bath, the central one is the ladies' entrance to the Mont Dore system, and the third door is the gentlemen's entrance. The south side of this compartment contains a buffet, at which the Mont Dore waters may be drunk. The male and female sections are exactly alike. There is first a dressing-room similar to what is customary in Turkish baths; the atmosphere of this chamber, and indeed of the whole of the baths, is kept at a uniform temperature of about 75° F. The long corridor leading from the dressing-room is lined on one side by a series of small cubicals, in each of which there is a bath provided with hot and cold water, salt water, and a douche fitted with a rose or a nozzle. Arrangements also exist for galvanic baths. On the opposite side of the corridor is a series of four rooms. In the first there is a vaporarium constructed of wood and shaped like some dustbins, with an aperture in the roof through which the head of the bather, who sits inside, projects; the vaporarium is filled with hot steam—prepared from the Mont Dore waters. In this room there are also powerful douches both of water and steam. The second chamber contains in its centre a kind of cauldron, which when in action emits steam from several spray pipes; this is filled with the imported waters of Mont Dore. At each corner of this apartment a rose projects, and when the system is in action the whole room is speedily filled with vapour. Here the patient inhales the steam and is at the same time enveloped in vapour. In the third apartment is a series of sprays worked by steam, and fed or charged with Mont Dore water by means of an aspirating tube that acts in the same fashion as Lister's spray. The fourth room is fitted with all the necessary apparatus for treating the nose, throat, eyes, and external ears. In addition there is another bath-room in which water is kept at a uniform temperature of 45° C., and also a compartment where gargles may be carried out. The architecture is Moorish complete. The patients drink and use in inhalations the waters imported from Mont Dore. But whenever large quantities of fluid have to be employed, as in baths, ordinary waters prepared by Messrs. Allen and Hanburys so as to be artificially identical with the genuine natural water are used. Dr. Emile Emond believes that the beneficial effects are largely due to the mode of administration of the waters, inhalations, aspirations, and irrigations.

At present there are under treatment cases of chronic bronchitis, phthisis, asthma, eczema, chronic pharyngitis, and clergyman's sore-throat. The treatment has only been imperfectly in operation for three months, and it is difficult to speak at present positively, but Dr. Emond thinks the results that have hitherto been obtained at Bournemouth are most encouraging. It speaks well for the future good management of the place that the directors have thought it advisable to appoint a resident physician to look after the comforts and necessaries of the patients who reside at the Mont Dore; and Dr. E. P. Philpots, who is well known as the proprietor of a successful sanatorium—Bourne Hall, at Bournemouth itself—has recently been appointed manager of the new institution. Under present arrangements Dr. Emile Emond will reside at the Mont Dore every winter. The system of baths and inhalations and the like is under his sole supervision.

SPONTANEOUS BLENNORRHAGIC CONJUNCTIVITIS.

PROFESSOR FOURNIER, the well-known dermatologist of Saint Louis, recently called attention in a clinical lecture to an interesting form of conjunctivitis arising in connexion with gonorrhœa, but which is quite different in its origin from the ordinary purulent conjunctivitis produced by the contact of gonorrhœal pus with the conjunctiva. By the observation of a patient suffering in this way he was able to astonish the beholders by telling him that he was suffering from a urethral discharge, without taking the clothes off the bed or even examining the genital organs; but when this was done, it was found that such was the case, and that the patient had a veritable urethritis, of which, through ignorance or neglect, he was himself unconscious.

The eye becomes affected during gonorrhœa in two ways. There is first the ordinary purulent conjunctivitis, which is invariably produced by the inoculation or transference of purulent matter from the genital organs by direct contact; and there are other affections of the eye which arise during an attack of gonorrhœa, but which are not produced in this way, but rather by some internal cause in the same way as an arthritis or sciatica. This is the true disease of the eye associated with blennorrhagia. The other is an accident, and moreover it is far more common; for every purulent ophthalmia there are fifty of this nature. It is not always of the same type; sometimes it is an aquo-capsulitis, sometimes an iritis, and sometimes a conjunctivitis. In the latter case the eye looks red and vascular, but there is seen on close examination a sort of œdematous infiltration, which when well marked forms a kind of pad round the corneal margin. Unlike most inflammations of the conjunctiva, it produces hardly any subjective symptoms. There is hardly any pain, no photophobia, and only a slight sensation of itching, and, as a rule, patients continue at their work without any inconvenience, and if they do consult a doctor for their urethritis they say nothing about their eyes. This remarkable absence of pain or inconvenience in the eyes permits the patients to make full use of them, and a man looks about him without any shutting of the lids or much watering of the eyes, and it was this fact which brought the Professor to make the diagnosis of blennorrhagia; it is a striking fact, in which the objective phenomena bear no relation to the subjective, and therefore quickly excite the attention of observers.

As regards the course and duration of the disease, it commences insidiously and increases in intensity for several days, till it reaches a certain stage, when it remains inactive, and no further changes take place till resolution commences, which sometimes is effected very quickly. The average duration varies between ten and twenty days. It often presents a curious shifting character, which reminds one of the phenomena of rheumatism: for example, it may begin in one eye, which after a time is cured; then it appears in the other, and perhaps goes back again to the eye first affected. Another interesting fact about it is its obvious connexion with rheumatism of a gonorrheal origin. Not all cases of gonorrheal rheumatism present the disease of the eye, but in many cases of that affection the eye phenomena have a tendency to recur two, three, or more times, as was the case in the patient the subject of the lecture who during the

Digitized by Google

four months of his rheumatism had had numerous attacks in the eyes. As regards the seat of the lesion, it may be very localised, either to the mucous membrane of one lid or to a portion of the ocular conjunctiva.

It may be urged that this is only a very mild form of the well-known purulent conjunctivitis, but a consideration of their evolution and anatomical characters shows that there is in reality no relation between them. The purulent conjunctivitis affects only one eye as a rule, while the form under consideration more often affects the two eyes; the former retains its hold on one eye, while the latter is migratory, and shifts from one to the other. Second attacks of purulent conjunctivitis are rare, because the patient has learnt the dangers of the gonorrhœal pus, but the rheumatic variety will often return with each successive urethritis. Finally, the terminations of the two diseases are totally different,—the one requires most energetic treatment to save the eye, while the other does best when left alone or with mild applications.

As to treatment, the Professor advises the protection of the eye with smoked glasses, which is all that is necessary in mild cases; but when the disease is more pronounced, it may be necessary to keep the patient indoors, to interdict all reading and stimulating drinks, and to give eye douches of tepid water; or, if there is any indication that the iris may become infected, he uses atropine drops.

THE UNIVERSITY OF LONDON.

THE meeting of Convocation on the 19th inst. was a prolonged one; but the House was counted out before all the notices of motion on the agenda paper had been exhausted. Considerable time was spent in considering a report from the Annual Committee recommending changes in the matriculation examination. The amended syllabus drawn up in the report contains alterations in the details of the subject of languages, the omission of modern geography (!), the substitution of mechanics for natural philosophy, and in place of chemistry one of the following branches of experimental science at the option of the candidate—viz., 1, chemistry; 2, heat and light; 3, magnetism and electricity. Some difference of opinion existed as to whether the severity of the examination would be increased or diminished by these changes; and amendments were moved to introduce other optional subjects, such as physiography, drawing, and the science of music, and to diminish the number of obligatory languages. Eventually the motion to adopt the revised syllabus as presented in the report was carried. Another motion to extend the list of questions on the paper, so as to allow the candidate for matriculation a choice, was proposed by Dr. Weymouth, seconded by Mr. Spratling, and carried. A resolution to adopt a motto in connexion with the University arms was proposed by Mr. Bentwitch, seconded by Mr. Cross, and carried, the subject being referred to the Annual Committee. The next question discussed was one affecting the legal and medical faculties. It was a proposal to extend the principle of examination through an "original printed thesis," recently applied to the D.Lit. and D.Sc. Examinations, to the Doctorate of Laws and Medicine. There was considerable opposition to the motion, Mr. Howse and Dr. F. Taylor condemning it, but the debate was chiefly confined to the graduates in laws. The motion was lost. The consideration of changes in the LL.B. Examination was referred to the Annual Committee, and the sitting was suspended.

BRITISH MEDICAL BENEVOLENT FUND.

THE annual general meeting of subscribers to the British Medical Benevolent Fund was held on Thursday, Jan. 14th, at 31, Lower Seymour-street, the house of the Honorary Financial Secretary, Mr. Field, at 4 P.M., when Mr. J. F. France, J.P., Vice-President of the Fund, took the chair in the unavoidable absence of the President, Sir Geo. Burrows. The financial statement was submitted, and the annual report of the committee for the past year was read by the Treasurer, from which it appeared that the donations during 1885 had amounted to £808, and the subscriptions to £1229; a total of £2037: an increase in the amount of donations, while the subscriptions had not fallen off much, inasmuch as the total received showed a slight increase upon that of last year. The disbursements during the year had been, in grants, £1894; in annuities, £1086; in all £2980; and the entire expense of collecting and distributing this large sum (over £5000) had been £141, or about 3 per cent.; including stationery, collector's commission, the printing and postage of the report (a copy being sent to each subscriber), the postage and other expenses of the honorary secretaries for finance and cases, and the postage and expenses connected with the distribution of nearly £3000 in weekly or monthly instalments (a peculiar characteristic of this fund), carried out in an admirable manner by the Cheque Banks. The number of cases relieved was 161; but many of those which came before the committee were exceptionally hard, and the committee felt that, had the means at their disposal been larger, they would have been better able to cope with the painful amount of misery, want, and even actual starvation revealed when the touchstone of personal inquiry came to be applied. This year, 1886, is the jubilee year of the fund, and it is intended to make a special effort to render the year memorable in the annals of the fund by holding at an early date a dinner, at which Sir James Paget has kindly consented to preside, by means of a special appeal to every registered medical man, and by an effort at the meeting of the British Medical Association at Brighton in August, to collect the honorary local secretaries together in a meeting, and try to induce prominent medical men in districts and towns not now represented upon our list to take an interest in the work, accept the post of local secretary, and so aid the committee in the work of helping those who are known to be trying to help themselves, and rescuing those who, but for the help of the fund, would have sunk in the struggle. In the annuity department there were three deaths, and seven fresh annuitants were elected, making a total of fifty-seven. There are, however, still forty-four eligible candidates waiting for a chance of election, all over sixty years of age, not one enjoying an income of £10, and most of them past work and practically penniless, and the committee would most strongly urge their claims upon the profession. Mr. S. H. Byam joined the committee in the place of Mr. Thomas Smith (resigned); and Dr. Habershon was elected a vice-president in the room of Mr. W. B. Page, whose death the fund has good reason to deplore.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6133 births and 4149 deaths were registered during the week ending January 16th. The annual death-rate in these towns, which had been equal to 25·5 and 22·5 per 1000 in the preceding two weeks, rose again last week to 23·8. During the thirteen weeks of last quarter the death-rate in these towns averaged only 20·0 per 1000, and was 2·6 below the mean rate in the corresponding periods of the nine years 1876-84. The lowest rates in these towns last week were 17·2 in Hull and Sunderland, 18·6 in Sheffield, and 19·1 in Birkenhead. The rates in the other towns ranged upwards to 30·6 in Manchester, 31·3 in Plymouth, 31·8 in Portsmouth, and 32·7 in Halifax. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 495 and 448 in the previous two weeks, declined last week to 435; they included 156 from whooping-cough, 111 from measles, 46 from scarlet fever, 41 from "fever" (principally enteric), 39 from diphtheria, 37 from diarrhœa, and 5 from small-pox. No death from any of these zymotic diseases was recorded last week in Derby, whereas they caused the highest death-rates in Oldham, Nottingham, and Plymouth. The greatest mortality from whooping-cough occurred in London, Portsmouth, and Brighton; from measles in Nottingham and Plymouth; from scarlet fever in Norwich, Leicester, and Birkenhead; and from "fever" in Norwich. The 39 deaths from diphtheria included 22 in London, 5 in Liverpool, 3 in Bristol, 2 in Portsmouth, and 2 in Leeds. Small-pox caused 6 deaths among the residents of London and its outer ring, 2 in Liverpool, 1 in Manchester, and 1 in Cardiff. The number of small-pox patients in the metropolitan asylum hos-

Digitized by Google

pitals situated in and around London, which had declined in the preceding nine weeks from 90 to 35, were again 35 on Saturday last; 11 patients were admitted to these hospitals last week, against but 2 and 1 in the preceding two weeks. The Highgate Small-pox Hospital contained 5 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 384, 610, and 518 in the preceding three weeks, were 534 last week, and exceeded the corrected weekly average by 45. The causes of 90, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Portsmouth, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Oldham, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·6 and 22·9 per 1000 in the preceding two weeks, further rose to 23·9 in the week ending Jan. 16th, and was 0·1 above the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 18·1 and 19·7 in Greenock and Perth, to 26·0 in Paisley and 26·5 in Glasgow. The 589 deaths in the eight towns showed a further increase of 24 upon the numbers in the previous two weeks, and included 13 which were referred to diarrhœa, 9 to whooping-cough, 8 to diphtheria, 6 to "fever" (typhus, enteric, or simple), 5 to scarlet fever, 2 to measles, and 2 to small-pox; in all, 40 deaths resulted from these principal zymotic diseases, against 32 and 45 in the preceding two weeks. These 40 deaths were equal to an annual rate of 1·8 per 1000, which was 0·7 below the mean rate from the same diseases in the twenty-eight English towns. The 12 deaths attributed to diarrhœa exceeded the numbers in recent weeks, but were slightly below the number in the corresponding week of last year. The fatal cases of whooping-cough, which had increased from 7 to 15 in the preceding four weeks, declined again to 9 last week, and included 7 in Glasgow. The 8 deaths from diphtheria showed an increase upon recent weekly numbers, and also included 7 in Glasgow. The deaths referred to "fever," which had been 2, 8, and 5, in the previous three weeks, were 6 last week, of which 3 occurred in Glasgow. Four of the 5 fatal cases of scarlet fever were also returned in Glasgow. Both the deaths classed as small-pox were attributed to chicken-pox. One occurred in Glasgow and 1 in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding five weeks, from 178 to 132, rose again last week to 145, but were 54 below the number returned in the corresponding week of last year. The causes of 82, or nearly 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 27·7 and 28·8 per 1000 in the preceding two weeks, rose again to 33·3 in the week ending January 16th. During the thirteen weeks of last quarter the death-rate in the city averaged 27·0 per 1000; the mean rate during the same period did not exceed 19·5 in London and 19·0 in Edinburgh. The 350 deaths in Dublin last week showed an increase of 39 upon the number returned in the previous week, and included 30 which were referred to the principal zymotic diseases, against 32 and 15 in the preceding two weeks; 19 resulted from whooping-cough, 4 from scarlet fever, 4 from "fever" (typhus, enteric, or simple), 3 from diarrhœa, and not one either from small-pox, measles, or diphtheria. These 30 deaths were equal to an annual rate of 4·4 per 1000, the rate from the same diseases last week being 2·7 in London and 0·6 in Edinburgh. The fatal cases of whooping-cough, which had been 10, 17, and 8 in the previous three weeks, rose last week to 19, and exceeded the number in any week of last year. The deaths referred to scarlet fever and diphtheria also showed an increase upon the numbers in the previous week. Eight inquest cases and 11 deaths from violence were registered; and 74, or nearly a third, of the deaths were recorded in public institutions. The deaths of infants showed an increase, whereas those of elderly persons corresponded with the number in the previous week. The causes of 22, or nearly 10 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

ADMIRALTY. — The following appointments have been made: Staff Surgeon H. J. Madders, M.D., to the *Hyacinth*; Staff Surgeon Michael Fitzgerald, to the *Caroline*; Surgeon Nicholas C. Ross, to the *Penguin*; Surgeon Thomas Nunan, M.D., to the *Cambridge*.

ROYAL NAVAL ARTILLERY VOLUNTEERS. — London Brigade: John Arkle Waring to be Surgeon.

ARTILLERY VOLUNTEERS. — 1st Inverness-shire: James Milne Chapman, Gent., M.B., to be Acting Surgeon.

RIFLE VOLUNTEERS. — 16th Middlesex (London Irish): Surgeon Arthur Cæsar resigns his commission.

Correspondence.

"Audi alteram partem."

MR. HORSLEY'S CRITICISM ON PROF. SCHIFF.

To the Editor of THE LANCET.

SIR,—A student was once asked, "What would be the result of tying the carotid artery"? He replied, "The pneumogastric nerve is in such close relation with the carotid artery that in tying the artery the operator would inevitably tie the nerve with it, and the result would be death." The Brown Professor's criticism on Professor Schiff's experiments on the posterior columns of the cord is of like nature: "Schiff has taught that the posterior columns of the spinal cord are conductors of tactile sensation direct to the excitable area of the cortex; but Mr. Horsley shows that the results obtained by Schiff are to be explained by the injury that is unavoidably done to the motor tracts in the spinal cord." (THE LANCET, Jan. 2nd.)

In the case of the ligature of the carotid artery above mentioned, if the student whose answer is recorded were himself the operator, his prediction would in all probability be verified to the letter in spite of the lack of natural sequence between ligature of the carotid artery, ligature of the pneumogastric, and death. The section of the posterior columns without injuring the neighbouring portions of the cord unquestionably requires higher skill than is necessary to avoid including the pneumogastric in ligature of the carotid; and it is not improbable that many an operator may have found that he has cut structures he did not mean to touch. From the lack of success of one operator, however, the lack of success of other operators cannot safely be inferred. Those who have witnessed Professor Schiff operate, and have afterwards seen at the post-mortem and microscopical examinations the wonderful accuracy with which the parts cut or removed corresponded with the intention of the operator, will be slow to charge him with the source of fallacy put upon him by the Brown Professor.

I am, Sir, your obedient servant,

WILLIAM R. HUGGARD.

École de Médecine, Genéve, Jan. 12th, 1886.

GASTROTOMY NOT GASTROSTOMY.

To the Editor of THE LANCET.

SIR,—Mr. Knowsley Thornton, in recording a case in which he removed a mass of hair from the stomach through an incision into the viscus, has applied the term "gastrostomy" to the operation. This use of the term is liable to produce considerable confusion, and to lead to errors in the subsequent tabulation of cases. The word gastrostomy is derived from two Greek words, γαστηρ and στομα; and it signifies an operation by which a "mouth" is made into the stomach, or a permanent gastric fistula is established. It is the operation that has been largely practised for œsophageal obstruction. Gastrotomy, on the other hand, is

Digitized by Google

derived from γαστηρ and τομη, and denotes an incision made into the stomach. The conditions demanding, and the mode of performing, these operations are quite distinct. It is therefore very important that they should be kept quite distinct, and no confusion between them allowed to creep into medical literature by a wrong use of the terms applied to them.

In Mr. Thornton's paper, and also in his letter, he referred to Schönborn's case of gastrotomy for a ball of hair in the stomach, which, like his own, was successful. He might, however, have considerably enlarged his list of gastrotomies for the removal of foreign bodies from the stomach. For it matters not whether the offending substance be a knife, a fork, a spoon, a bar of lead, or a ball of hair—the essential reason for the operation, its mode of performance, and its dangers, are the same; and Mr. Thornton's argument is materially strengthened by the great success that has attended this operation, whatever the cause for which it has been undertaken. In the "Medical and Surgical History of the War of the Rebellion," Dr. Otis gives full references to many of the cases, but the most complete list of cases is furnished by Dr. Ashhurst in a note to Mr. Henry Morris's article on Injuries and Diseases of the Abdomen in the fifth volume of the "International Encyclopœdia of Surgery." In this table are placed thirteen undoubted cases of gastrotomy for the removal of foreign bodies from the stomach, and ten of the patients recovered, while an eleventh case ended fatally, owing to an indiscretion in diet on the part of the patient. There are five other cases which are more or less doubtful in their character, but in regard to two of them the evidence in their favour is certainly very strong; all these cases are said to have terminated in recovery. This operation is by no means a modern triumph. The earliest recorded case occurred about 1602, and the second in 1635, both of them being successful. The foreign bodies removed have most often been knives, forks, and spoons, but the nature of the body to be removed in no way influences the steps of the operation.

I am, Sir, yours faithfully,

January, 1886. CHIRURGUS.

"VISITORS TO SMALL-POX HOSPITALS."

To the Editor of THE LANCET.

SIR,—The attainment of the ideally commendable is evidently easier and more rapid in the bracing atmosphere of the north than under the more relaxing conditions of southern latitudes. We lesser lights, *en bas*, are not clothed with the autocratic power expressed in Dr. Russell's phrase "without saying anything to anybody." We are governed by committees who require a great deal of persuasion to effect administrative reforms. As regards vaccination of visitors to the Western Hospital, the sending of a circular to intending visitors of patients, advising them to get revaccinated before entering the hospital, was for many years considered sufficient and to cover all responsibility, and this in spite of my oft-repeated recommendation of the surer method; and it was only the occurrence of attacks amongst unprotected visitors in 1884 that afforded me a powerful text for the suggestion that their revaccination should be seen to at the Hospital. It will interest Dr. Russell and your readers to know that after the presentation of my report the Committee of the Western Hospital authorised my colleague (Mr. Gale), during my absence, to offer to revaccinate all visitors to dangerously ill patients. This has been freely carried out, and no attacks amongst visitors have since come under notice.

I am, Sir, yours truly,

London, Jan. 18th, 1886. R. D. R. SWEETING.

THE TREATMENT OF PERTUSSIS.

To the Editor of THE LANCET.

SIR,—Perhaps it would interest Messrs. Cory and Harries, whose communications appeared in your last issues, as well as some of your readers, to know that I have seen during the greater part of last year, under the care of the distinguished Professor Monti, at the Vienna Poliklinik, many cases of whooping-cough treated by the use of antiseptics. The results show that antiseptics, if they have not a decided specific action, have at least a powerful influence in limiting the duration of the attack and soothing the sufferings of the little patients.

Professor Monti's system of treatment was as follows:—Inhalations—through a modified Seigler's vaporising apparatus—of carbolic acid (1 per cent. solution) or benzoate of sodium (5 per cent.) four times during the day. Internally, he administered one or other of the following powders in milk every two hours, the dosage being proportioned to the age of the child—viz., muriate or tannate of quinia, benzoate of soda, and white sugar. He found the tannate the most agreeable salt of quinia to administer to children. The duration of the cases treated as above averaged twenty-one days; no doubt some extended longer, but they could always be accounted for by the development of complications. I may also add that in no case treated with carbolic acid were symptoms of poisoning found.

I am, Sir, yours truly,

Dublin, Jan. 19th, 1886. ALFRED J. SMITH, M.B., M.Ch.

ELECTRIC ILLUMINATION IN OPERATIONS UPON THE PALATE.

To the Editor of THE LANCET.

SIR,—On Thursday last, having promised to perform an operation for the closure of a cleft palate, I found myself embarrassed by a failing light. Unwilling to postpone the operation, I gladly availed myself of the suggestion of Mr. Weiss, who was present, to use the electric lamp which he had been demonstrating to the students. Accordingly, having removed the mirror from one of Semon and Vesey's apparatus for illuminating the larynx, and which is supplied by four Leclanché cells, Mr. Weiss held the lamp just inside the mouth, and, by the beautiful, steady, and distinct light thus afforded, I was able to see clearly, better than even by the brightest daylight, and the operation was quickly and satisfactorily concluded. To those who, like myself, have had to postpone such operations, to the distress of the patient and at personal inconvenience, I feel sure that this new adjuvant will prove the greatest boon. The smallness of the apparatus makes it free from any inconvenience, and the almost entire absence of heat renders it void of danger, while the clear brightness of a steady light renders every step in this delicate operation more facile even to practised hands.

I am, yours faithfully,

Grosvenor-street, Jan. 1886. JOHN H. MORGAN.

I'S AND Y'S.

To the Editor of THE LANCET.

SIR,—Mr. Tweedy has very properly and learnedly called attention to the etymology and right spelling of the word "hypopyon," which in a recent issue of THE LANCET is spelt with an *i*, "hypopion." May I point out how frequently and how erroneously the word "phimosis" is spelt with a *y*? In an important surgical work which has been published within the last few weeks, the word "phymosis" occurs over and over again. Now "phimosis," the proper spelling, is derived from the very appropriate word φιμός, a muzzle—is, in fact, the very word φίμωσις; "phymosis" could only come from some such word as φῦμα, a growth, or from θύμος, fumus, smoke, when it should be spelt "thymosis," and would be without meaning. It is incumbent on a learned profession to be careful of its *i*'s and *y*'s, as well as of its *p*'s and *q*'s.

I am, Sir, yours faithfully,

Jan. 13th, 1886. Y. P. Q.

EDINBURGH.

(From our own Correspondent.)

EDINBURGH ROYAL INFIRMARY.

THE Annual Meeting of the contributors to the Royal Infirmary was held on Monday last. The report of a committee appointed to represent the contributors in reviewing the management of the institution during the last twelve months was read and adopted by the meeting. The report spoke highly of the general management during the last

Digitized by Google

twelve months, and detailed some interesting particulars of the work accomplished during that period. 25,000 out-patients and nearly 8000 in-patients had received the benefits of the institution during the year, the former number corresponding to the number of out-patients in the previous year, the latter showing an increase of over 200 in-patient cases as compared with the same period. The total expenditure for the year was £33,474. With regard to subscriptions, it was announced that there had been a slight falling off in the amount of the Hospital Sunday Fund; but some handsome donations had been received, one of the most recent being a sum of £5000 from Mr. R. Mackay Smith. A scheme was suggested by which domestic servants might contribute small sums towards the maintenance of the Institution. During the past year the hospital accommodation has been extended to its full extent. This represents 600 beds, and exhausts all the space which the present buildings place at the managers' command. Two wards must of necessity be kept empty to allow of the transference, whether of medical or surgical patients, to a temporary resting-place when any of the wards have to undergo temporary repair or cleansing, and most of the wards are thus temporarily vacated annually or at least biennially—a system which contributes greatly to the brightness and freshness, as well as to the wholesomeness, of the hospital buildings.

LECTURES ON CLIMATOLOGY.

Dr. W. Felkin, F.R.S.E., commenced this week a series of lectures at the Minto House School of Medicine on the Diseases of the Tropics and Climatology. The course is specially intended for the benefit of students whose duties as medical men are likely to lead them to tropical climes. Dr. Felkin has had unusual opportunities of studying disease in these regions, as he has travelled widely in Africa and the far East, and has combined the practice of medicine and surgery with the extensive geographical and ethnological investigations which have won him recognition in the scientific world. In his introductory lecture delivered last Monday he treated specially the subjects of acclimatization and malaria. The latter he described as the typical disease, a thorough grasp of which was the key to understanding a great number of the special diseases by which tropical life is rendered so dangerous to Europeans and to natives alike. In a school where so many colonial students congregate, and whence so many practitioners are supplied to the colonies, a course of lectures such as this is an inestimable boon; and in Dr. Felkin the Edinburgh School has secured the services of a thorough expert, who, in addition to his large personal experience of his subject, evinces considerable aptitude as a lecturer and demonstrator.

THE ROYAL SOCIETY OF EDINBURGH.

At the meeting of this Society held last Monday, an obituary notice of the late Professor Archer, Director of the Edinburgh Museum of Science and Art, was read by Dr. J. Marwick. The deceased gentleman was widely known in artistic circles as a most successful collector of objects illustrating science and the arts; and his energy may be said to have created the present prosperous and popular museum with which this city is provided. He acted as commissioner of the British Government at several international exhibitions, and at some he occupied the post of one of the judges. Dr. Marwick paid the highest tribute to his personal and social qualities, which were such as to command for him everywhere the highest esteem. Several papers followed, chiefly upon technical subjects. There was a large attendance of Fellows, and amongst the visitors present was the Right Hon. Mr. Childers, who is at present conducting an election campaign in Edinburgh, and who was introduced to the Society's hall by Dr. Russell, F.R.S.E., the chairman of his committee.

MR. BROWNING AND THE EDINBURGH STUDENTS.

Mr. Robert Browning has accepted the Presidency of the Associated Societies of the University of Edinburgh. In answering the requisition sent him, Mr. Browning said that he could only give one response to those who had so enthusiastically greeted his appearance at the recent Tercentenary festival. That reception had created a relationship between himself and them, which he would be highly gratified to terminate by accepting the proffered post of honour.

GLASGOW.

(From our own Correspondent)

THE FACULTY LIBRARY.

For a good many years those using the splendid library of the Faculty of Physicians and Surgeons have felt the want of a full and recent catalogue of the works contained in the library, though the encyclopædic knowledge of medical literature possessed by Mr. Duncan, the librarian, caused this want to be less pressingly felt than it otherwise would have been. Two or three years ago the work of preparing such a catalogue, including lists under the headings of authors' names and subjects, was begun; this work has been steadily carried on, chiefly by Mr. Duncan, and is now completed, the catalogue being ready for issue in the form of a large quarto volume.

GLASGOW HOSPITALS.

Glasgow has had one more added to its hospitals in the shape of a modest undertaking started under the name of "The Glasgow Samaritan Hospital for Women." This hospital, containing three beds and provision for dispensary work, was opened on January 4th. In his opening speech Mr. J. Stuart Nairne, who is surgeon to the hospital, and to whose efforts its establishment is due, claimed that this institution is the only one of its kind in Scotland. He defended vigorously the specialisation of abdominal surgery (the treatment of ovarian and uterine disease) to which this hospital is to be devoted; and mentioned, among other matters, that the rule which prevails in the London Samaritan Hospital would be adopted here—namely, "the exclusion of every person who was ever in attendance on an infectious case"; an excellent rule, which it is to be hoped will be strictly enforced in every instance. The hospital is opened free of debt, but now appeals to the public for support.

LOCK HOSPITAL.

From the annul report of this hospital we learn that the number of patients under treatment during the past year was 357; the average stay of each patient was 32 nights, and the average cost per patient £1 19*s.* 11½*d.* There had been a large proportion of young girls admitted. For the first time in hospital there were 224; for the second time, 80; third, 25; fourth, 19; fifth, 5; sixth, 3; and only 1 for the seventh time. In the autumn of last year a lady who was under a course of medical study in Glasgow, prior to her going as a medical missionary to Japan, took advantage of the opportunities freely afforded at the Lock Hospital of studying disease, and of witnessing the mode of treatment in young women, and in children as well, at the usual visiting hour, along with the surgeon who was on duty. It is expected that the valuable knowledge and experience then obtained will be of great advantage to the medical missionary in her work.

VITAL STATISTICS.

From Dr. Russell's report for 1885 we learn that during last year there occurred in Glasgow 13,486 deaths as compared with 13,929 in 1884. According to the Registrar-General's estimate of the population, this represents an annual death-rate of 26 in place of 27 per 1000 living. Dr. Russell also reports that the fortnight ending Jan. 2nd, 1886, was exceptionally healthy, the death-rate being 24 per 1000, as against 27·2 per 1000 in the preceding fortnight. This was due to the mildness of the weather and the absence of any prevailing epidemic disease among children. Only one case of small-pox was registered, as compared with four in the preceding fortnight.

IRELAND.

(From our own Correspondent.)

DUBLIN HOSPITAL SUNDAY FUND.

By returns recently published I learn that the contributions towards the Dublin hospitals collected on Hospital Sunday in November last amounted to £3976 10*s.* 11*d.*, and, with special donations not included in the above (£491 14*s.* 9*d.*), make a total of £4468 5*s.* 8*d.* This sum included £58 8*s.* 7*d.*, the proceeds of a football match played by the Leinster Branch of the Irish Rugby Football Union,

Digitized by Google

on Nov. 7th, 1885. As compared with the year preceding, these returns show an increase of £69 4*s.* 9*d.*, which, considering the greatly depressed condition of the country, must be regarded as highly satisfactory.

THE SANITARY CONDITION OF DUBLIN.

Mr. E. Dwyer Gray, M.P., formerly chairman of the Public Health Committee of the Corporation of Dublin, in a recent communication with Sir Charles Cameron, medical officer of health, states that, notwithstanding all the recent improvements made by the Corporation, the sanitary state of Dublin is still most unsatisfactory. He refers to the probability of cholera reaching our shores this summer, and regards the ashpit system, more especially in relation to tenement houses, as a source of extreme danger both to the inhabitants themselves and to the neighbourhood. Mr. Gray believes that there is only one effective way of dealing with such cases—viz., by the daily removal by the public authority of all the house refuse from such dwellings. He asks Sir Charles Cameron whether this is not the only really effective way of keeping the yards of the houses in the poorer parts of the city in a proper sanitary condition, and so guarding as far as it may be possible, against those insanitary conditions which promote the spread of epidemics such as cholera. Mr. Gray would go further, and make the rule universal that ashpits should be abolished and house refuse daily removed in every part of the city. Sir Charles Cameron, in his reply, agrees with Mr. Gray's statements, and says that he knows of no measure of greater efficacy against the spread of contagious diseases than the prompt and complete removal of filth from dwellings. The storage of effete and unclean matter close to human dwellings he regards as a relic of barbarous ages, and he believes that it was the most potent cause of the terrible mortality of mediæval cities. Should the Corporation see their way to carry out Mr. Gray's proposal for the total abolition of filth receptacles, he thinks that, with such an improvement and with the pure water-supply the city possesses, it would be well prepared to cope with Asiatic cholera should it invade us.

BELFAST MAIN-DRAINAGE BILL.

The Bill for the purification of the River Lagan, and for the construction of works in connexion therewith, to be undertaken by the Corporation of Belfast, came as an unopposed measure last Monday before one of the examiners of the House of Commons. The regulations contained in the Standing Orders were found to have been complied with.

SUICIDE BY A LUNATIC.

On the 15th inst. a lady named Dawson, aged sixty, an inmate of the Richmond Lunatic Asylum, set fire to her clothes and died from the burns she received. Early on Friday morning the deceased set fire to her night-dress by means of a gas jet over the fireplace during the absence of the night nurse, and died the following day. At the inquest held, evidence was given that the gas bracket was seven feet and a half from the ground, and the jury exonerated the officials of the asylum from all blame in respect to the occurrence, Dr. Lalor, the medical superintendent, promising to lay before the governors, at the suggestion of some of the jurors, the necessity of having the gas jets guarded in some fashion.

Dublin, Jan. 19th, 1886.

PARIS.

(From our own Correspondent.)

THE RECENT CASE OF POISONING BY COLCHICINE.

AT the meeting of the Société de Médecine Légale of the 11th inst. a discussion took place on the case of poisoning by colchicine which was reported in THE LANCET some months ago. Professor Brouardel read a note, giving the results of his researches with a view of elucidating the difficult points of the subject. In referring to the chemical part of his work, the author declared that a search for metals in the different viscera and organs of the woman supposed to have been poisoned by colchicine gave no result. The search for alkaloids, of which the reactions are known were equally fruitless. An extract, however, obtained by maceration and division of the kidneys of the woman, to which some nitric acid was added, produced a violet tint, which by the addition of some potash became an orange red. Professor Brouardel remarked that in the present state of our knowledge this double reaction may be legitimately considered characteristic of colchicine, as all the samples of this substance, treated with nitric acid and potash, always produce the same reaction; the urine of a dog to which a certain quantity of colchicine had been administered produced the same tint by the same reagents. Moreover, this reaction has not as yet been produced in any other substance than colchicine. In referring to the physiological parts of his report, M. Brouardel declared that fragments of the viscera of the supposed victim which were injected into the veins of animals, produced no phenomena characteristic of poisoning by colchicine. In conclusion, the author observed that in a case of poisoning there must be perfect concordance between the points of information furnished: (1) By chemical examination, (2) by the necropsy, (3) by chemical analysis, (4) by physiological experiments. In the case under consideration, the hypothesis of poisoning by colchicine was justified by the symptoms observed during life. As regards the autopsy which was performed more than a year after death, no lesion was discovered which would permit one to attribute death to a natural cause. Moreover, the body was in a perfect state of preservation; but it was ascertained that the soil of the cemetery in which the body was interred had the property of preserving corpses for a considerable time. In performing some experiments in view of ascertaining the toxic character of colchicine, Professor Brouardel obtained the following results: Administered in from four to five centigrammes colchicine is dangerous, and ten centigrammes are sufficient to cause the death of a man.

M. PASTEUR ON RABIES.

A young man who was bitten two days ago by a dog immediately took it to the Veterinary School at Alfort to have it examined, but as the animal did not appear to be affected with rabies it was returned to the owner—a proceeding, in my opinion, rather strange, for certainly the animal should have been kept under observation at least for some days. The young man, however, being naturally anxious about himself, wrote to M. Pasteur asking him to appoint an hour to receive him. The illustrious *savant* immediately replied by letter, and, as it is rather instructive, I give it here in its entirety:—"It is useless for you to come. Every mad dog, whether it eats or not, dies from rabies in a few days; if it eats, death takes place a little more slowly, but it never exceeds eight or ten days. In the interval it manifests rabic symptoms. Confine the dog to his kennel, where he must be fed with precaution for at least twelve days. This had better be done under the supervision of a veterinary surgeon. If the dog lives after the time indicated, you may be assured that it is not mad. Meanwhile you have nothing else to care about than the wound caused by the bite. This should not be neglected. The saliva of a dog, even that of a healthy one, contains microbes foreign to the rabic virus, as those microbes might produce abscesses, and, in certain exceptional cases, septicæmia. In case the dog should go mad, come to me without delay, 45, Rue d'Ulm, at 11 A.M., where I will apply the preservative treatment for rabies."

LOUISE MICHEL.

Citoyenne Louise Michel, who has benefited, against her will, by the clemency of the President of the French Republic, in the form of a free pardon, has, since her exit from prison, been in a very excited state. She scarcely ever eats. She is evidently a monomaniac on the subject of revolution, and many people think that she is more fit for a lunatic asylum than a prison. One peculiarity in her may be noticed: she does not eat flesh, alleging as the reason that it comes from animals which have been killed.

The following changes in the staffs of the Paris hospitals are announced:—M. Mesnet takes M. Vulpian's place at the Hôtel Dieu, M. Troisier is appointed to the Saint Antoine, M. Cuffer to the Tenon, and M. Moizard to the Bicêtre. Prof. Gosselin has been elected Vice-President of the Academy of Sciences for the present year. In Bordeaux, M. Gervais has been appointed Surgeon to the Saint André Hospital.

Dr. Hayem has been elected a member of the Paris Academy of Medicine.

The following awards of prizes offered to the internes

Digitized by Google

resident medical officers of the Paris hospitals are announced:—Seniors: Gold medal and 1000 francs, Gilbert, of the Hôpital Saint Louis; accessit, silver medal, M. Queyrat, of the Hôpital Tenon. Juniors: Silver medal, M. Lejars, of the Hôpital Saint Antoine; accessit, M. Dumoulin, of the Hôpital de la Pitié.

Paris, Jan. 19th.

INTRAVENOUS INJECTIONS IN CHOLERA.

(*From a Correspondent.*)

DURING the epidemics of cholera which visited France in 1884 and 1885, among the various treatments adopted was that of intravenous injections, which had been proposed and practised about fifty years ago. The hospitals where this treatment was largely employed were St. Antoine, at Paris, and the naval hospital of St. Mandries, at Toulon. In the former this treatment was carried out during the epidemic of 1884 by M. Hayem, to whom we are indebted for any exact knowledge of the subject, and who embodied his results in an interesting little book. In the latter the treatment of M. Hayem was adopted by M. Spiller, during the epidemic which raged at that place last year, and his results formed the subject of a communication to the Académie de Médecine on Oct. 27th. This being the most recent attempt at a definite line of treatment on a large scale the results obtained are of undoubted interest. The history of the subject is briefly this: In the year 1830, during the epidemic of cholera at Moscow, Dr. Hermann first conceived the idea of preventing the thickening of the blood by means of intravenous injections, and his practice was followed by Dr. Tannichen, of that city, but without any lasting result. In 1832 intravenous injections were used in Scotland, especially by Dr. Latta, of Leith, and five successes were recorded out of fifteen cases in which the injections were used in patients in an apparently hopeless state of collapse. Many were the adverse opinions on this method of treatment, and it was regarded as requiring further extension and experiment before it could be reckoned as one of the means to be adopted in treating cholera. Practically, this was the state of the question when the cholera appeared in Paris in 1884; and M. Hayem, well known for his researches on the blood, set himself to restudy the question and determine the real value of this plan of treatment. His opportunities were ample, for his service was at the Hospital St. Antoine, situated in the low quarter of Paris, where the cholera made its chief ravages. He had already determined the fact that the injection of distilled water into the circulatory system of a dog up to the extent of from one-tenth to one-twentieth of its body weight had no effect beyond a passing hæmoglobinuria—that is to say, the amount of fluid in the vessels could be doubled without producing any unpleasant symptoms; and believing that the chief symptom in the algid stage of cholera is the altered condition of the blood due to the drain of fluid from the alimentary canal, he came to the conclusion that the right line of treatment was that of intravenous injection, as there was no hope of the restoration of fluid by the alimentary canal. According to this view, the phenomena of the algid stage of cholera were due to the state of the blood and the hindered circulation, and he proved by numerical enumeration of the blood-corpuscles that the fluid in the blood was much reduced—in fact he found an augmentation of 1,500,000 corpuscles per cubic millimetre, and from this he concluded that the total volume of blood was reduced by about one quarter. The fluid which he used for injecting was—

Distilled water	1000
Chloride of sodium	5
Sulphate of sodium	10

The amount injected varied from two litres to two litres and a half, and it was heated up to 38°C. Sometimes a second, and even a third, injection was made. The injections were only made in the gravest cases, a fact which must be borne in mind in looking at the results. Altogether the injections were made in ninety cases, of which sixty-three died and twenty-seven survived—that is to say, the percentage of cures was thirty. But the general impression left on the mind of the observer was that this mode of treatment was of great value, and "that intravenous injection in cholera constitutes the surest and quickest means of bringing about the reaction. It exposes the patients to no danger, and therefore it is the duty of the physician to adopt it as quickly as possible, before this terrible disease has determined grave lesions in the body which offer obstacles to a reaction. In a word, transfusion ought now to be considered as a regular and not exceptional method of treatment, which, rational and scientific as it is, promises to soon hold the first rank among the treatments of the choleraic collapse."

Such being the results obtained by M. Hayem, it was natural that the method found a further extension in the cholera epidemic of last year; and in the naval hospital of St. Mandries at Toulon, this method of treatment was adopted in fifty-five cases, of which thirty-seven died and eighteen recovered, or a percentage of cures of 33, which approaches the figure obtained by M. Hayem. The cases in which the treatment was tried were extremely grave, and it was adopted as a last resource, after other means had been tried, and when, in spite of these, the patients were in a state of collapse and asphyxia. The physician of St. Mandries was also convinced of the value of intravenous injections as a means of bringing about the reaction in the algid stage of the disease. Whatever be the views held as to the nature of cholera, it would appear that in intravenous injections a valuable means exists to combat the asphyxia and collapse, which must soon end in death, caused, as they appear to be, by the reduced condition of the blood and general dehydration of the whole body, which in its turn owes its origin to the intestinal flux. The opinion as to the origin of the intestinal drainage varies with the view we adopt as to the essential nature of cholera; a point into which I will not now enter.

Obituary.

WILLIAM BOUSFIELD PAGE, F.R.C.S.

WILLIAM BOUSFIELD PAGE died at his residence, St Ann's, near Carlisle, on January 6th, and by his death there has passed away a notable figure in the social and professional life of Cumberland. Born of a good Essex family in the year 1817, he early chose surgery as his profession, and with a view to its study entered the London Hospital as an apprentice to the late Mr. John Scott. There his ability soon gained him recognition, and he became a favourite pupil of his great master. In 1841 the edifice of the Cumberland Infirmary was complete, and it became necessary to appoint to it an acting staff. An able physician was readily found in the person of the late Dr. Barnes; but owing to difficulties with the local medical men—the memory of which is best forgotten—an influential deputation of county gentlemen, of which Bishop Percy was the head, entered into communication with Mr. Scott with a view to the selection of a competent surgeon for the institution, and he, being especially rich in the brilliancy of his pupils, offered the post first to Mr. Curling, then to the late Mr. Critchett, and next to Mr. Page. This association with those who have become cosmopolitan leaders in surgery stamps the early reputation and acquirements of him whose loss we deplore as being of the very highest. In an address delivered to the Medical Society of Carlisle last year, and of which he was the first president, he described how cold and cheerless his first winter journey to the North was, a forecast it may well have seemed to him in after-times of the character of his reception by his professional brethren, and of the then aspect of the institution to which he was appointed, for he found "it with an old man and woman occupying the kitchen, and otherwise every room empty." But he was daunted by neither. Patients soon came to him, and the empty hospital wards, with their comparatively aseptic atmosphere, soon became the location of many brilliant successes in surgery. In these times, when the use of anæsthetics is universal, when ovariotomy is justly regarded as one of the most beneficent of surgical operations, and when the results of excision of the knee have established its value as an operative procedure, it may seem strange that there was opposition to the introduction of any one of them, and especially strange that

Digitized by Google

obloquy should have attached to those who were bold enough in earlier days to carry them out. But so it was, and it is strong proof of the force and the faculty Mr. Page possessed when we find him a pioneer among those whose labours have rendered, by the establishment of the procedures referred to, our art richer and more beneficent, and suffering humanity still more largely our debtors. In THE LANCET of April 5th, 1845, appears the first notice of his success as an ovariotomist, and although within a comparatively short time (December, 1846) he published in the pages of the same journal an unsuccessful case, his hand was not stayed as an operator, and happily recovery followed in his succeeding operations. The case which terminated unsuccessfully was one of incomplete operation—extensive intestinal adhesions the cause of this; and in its result Mr. Page deplores, what even the vast experience of to-day has not altogether solved, the difficulty of diagnosing the existence and the situation of pronounced adhesions. Excision of the knee was also successfully carried out by him at a time when its reputation was of a very uncertain character; and the fact that in 1846 he had attained perfect results in two cases shows how alive he was to the advantages of conservative surgery. His predilection in this direction is further evidenced by a paper which was brought before the Medico-Chirurgical Society in 1850, and which we believe has a place in the Transactions for that year, as to the advantages in certain cases of disease of the os calcis of excision of the bone over the then almost universal treatment by amputation of the foot. The plan upon which he performed the operation is a good one, for it enabled him, had he in the progress of the excision found the other bones of the tarsus implicated, to have completed by the addition of the dorsal incision an ordinary amputation at the ankle. In the *Monthly Medical Journal* for February, 1847, there appears from his pen a most able, interesting, and instructive article on a case of spina bifida, in which the external tumour was successfully removed. Success in this operation, sometimes regarded as one of the triumphs of antiseptic surgery, was thus attained even in other days, and although the benefit which followed it was so great that its subject is now a woman in her prime, Mr. Page, with that sagacious character of mind which so distinguished him, defines in the most unmistakable way the small number of cases in which this method is applicable, the reason for adopting it, and the dangers which may follow its employment.

In such a sketch as this it is impossible to notice all the many ways in which he proved himself an able and enterprising surgeon, but those to which we have made reference may be regarded as typical of the method of the man: always interested in what was new and likely to be of benefit; always anxious to ascertain for himself the measure of this, and, despite the issue, to give his experience in the interests of his art. Lithotomy, of which he had many successful cases; acupressure in the arrest of hæmorrhage; the treatment of ununited fracture; the successful treatment of tetanus by the administration of aconite—on all these subjects he has left important records, which, though written long ago, may be studied now with interest and with gain.

What the profession thought of his labours is marked by the fact that in 1858 he was made a Fellow of the College, and that at even an earlier date the late Sir Benjamin Brodie used such influence as he possessed to induce Mr. Page to become a candidate for the post of surgeon to St. Mary's Hospital, a post which, singularly enough, is now held by his eldest son, Mr. Herbert Page. As, however happens to few men at so early a period of their lives, his time became too fully occupied to have leisure for literary work, for we soon find him the confidential adviser of the best families in Cumberland, and a recognised leader in his profession; and this position he maintained for nearly forty years, carrying on a family practice of the most select class, acting as a consultant over the greater part of the north of England and far across the Scotch border, always full of vigour, full of resource, and of wisest counsel. Added to all this, he had certainly one of the largest and widest connexions in the county as a railway surgeon; in this especial walk he began his work, as he did it in the Cumberland Infirmary, with the rise of the field for its exercise. The Lancaster and Carlisle Railway joined Carlisle to the southern systems, and Mr. Page was requested to act as medical adviser to its board of directors. This was a delicate post for the young surgeon to occupy, for it of necessity involved, not the mere dealing with traumatisms (with which he was perfectly familiar), but with that of compensation for injuries received—always, as we believe, a difficult task. With Mr. Page, however, there was no difficulty; the combination of abilities he possessed, and which we once heard well expressed by a man who was no mean judge of men, "that he was by nature gifted to be a good surgeon, a greater advocate, or a still greater financier," carried him through all exigencies, and in examining a "railway case," or in giving his testimony regarding it, it was felt that the opinion given was one that only a man gifted with perspicuity and wisdom could have formed. These gifts of perspicuity and wisdom, associated as they were with extraordinary shrewdness and ripe experience, made him much sought after as a consultant, and with medical men in the north there now arises the feeling that a wise friend and a prudent counsellor has passed from them. Educated at a time when the art of physical diagnosis was comparatively in its infancy, and when the training of the student was very different from what it is to-day, Mr. Page still managed to keep well abreast of the time, and to some of us it frequently seemed little short of marvellous how, without the use of such means as we of necessity employ, he with that acumen which the long years of work had given him, could make a more rapid and often a more accurate diagnosis.

Within a few days after his death the regret and sense of loss which had come to the profession in Carlisle and its neighbourhood found eloquent expression through Mr. Hull, the president of the local branch of the British Medical Association, who dwelt with emphasis upon the fact that one of the most successful endeavours in Mr. Page's life had been to better in every way the status of the medical man.

A man of iron physique, of strongest mental capacity, full of restless energy and of indomitable power of will, he yet possessed withal, and so largely, the better gift of a tender heart, that, directly through its influence, rest came to him, for he died from one of those mysteriously progressive forms of anæmia the starting-point of which seemed to lie in the shock of a heavy personal sorrow. Thus has closed a career of remarkable ability, singular usefulness, and extraordinary personal influence; and the thought comes to us sadly how much of wisdom, how much of knowledge, how much of the light collected by a life of experience and observation has perished with him, for the position he held never appeared more truly unique than it does now: it was one that no other man will ever hold.

THOMAS CECIL MORGAN, L.R.C.S. EDIN., L.K.Q.C.P.I.

NEW SOUTH WALES has sustained severe losses in the medical profession during the last six months; George Fortescue, Annesley West, and now Cecil Morgan, having joined the great majority. Cecil Morgan was one of a large family, and was born Jan. 13th, 1837, at Selsey Rectory, Sussex. Entering Trinity College as an engineering student, he changed his mind and turned his attention to medicine, qualifying in Edinburgh and Dublin in 1857 and 1858 respectively. He went to New South Wales almost immediately, and began practice at Gundagai, a town on the banks of the Murrumbidgee, where he remained for two years, returning to England in 1860 and entering the Army Medical Department. After some service in India he was invalided home, and was placed in charge of the ophthalmic wards at Netley. Retiring on half-pay, he was appointed resident surgeon at Moorfields, which office he held for some years, but the first warning of phthisis compelled him to seek a milder climate, and he went again to New South Wales. He was elected surgeon to the Sydney Hospital in 1878, and senior ophthalmic surgeon to the Ear and Eye Branch at Moorcliff in 1882. In 1883 he was appointed ophthalmic surgeon to the Goverment institutions at Parramatta and Liverpool, which office he held till his death on Nov. 24th, 1885.

Cecil Morgan's death leaves a great gap in the ranks of the profession in New South Wales. As a general operating surgeon he had few if any equals, and as an ophthalmic surgeon he was for years at the very head of his profession. As a teacher he was unrivalled. Unassuming and retiring almost to a fault, he did not make many friends, but those who were intimate with him, and were privileged to call him friend, knew well the gentle and amiable heart that beat under so quiet an exterior.

THOMAS WILLIAMSON, M.D.

ON the 30th ult. the death occurred at Leith from apoplexy of Dr. Williamson. Born at Greenock in 1815, the deceased received his medical education at Edinburgh University, and in 1836 obtained the degree of Doctor of Medicine, in the same year becoming a Licentiate of the Royal College of Surgeons, an institution of which he was elected a Fellow in 1857. He was one of the oldest members of the Medico-Chirurgical Society and of the Royal Society, Edinburgh. He practised for half a century in Leith, and was universally and deservedly respected and esteemed. For thirty years he was surgeon to the local hospital, and at the time of his death held the appointments of parochial medical officer and public vaccinator for the parish of South Leith and medical officer of health for the entire burgh.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 13th inst., and when eligible will be admitted to the Pass Examination:—

ANATOMY AND PHYSIOLOGY.—Sidney A. Bontor and Francis W. Tunnicliffe, St. Bartholomew's Hospital; Herbert V. Hickman and Edward H. Baldock, Guy's Hospital; George A. Ballingall, Edinburgh University.

ANATOMY ONLY.—Edmund R. Kavanaugh, Guy's and Westminster Hospitals; Albert B. Harman, Henry B. Falconer, and William J. Rugg, King's College Hospital; David T. Jones, Guy's Hospital; C. J. Paterson and Leslie M. Stocken, University College Hospital; Daniel J. P. McNabb, Newcastle and London Hospital; Edward J. Cross, St. Thomas's Hospital; Charles M. Leakey, London Hospital; George E. G. Metcalfe, St. Bartholomew's Hospital; Arthur G. N. Goldney, Charing-cross Hospital; Reginald F. H. Newton and Sidney D. Graham, St. George's Hospital; James D. H. Smyth and Robert B. Fergusson, St. Mary's Hospital.

PHYSIOLOGY ONLY.—Philip Johnson and George D. Parker, St. Bartholomew's Hospital; Henry B. Statter, Robert W. Rouw, and Arthur R. F. Evershed, Guy's Hospital; Hubert E. Blake, University College Hospital; Reginald Hedley, Bristol Medical School; Charles J. P. Hogarth, Melbourne and St. Bartholomew's Hospital; Ernest Carter and James L. S. Sherlock, London Hospital; Arthur Charles A. Lovegrove, Westminster Hospital; Robert R. Hatherell, St. Thomas's Hospital; Reginald Thorpe, St. George's Hospital; Alfred R. Sieveking, St. Mary's Hospital; Murdock Chisholm, McGill College, Montreal.

Passed on the 14th inst.:—

ANATOMY ONLY.—Frederick R. Hird and Arthur James Lambert, Leeds School of Medicine; Joseph Farrall Wright, Owens College, Manchester; William C. Costine, University College, Liverpool; Harry F. Devis, Bristol Medical School; Charles Graves, St. Mary's Hospital; Frank Osborne and Charles H. Andrews, St. Thomas's Hospital; Hubert A. Bray, King's College; Richard A. Smith and William W. Craig, University College; James V. Albert and George T. Mould, St. George's Hospital; Thomas H. Valintine, St. Bartholomew's Hospital; Albert E. Tebb and Richard G. Pollock, Guy's Hospital; John P. De Buriatta and Joseph R. Gallard, London Hospital; Reginald Roberts, Middlesex Hospital.

PHYSIOLOGY ONLY.—George Thorpe, Sheffield Medical School; Neal Nelson, Dublin; Edward Foxton, Kingston, Canada; Abraham J. Mener, New York; Henry W. C. B. Cave, Queen's College, Birmingham; William V. Tanner, Hugh C. Addison, and William D. Wells, King's College; George H. Thompson, Richard H. Wellington, and Charles S. Fisher, St. Bartholomew's Hospital; Norman Robinson and William H. Robinson, St. George's Hospital; Daniel F. Roberts, Manchester and Guy's Hospital, Joseph S. Bradish, Frederick M. House and Campbell R. Adams, St. Thomas's Hospital; Philip K. O'Brien and Arthur L. Fuller, University College; Edward O. Kingdon, St. Mary's Hospital.

The following gentlemen, having undergone the necessary examinations, were admitted Members of the College at a meeting of the Board of Examiners on the 18th inst.:—

Benson, Matthew, L.R.C.P. Lond., Wigan.
Burnett, Reuben, L.R.C.P. Lond., Onecote, Staffs.
Clarke, Edmund Wearne, M.B. Edin., Edinburgh.
Edye, John Simpson, L.S.A., Elgin-road.
Furrer, Edward, M.B. Toronto, St. Louis, Canada.
Hawley, Harold Heber, M.B. Toronto, Trenton, Ontario.
Logan, John Rannie, M.D. Toronto, Toronto, Canada.
McNabb, Daniel J. Patrick, L.R.C.P. Ed., Newcastle-on-Tyne.
Maloney, William Robert Nuttall, L.S.A., Melbourne.
Niven, George, M.B. Cantab., Greenwich.
Pickthorn, Alfred John, L.S.A., Wetherby-terrace.
Rendall, Percy John, L.S.A., Ladbroke-square.
Revely, Joseph Smith, M.B. Durham, South Shields.
Trask, John Ernest, Bath.

Admitted on the 19th inst.:—

Daniel, Frederick Edwin, Birmingham.
Dawson, Arthur Willan, M.B. Durham, Liverpool.
Evans, Williams, L.K.Q.C.P.I., Liverpool.
Facey, William Edwin, M.B. Cantab., Abergavenny.
Felix, Edward, L.R.C.P. Lond., Shirland-road.
Harvey, John Thomas, M.B. Edin., Victoria, Australia.
Hill, Alfred William, L.S.A., Adelaide.
Jolly, Sydney Blake, L.S.A., Lansdown, Bath.
Jowers, Reginald Francis, L.S.A., Brighton.
Male, Herbert Christopher, M.B. Edin., Stone, Staffs.
Montague, Arthur John Helm, L.S.A., Notting-hill.
Roach, George Ernest, L.S.A., Plymouth.
Sharman, Mark, M.B. Glasgow, Wellingborough.
Sugden, Edgar Brewitt, L.S.A., Hampstead.
Weaver, John James, L.S.A., Southport.
Wright Robert Wallace, Holland-road.

Admitted on the 20th inst.:—

Bates, George Tweedie, L.S.A., Bredwardine.
Billups, Percy Christopher C., L.R.C.P. Lond., East Dulwich.
Cavell, Herbert Bertram, L.S.A., Brook-street.
Cottell, Reginald James Cope, L.R.C.P. Lond., Cheyne-row.
Freeman, Ernest Carrick, L.R.C.P. Lond., St. George's-square.
Girvin, John, Mecklenburgh-square.
Hill, Joseph Shuter, L.R.C.P. Ed., Mecklenburgh-square.
Hughes, Morgan, Croydon.
Lyndon, Arnold, L.S.A., South Hampstead.
Otway, Henry Carrol, L.R.C.P. Lond., Kennington-park-road.
Rigge, John Arthur, L.S.A., Grays, Essex.
Roberts, Leonard, L.S.A., Bishopsyford.
Thorpe, Vidal Gunson, L.S.A., Camberwell.
Thomas, John, L.R.C.P. Lond., St. Peter's-street.
Volckman, Bernard, L.S.A., Stapleford, Notts.
Watts, Alfred Thomas Guy, L.S.A., Buckingham-palace-road.

The following gentleman passed in Anatomy on the 12th inst., but was omitted in the list published:—

N. Sisca, of Naples.

COLLEGE OF PHYSICIANS IN IRELAND.—At the January examinations the following obtained the Licences in Medicine and Midwifery of the College:—

MEDICINE.—Sydney Joseph Armstrong, William Vincent Barré, William Evans, George Fisher, Frederick Hall, Frederick Bernard Musgrave, Edward Nangle Smartt, Graves Stoker.

MIDWIFERY.—William Vincent Barré, Michael Patrick Dunlea, George Fisher, Henry Croker Garde, Frederick Hall.

The undermentioned were admitted Members:—

Ephraim MacDowell Cosgrave; W. Beatty.

SOCIETY OF APOTHECARIES.—The following gentleman passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received a certificate to practise, on the 14th inst.:—

Oakman, Joseph John, The Priory, Battersea.

The following passed the examination in the Science and Practice of Medicine, and received certificates to practise:—

Pisani, Lionel John, Rockmound-road, Upper Norwood.
Teasdall, Walter John, M.D. University of Victoria, Aurora, Ontario, Canada.
Thorpe, George, Stoke Newington-road.
Wilkin, Griffith Charles, Hyde-park-street.

The following gentlemen passed the examination in Arts on the 8th and 9th inst:—

FIRST DIVISION,
Winter, George Mitchell.
SECOND DIVISION.

Atkinson, J. C.	Knox, S. G.
Bonner, E. A.	Laver, P. G.
Buck, A. H.	Liversidge, A. A.
Chater, A. R.	Moore, H. St. B.
Davies, A. N.	Nall, J. F.
Denne, F. V.	Ouston, T. G.
Eastment, J. W.	Ringrose, E.
Flegg, F. A. M.	Savery, W. H.
Fuller, G. S.	Shepard, R. H.
Garrard, G.	Soltan, H.
Hern, G.	Whitehead, E. T.
Johnston, D. C.	Wood, G. E. M.
Kellman, J. C.	

Passed in Elementary Mechanics alone:—

Addie, A.	Lockyer, G. E.
Barnes, H. C.	Long, H. B.
Castellotte, B. A.	Meadows, A. H.
Dudley, A. D. P.	Rayner, D. C.
Dunn, R. A.	Sutherland, F. C.
Dryland, L.	Twynam, A. E. E.
Everett, E. W.	White, E. T.
Holden, G. B.	Garrett, J. H.
Jones, J. H.	Sheen, F. F. S.
Lang, E. J.	

ON the 20th inst. the death of a young man from hydrophobia occurred in Guy's Hospital.

Senores Sanchez Ocana, Candela, and Ledesma have been appointed Court physicians to the Queen of Spain.

EDUCATION OF THE BLIND AND THE DEAF AND DUMB.—The Queen has, on the recommendation of the Home Secretary, approved of the inquiry now being held by Royal Commissioners into the education of the blind being so extended as to include the education of the deaf and dumb and such other cases as would seem to require exceptional methods of educational treatment.

Digitized by Google

THE Hospital Sunday collection at Poole was held on the 10th inst.

IT is proposed to erect, by public subscription, a wing to one of the Melbourne Hospitals as a memorial to Sir Moses Montefiore.

AT the usual bi-monthly meeting of the Hackney District Board of Works on the 13th inst., Dr. Tripe, the medical officer of health, reported a severe outbreak of typhoid fever at the convent in Hassett-road, South Hackney.

DOVER HOSPITAL.—The annual meeting of this institution was held on the 20th inst. It was stated that the number of patients treated during the year was 4459, and the expenses had been kept well within the income, which had amounted to £1137.

QUEEN'S COLLEGE, BIRMINGHAM.—THE INGLEBY LECTURES.—The second of these lectures, "On Some Functional Disorders of Females," will be delivered by Dr. Wade, F.R.C.P., Senior Physician to the General Hospital, on Thursday, the 28th inst., in the Theatre of the College, at 4 o'clock. Subject: "Some Nervous Disorders."

NEW HOSPITAL IN HABANA.—The new hospital of Our Lady de las Mercedes, in the neighbourhood of Habana, is expected to be complete and ready for the reception of patients, who will be transferred from the old hospitals of St. Philip and Santiago. The new building is said to have been constructed in accordance with the most approved hygienic models.

BIRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL.—The Committee of this hospital have taken a piece of land in the centre of the town on which they intend building a new hospital. This will enable them to provide medicinal baths and beds for in-patients. For a long time past their present premises have been insufficient for the accommodation of the increasing number of patients applying for relief.

BOURNEMOUTH SANITARY HOSPITAL.—This new institution, which has been erected at a cost of £3900, was opened on the 13th inst. Accommodation is provided for six adults two children. Attached to the hospital is a very complete and apparatus for the disinfection of clothing by steam, and the sanitary arrangements are of a most satisfactory character.

ST. JOHN AMBULANCE ASSOCIATION.—A most promising centre has been formed in the Isle of Man. The inaugural meeting was held at Douglas on Monday, Jan. 18th. Surgeon-Major Hutton delivered an address on the aims and objects of the association. His Excellency Spencer Walpole, Lieutenant-Governor, President of the Centre, occupied the chair, and was supported by a considerable number of the local practitioners and committee-men.

NORTHERN HOSPITAL AMBULANCE.—The members of the Liverpool Junior Reform Club some time ago made a collection for the benefit of the deserving poor. The whole of the money was not expended, and a balance of £60 has just been handed to the treasurer of the Northern Hospital Ambulance Fund, on the condition that the ambulance is maintained at work during the whole of the present year, a condition which has been gladly assented to by the committee of the fund.

INSANITARY HOUSES.—In an action recently brought by a landlord to recover rent for a house, the defendant alleged that the insanitary state of the drains and the dampness of the building had caused such severe illness to himself and family that his medical attendant had advised his leaving it. The judge directed the jury that in the case of an unfurnished house there was, in letting it, no implied contract that it should be fit for the purpose of the person who took it. Judgment was accordingly given for the plaintiff.

THE FRENCH ACADEMY OF MEDICINE.—The names submitted by the Committee of the French Academy of Medicine, in addition to that of Sir Joseph Fayrer, who as we announced last week, was elected to fill the vacancy in the foreign corresponding members, were those of M. Thybaïdos of Athens, and Dr. Bateman of Norwich. The voting was as follows:—Fayrer, 43; Thybaïdos, 16; Bateman, 6. For the vacancy occasioned in the ordinary members, section of Therapeutics, by the death of M. Déchambre, founder and editor for some twenty years of the *Gazette Hebdomadaire*, and editor of the magnificent "Dictionnaire Encyclopédique des Sciences Médicales," five names were proposed—MM. Desmos, Dumontpallier, Hayem, Hallopeau, and Ferrand. The contest lay between MM. Hayem and Desmos, M. Hayem obtaining 44 votes against 38 given to M. Desmos. M. Hayem was therefore declared elected.

NORTH-WEST LONDON HOSPITAL.—A concert for the entertainment of the patients and friends of this hospital took place on the 14th inst. in the male ward of the institution.

SANITARY ASSURANCE ASSOCIATION.—At the Parkes Museum of Hygiene on the 20th inst., Mr. T. Roger Smith, Professor of Architecture, University College, delivered a lecture on "A Damp House." The chair was occupied by Sir Joseph Fayrer, and at the close of the address an interesting discussion, in which several members of the association joined, took place. On the 27th inst., a lecture on "Preventable Diseases" will be delivered by Mr. Jesset medical officer of health for Erith. These lectures are free to all, no tickets being required, and discussion is invited.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—The third of six winter evening conversaziones was held at this hospital on Friday, Jan. 15th. The surgeons present were Mr. Cowell and Mr. Hartridge. The following were among the cases shown: Glaucoma in a child aged fourteen; New Growth in Vitreous; Atrophy of Choroid; Dislocation of Lens; Large Hœmorrhage at Macula (three cases); Hœmorrhagic Retinitis; Optic Neuritis; Optic Atrophy; Congenital Crescent; Embolism of Central Artery of Retina; Conical Cornea, &c. The conversazione was largely attended.

LIVERPOOL MEDICAL INSTITUTION.—At the annual meeting, held on Thursday, Jan. 14th, the following list of officers, council, and microscopical committee was adopted:—President: Dr. J. Birkbeck Nevins. Vice-Presidents: Mr. Frank T. Paul, Dr. Burton, Dr. Alexander, and Dr. James Barr. Hon. Treasurer: Dr. F. J. Bailey. Hon. Gen. Secretary: Dr. Bernard. Hon. Sec. of Ordinary Meetings: Dr. W. Williams. Hon. Librarian: Mr. R. Williams. Council: Dr. J. Cameron, Mr. R. Hamilton, Dr. Harvey, Dr. Prytherch, Mr. Sheldon, Mr. H. O. Thomas, Dr. A. Davidson, Dr. Davies, Dr. Robert Gee, Mr. N. K. Marsh, Mr. D. Harrisson, and Dr. Wollaston. Microscopical Committee: Dr. Alexander, Dr. Barron, Dr. Braidwood, Dr. Briggs, Dr. Hyla Greves, Mr. G. Hamilton, Dr. Hicks, Dr. Logan, Mr. Rushton Parker, Mr. Frank T. Paul, Dr. J. Wiglesworth, and Dr. W. Williams. Auditors: Mr. C. G. Lee and Dr. H. Harvey.

MANCHESTER MEDICAL SOCIETY.—At the annual meeting of this Society on the 13th inst., a highly satisfactory report was read. The number of members is 242, an increase over the number of the previous year; and the balance in the hands of the treasurer is £253, as compared with £139 at the date of the last annual report. The following is a list of office-bearers for 1886: -President: Dr. J. Hardie. Vice-Presidents: Dr. Julius Dreschfeld, Dr. C. E. Glascott, Mr. G. W. Smith, and Mr. A. W. Stocks. Treasurer: Dr. David Little. Secretary: Mr. F. Armitage Southam, M.B., 242, Oxford-road, Manchester. Other members of Committee: Drs. C. J. Cullingworth, W. Young Martin, Siegmund Moritz, P. H. Mules, F. Morrish Pierce, C. Jeremiah Renshaw. T. Wemyss Rhodes, J. Ross, W. Japp Sinclair, and W. Yeats, Mr. E. Stanmore Bishop and Mr. A. Harry Young, M.B.

GREAT NORTHERN CENTRAL HOSPITAL.—The general council of this hospital met this week in the board-room of the institution, Caledonian-road, when Mr. C. T. Murdoch, M.P., who presided, reported that an eligible freehold site for the new hospital had been secured in the Holloway-road at a cost of £7500. Provision would be made for 150 beds, and the cost would not exceed £200 each bed. £2000 was necessary for the out-patients' department, and altogether £32,000 was required for the building, without furniture. It was estimated that £5000 would cover the expense of furniture and other charges. Towards the total cost £10,500 had been actually subscribed and promised, out of which the cost of the site had already been defrayed. Then there was a realisable asset in the long lease of the present hospital premises, which were ill-adapted to the purposes they had hitherto served. It was anticipated that the foundation stone of the new hospital would be laid during the ensuing spring.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

COUNSELL, H. E., M.R.C.S., has been appointed Resident Obstetric to Guy's Hospital.

DONALDSON, R. L. S., A.B., M.B., B.Ch.Dub., has been appointed Assistant-Resident Medical Superintendent to the Monaghan and Cavan District Lunatic Asylum, Monaghan.

FENTON, GEORGE, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Western Dispensary, Rochester-row, S.W., vice Francis Pearse, M.R.C.S., L.S.A.Lond., resigned.

HARSANT, J. G., M.B., B.S.Lond., has been appointed Resident Obstetric to Guy's Hospital.

MARSDEN, R. S., M.B., C.M.Ed., has been appointed Medical Officer for the Billington District of the Malton Union.

NIVEN, J., M.A., M.B., has been appointed Medical Officer of Health for the Borough of Oldham, vice Hill, deceased.

PHILPOTS, E. P., M.D., has been appointed Resident Physician to the Mont Dore, Bournemouth.

WALDO, F. J., M.A., M.D.Cantab., M.R.C.S., has been appointed Honorary Medical Officer to the Kensington Dispensary.

WARWICK, PERCY, L.R.C.P., M.R.C.S., has been appointed Medical Officer for the Second District of the Blything Union.

Births, Marriages, and Deaths.

BIRTHS.

BARLOW.—On the 18th inst., at Alma Villa, Dalston-lane, E., the wife of T. Carey Barlow, L.R.C.P.Ed., of a son.

BRUCE.—On the 17th inst., at City-road, the wife of Robert Bruce, M.R.C.S., of a daughter.

JOHNSTON.—At Spital-hill, Sheffield, the wife of Dr. Johnston, of a son (stillborn).

KIDD.—On the 15th inst., at 2, Cromwell-road, West Brighton, the wife of Leonard Kidd, M.R.C.S., L.R.C.P.Ed., of a son.

KILNER.—On the 12th inst., at Guildhall-street, Bury St. Edmunds, the wife of Charles Scott Kilner, M.B., of a son.

MOORE.—On the 19th inst., at Woodside, Keston, Kent, the wife of Norman Moore, M.D., Warden of the College of St. Bartholomew's Hospital, of a daughter.

ROSSITER.—On the 16th inst., at Cairo Lodge, Weston-super-Mare, the wife of George Frederick Rossiter, M.B.Lond., of a son.

THOMSON.—On the 17th inst., at Sinclair-road, Kensington, the wife of G. Crawford Thomson, M.B., M.R.C.S., of a son.

MARRIAGES.

CHAPMAN — MACKENZIE. — On the 14th inst., at 31, Regent-terrace, Edinburgh, by the Rev. P. Hay Hunter, Minister of the Parish of Elie, James Milne Chapman, M.B.Edin., M.R.C.S.Eng., of Inverness, to Eliza Georgina, daughter of the late A. F. Mackenzie, of Kessock, Inverness-shire.

FERGUSON—BOOTE.—On the 13th inst., at the Parish Church, Ashton-on-Mersey, James Mitchell Ferguson M.B., of Hounslow, to Jane Beatrice Margaret, elder daughter of Daniel Boote, of Ashton-on-Mersey and Manchester.

HUMPHREYS — DIGHT.—On the 13th inst., at Tollerwhelm Church, Richard Humphreys, M.B., C.M.Ed., of Grassendale, Liverpool, to Amy Mary, eldest daughter of John Dight, Esq., of Tollerwhelm, Beaminster, Dorset, and late of Martock, Somerset.

LINDSAY—ELLIOT.—On the 14th inst., at Brinsop Church, Herefordshire, W. Lindsay, M.R.C.S., to Anne Alison, elder daughter of the Rev. W. Elliot, Vicar of Brinsop.

MCGEAGH—MORICE.—On the 14th inst., at St. Stephen's, Paddington, London, by the Rev. W. S. Carter, R. T. McGeagh, M.D., Surgeon, A.M.S., to Ida C. Napier, eldest daughter of Morice Pacha, R.N., of Alexandria, Egypt.

VERITY—HOGG.—On the 13th inst., at Melbourne, Herbert Wilfred Steele Verity, M.R.C.S., L.R.C.P., fourth son of G. Hamilton Verity, Esq., to Agnes Emily, elder daughter of the late Captain W. Dinwiddie Hogg, D.A.C.G., H.E.I.C.S.

DEATHS.

FOWKE.—On the 17th inst., at Walton-on-the-Naze, Essex, Frederic Gustavus Fowke, M.R.C.S., formerly of Manor House, Charwelton, the eldest surviving son of the late Rev. Thorpe William Fowke, Vicar of Sudbury, Suffolk, in his 71st year.

KIRKMAN.—On the 11th inst., at Westergate, Melville-road, Redland, very suddenly, Joseph Thos. Kirkman, F.R.C.S., late of Horndean.

LEESON.—On the 13th inst., at Bath, Margaret Anne, the dearly-loved wife of J. R. Leeson, M.D., F.G.S., of Twickenham, after three days' illness of acute rheumatism and cardiac thrombosis, aged 36.

LITTLETON.—On the 16th inst., at his residence, Well-park, Saltash, Nicholas Littleton, M.R.C.S., Fleet-Surgeon R.N., aged 66.

MORGAN.—On the 14th inst., at Feltham, Middlesex, Charles Morgan, M.R.C.S., late of Bedford-row and Bedford-place, Russell-square, in his 86th year.

OSBORNE.—On the 13th inst., at Southwell, Notts, of concussion of the brain, John Henry Osborne, M.R.C.S., L.S.A.Lond., aged 64.

ROWBOTHAM.—On the 17th inst., at Woolwich, Wm. Rowbotham, M.R.C.S., son of the late S. Rowbotham, of Manchester, in his 67th year.

SMITH.—On the 14th inst., at Bishop's Lydeard, John Smith, M.R.C.S., L.S.A.Lond., aged 67.

WORKMAN.—On the 11th inst., at Titherley, Teignmouth, Charles John Workman, M.D., aged 46.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, January 25.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

SOCIETY OF ARTS.—8 P.M. Prof. H. S. Hele Shaw: Friction (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Thudichum: On the Theory of the Febrile Process, its accompanying Chemical Changes and the Modes in which it produces Death and Immunity.—Mr. Walter Pye: Pyæmia after Removal of a Sarcomatous Tumour from the Base of the Skull.

Tuesday, January 26.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 3.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. R. Stuart Poole: Naucratis.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Annual General Meeting.

SOCIETY OF ARTS.—8 P.M. Mr. Arnold White: The Importance of a National Scheme of Emigration for the Best Interests of British Commerce.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. William Ogle: Mortality in the Medical Profession.—Mr. Henry Lee: On the Tapetum Lucidum.

Wednesday, January 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

HUNTERIAN SOCIETY.—8 P.M. Dr. Braxton Hicks: (1) Note on a Condition of Uterine Displacement in which Pessaries are Contra-indicated; (2) A case of Cephalic Version in Arm Presentation.—Dr. Galabin: On the Relative Advantages of Axis-traction and Ordinary Forceps, and on the Mode of making Correct Axis-traction with Ordinary Long-curved Forceps.

SOCIETY OF ARTS.—8 P.M. Mr. Henry Davey: Machinery in Mines.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown. Address by Mr. Lawson Tait.

Thursday, January 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Chandler Roberts-Austen: Metals as affected by Small Quantities of Impurity.

SOCIETY OF ARTS.—8 P.M. Mr. Wm. Bottomley, jun.: The Magnetism of Ships and the Mariner's Compass.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Dr. Thomas Reid: (1) Polarisation Spectroscope for Achromatopsia; (2) the same for determining the neutral points in Dichroic Vision; (3) A Perimeter for Colour Vision; (4) Ophthalmoscopes adapted for the Electric Light.—Mr. E. Nettleship: Fatal Meningitis after Enucleation.—Mr. Priestley Smith: Primary Glaucoma in relation to Age.—Mr. W. H. Jessop: On Herpes Ophthalmicus affecting the eye.—Mr. G. L. Johnson: (1) Atrophy of Iris, &c., following a blow on the head; (2) Conical Cornea improved by Stenopaic Glasses.—Mr. W. Lang (for Dr. J. W. Barrett): New Microtome.—Mr. H. Juler: Refraction Ophthalmoscope arranged for the Electric Light.—Dr. C. E. Fitzgerald: A new Instrument for facilitating Refraction Tests.—Mr. W. H. Jessop: A new Pupillometer.—Mr. W. Adams Frost: A new Model showing the Movements of the Eyes.—Mr. G. Hartridge: (1) Glaucoma in a girl aged fourteen; (2) Small Lenses.—Mr. R. M. Gunn: (1) Optic Atrophy after Wound of Orbit; (2) Amblyopia from Bisulphide of Carbon; (3) Result of Operation on Eye damaged by severe Sympathetic Disease.—Living and Card Specimens at 8 P.M.

Friday, January 29

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Sir Wm. Thomson: Capillary Attraction.

Saturday, January 30.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

MIDDLESEX HOSPITAL.—Operations 2 P.M.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Archibald Geikie: The History of Volcanic Action in the British Isles.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"FROM DARKNESS TO LIGHT."

UNDER this heading a Liverpool contemporary recently published a sensational account of the recovery of sight by a man who was under the care of Mr. Emrys-Jones, of Manchester. The account was garbled and inaccurate, and we are glad to learn that Mr. Jones has promptly and publicly disclaimed all connexion with the production. The profession has always rightly set its face against the parade of medical technicalities in the lay press, an attitude which we venture to hope will be long maintained.

Hon. Surgeon-Major.—We think not. A bearer corps composed of undrilled men would be worse than useless.

"WAKES AND THE SPREAD OF SMALL-POX."

To the Editor of THE LANCET.

SIR,—Your Liverpool correspondent gives in your last issue (p. 133), under the above heading, some interesting particulars of a successful prosecution under Sect. 126 of the Public Health Act of 1875, but does not state explicitly the nature of the act of the "exposure" upon which the proceedings were based. If, as he seems to imply, the conviction was for holding a "wake" upon an infectious case in a private house, it is an important precedent. In somewhat similar circumstances I have always had to prove to the satisfaction of the magistrates that the place of exposure was, in the words of the section, a "street, public place, shop, inn, or public conveyance." The practice of holding "wakes" in such cases cannot be too strongly condemned; but even in towns where this foolish custom is happily rare, instances are of constant occurrence in which there is the most culpable and reckless exposure of infected persons, but which are, as it were, privileged by the well-meant limitation of the scope of the section.

I am, Sir, yours faithfully,

B. A. WHITELEGGE, M.D.

Nottingham, Jan. 16th, 1886. Medical Officer of Health.

"HYPERIDROSIS."

To the Editor of THE LANCET.

SIR,—In reply to "Enquirens," who asks in your last issue for a remedy in a case of hyperidrosis, I would venture to suggest the use of fluid extract of coca, to look well to the alimentary tract from beginning to end, and to observe if the saliva is acid, as also the perspiration. I have used nitro-muriatic acid with a certain amount of success when the saliva gives an acid reaction and when there has been excess of perspiration. If the above suggestion fails, I would first see that the liver was unloaded and acting well, and then administer hypodermic injections of quinine.

I am, Sir, yours faithfully,

Jan. 20th, 1886. DOUBLE QUAL.

NEGRO MORTALITY IN THE UNITED STATES.

THE statistics of mortality in the United States seem to show that the negro question—so far as it still exists—is likely to settle itself without extraneous interference. In six cities the negro death-rate has been kept quite distinct from that of the white population, and the result is certainly striking. In Louisville the white death-rate is 20·04 per 1000; among the blacks the death-rate is 34·76. In Washington it is 17·80 for whites; 35·45 for blacks. In Richmond, 19·12 and 31·95. In Baltimore, 22·71 and 37·61. In New Orleans, 25·41 and 35·61. In Charlestown, 25·76 and 45. Thus, in two of these cities the mortality among the blacks is almost exactly double that among the white population; in the others it is more than a third greater. If this rate of mortality be kept up, by the end of another century the black man will have almost disappeared off the face of the North American continent.

C. V.—The case is very interesting, and one not unlikely to arise, till the risk of high temperatures and the sometimes amazing efficiency of cold water in reducing them are better understood by the public. We fear there is no legal way out of our correspondent's difficulty. The fee is of the nature of an honorarium, which the bye-laws of the College forbid to be made the subject of a legal process. The satisfactory thing is that our correspondent and his consultant did what was right, and what they would have been blamed for not doing if their conduct had been submitted to any competent professional judge. It is quite likely that the father will come to realise this after a time, and a little allowance should be made for the difficulty of the parental and non-professional mind realising that all the distress, and death itself, were the result of a burning up of the body, which in many instances has been arrested by the cold bath. We should be glad to hear further from our correspondent.

Dr. Rummo (Naples).—We cannot exchange.

THE ADMINISTRATION OF THE CORONER'S "'QUEST."

To the Editor of THE LANCET.

SIR,—It is to be sincerely hoped that during the forthcoming session the Legislature will have sufficient time at its disposal to introduce a Bill for the better working and administration of the coroner's "'quest." The existing Acts are anything but a security and protection for human life. In this division of the county no fees whatever are paid either to jury or to witnesses. Half-a-crown is paid for the hire of the inquest-room, and, with the exception of the coroner's travelling expenses and the medical fees, the cost of an inquest amounts to a few shillings only. I could quote many cases that have lately come under my immediate notice where inquests should have been held. I will not, however, unnecessarily trespass upon your space, but will give one case as an example.

I was called on the 5th inst. to the Selling railway station, and found a healthy-looking woman of forty in the waiting-room, holding in her hand the fare which she was about to tender at the ticket-office, when, without a moment's warning, she fell down and expired without a murmur. About two hours elapsed before a county constable could be found, and when he arrived he was sent to communicate with the coroner. The constable did not search the woman, nor did he in any way examine her, but simply took my letter to the coroner, in which I reported that "the cause of death was quite unknown." The coroner sent a verbal message to the effect that a post-mortem examination or inquest was unnecessary.

After a case like this, it would appear that in certain instances a coroner's "'quest" is useless. If a coroner can sign the cause of death upon the report of a county constable, a medical man might say that he was justified in certifying the cause of death upon the statement made by a well-educated but unqualified assistant. What was the cause of this poor woman's death I cannot say. Whether she took cyanide or died from aneurysm, &c., I do not know.—I remain, Sir, yours truly,

Faversham, Kent, Jan. 11th, 1886. CHARLES CHITTENDEN.

"JEMIMAS."

To the Editor of THE LANCET.

SIR,—In answer to "One of your Non-professional Readers," will you allow me to say that "jemimas" may be bought at Thornton's, Boar-lane, Leeds. The price is 7*s.* 6*d.*, not 7*s.*, as I stated, and by parcel post 8*s.* In my original letter the address of the shop was not given, as I supposed that the snow-boots referred to were to be had in most large towns.

I am, Sir, yours faithfully,

Leeds, Jan. 18th, 1886. T. PRIDGIN TEALE.

SEA VOYAGE FOR INVALIDS.

To the Editor of THE LANCET.

SIR,—Can any of your readers inform me if there is any good work published which would give information on the treatment of delicate persons on a long sea voyage? Or I should be obliged to any who could inform me whether a sailing vessel or steamer is preferable for such persons undertaking a voyage to Australia, and the difficulties likely to be encountered in each case. I am, Sir, yours faithfully,

I am, Sir, yours faithfully,

...m. 16th, 1886. G. T. THOMSON, M.D.

FOUR PERFECT ARMS AND LEGS.

A WOMAN at San Vicente, in Spain, has lately been delivered, after a very difficult labour, of a female child, perfectly formed, but with two perfect supernumerary arms springing from the scapulæ, and two corresponding supernumerary legs arising from the ischia. The supernumerary limbs move with the others. The child is in perfect health; but the father, not, of course, liking such a monstrosity for a daughter, proposes to take the child to Barcelona, to see whether the surgeons of the medical faculty there will accept the responsibility of removing the redundant limbs.

Quæritor.—We advise no such communication. Time and experience may induce a better estimate of the value of medical service. But the dignified course is absolutely to leave the patient to his own freedom.

PRURITUS AND COFFEE-DRINKING.

To the Editor of THE LANCET.

SIR,—In several of your late issues the connexion between the habitual use of coffee and pruritus ani has received attention from various correspondents. That this is one of the effects of the practice has long been known to me; and I would suggest that it may arise from the effect upon the liver which coffee is popularly supposed to have, and that is, of rendering it inactive. But there are also in coffee constituents some of which may give rise to this symptom. There is a highly flavoured essential oil which gives its characteristic odour to the urine, while at the same time some of the colouring matter is excreted by the kidneys. Possibly coffee may be like other spices which produce irritation about the anus. My chief object in writing to you, however, is to inform your correspondent, "A. W." (THE LANCET, Jan. 9th, p. 92), that there is a remedy for pruritus ani which I have found to give the greatest relief—viz., to lightly smear the anus and its immediate neighbourhood with the glycerine of carbolic acid of the Pharmacopœia, and then gently wipe it off with a soft handkerchief, next morning washing it with good glycerine soap and warm water. A few days of this treatment will, in my experience, effectually relieve this distressing symptom. Probably it is some of the extractive matters of coffee which give rise to the symptom complained of; for I do not find that the administration of caffeine in large doses for a considerable time produces it, which is a fortunate circumstance in the matter of so useful a drug as caffeine.

I am, Sir, your obedient servant,

Leamington, Jan. 11th, 1886. THOS. W. THURSFIELD, M.D.

SPINA BIFIDA.

IN the report of Mr. Clutton's case at the meeting of the Clinical Society (THE LANCET, Jan. 16th, page 108, twenty-second line from top of second column) the word "running" should have been omitted.

MEATH HOSPITAL, DUBLIN.

To the Editor of THE LANCET.

SIR,—With your usual kindness, would you allow me to mention through your columns to the many readers of THE LANCET who were students at the Old Meath Hospital, Dublin, that I am at present engaged in tabulating in book form the names, addresses, period of study, qualifications, and present appointments of all old students of the hospital, no matter in what part of the world they are at present located. In order that my compendium should be complete, if those who see this letter would kindly forward to me as soon as possible the desired information, it would be esteemed as a very great favour. To save trouble, a postcard will in most cases be sufficient, provided the name and address are clearly and plainly written.—I am, Sir, yours truly,

D. HEPENSTAL ORMSBY, M.D., F.R.C.S.,
Surgeon to the Meath Hospital and Co. Dublin Infirmary.

4, Merrion-square West, Dublin, Jan. 16th, 1886.

SEPARATE EXAMINATION IN MECHANICS.

To the Editor of THE LANCET.

SIR,—A student who has passed an examination recognised by the General Medical Council, but which does not include mechanics as one of its subjects, can obtain a separate examination here in that subject, and a certificate of having passed it will be accepted by the General Medical Council for registration. "An Anxious Parent and a F.R.C.S." need not, therefore, send his son so far from home for examination in mechanics, as is suggested by your correspondent, "Wm. M. D. G.," in your issue of the 16th inst.—I am, Sir, your obedient servant,

T. PEREGRINE, M.D.,
Secretary to the Board of Examiners.

Apothecaries' Hall, Blackfriars, E.C., Jan. 19th, 1886.

VOLUNTEER CHOIR.

To the Editor of THE LANCET.

SIR,—The London Diocesan Council for the Welfare of Young Men are instituting a volunteer choir for the services on Sunday afternoons at St. Martin's-in-the-fields. Among the students at the London hospitals there are no doubt many who would volunteer to join, and the Secretary, Mr. J. Johnstone Bourne, Northumberland-avenue, will be pleased to receive their names and give any further particulars required.

I am, Sir, yours obediently,

Arma House, Onslow Gardens, Jan. 11th, 1886. EDGAR P. STRINGER.

NITRO-GLYCERINE.

Mr. Foy writes that the necessity of the profession having some elected members on the Medical Council is fully proved by the action of that body in the preparation and editing of the recent edition of the Pharmacopœia. Our correspondent states that of new drugs which the profession has adopted, nitro-glycerine is perhaps the most largely and generally used, and it is desirable that it should be prepared in a form easily carried, quickly obtained, keeping well, readily administered, and inexpensive. These advantages, Mr. Foy contends, are obtained in a greater degree in an alcoholic solution than in the chocolate creams, and, in his opinion, this is the preparation that should have gained the approval of the Council.

Fidelis.—Certainly so. B's successor has doubtless bought the practice subject to the engagement of A to B not to practise. B's having become qualified only enhances his moral obligations.

TREATMENT OF A SPLIT FINGER-NAIL.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent, "Rus," who asks for advice as to the treatment of his split finger-nail, I would suggest the following plan, which I have tried with complete success in a similar case:—A groove, one-eighth of an inch long and parallel to the root of the nail—i.e., at right angles to the split—should be made with a knife or small file in the sound portion of the nail, between the root of the nail and the split. This will form a barrier which the split cannot pass, and when the groove grows to the free margin of the nail there will be no further tendency for the trouble to recur.

I am, Sir, yours truly,

Upper Berkeley-st., W., Jan. 16th, 1886. R. C. PRIESTLEY, M.R.C.S.

SIGNS OF FŒTAL DEATH.

To the Editor of THE LANCET.

SIR,—The absence of a certain sign of fœtal death whenever the question of version and forceps comes up is acknowledged to be one of the weak points in obstetrics. Now, I would suggest that the hand should be introduced into the uterus and placed on the fœtal heart. By this means absolute certainty would be attained, and many a mother saved from the dangers of forceps, and especially from the dangers of version where the waters have drained away. Of course, if no fœtal heart movements were felt, then perforation would be resorted to. I hope the above suggestion will prove useful when there is any doubt as to the death of the fœtus. I am, Sir, yours truly,

ALF. BELL WHITTON, M.B., C.M.Edin.

Maternity Hospital, Glasgow, Jan. 18th, 1885.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Godlee, London; Dr. Brailey, London; Dr. Hassall, San Remo; Mr. Emrys-Jones, Manchester; Mr. J. H. Morgan, London; Dr. Stanley Haynes, Malvern; Mr. Ford, London; Mr. Stanley Nelson; Dr. Wilkinson; Mr. F. W. Allwright, Wooburn; Mr. A. J. Smith, Dublin; Mr. W. H. Browne, Aldbrough; Dr. Whitelegge, Nottingham; Mr. C. Macalister, Manchester; Mr. B. Bast, London; Dr. Thomas, Sheffield; Mr. C. S. Lectures
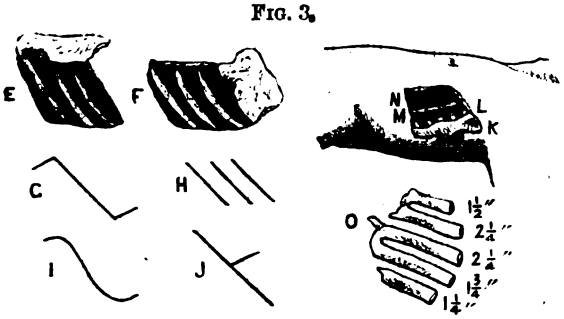
ON THE
SURGICAL TREATMENT OF EMPYEMA.

Delivered at the Hospital for Consumption and Diseases of the Chest, Brompton.



By RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL, AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.

(*Concluded from page 145.*)

If the operation be decided upon, the surgeon must, after ascertaining the size of the cavity, make up his mind as to the method of exposing the ribs to be removed. One way of doing this is by means of incisions parallel to the ribs. Through one such incision, carried through all the soft parts down upon one rib, portions of one or two others may be removed. I have not employed this method myself, but feel sure that, if it be decided upon, it is wise first to expose one of the ribs bounding the sinus and take a portion of it away, as it is clear that no exploration with any form of probe can give anything like such an accurate idea of the cavity to be dealt with as can be obtained by the introduction of the finger. After this has been done, the method of several incisions may, if desired, be employed. I have generally employed one of the flap operations indicated by the accompanying diagram (Fig. 3)—i.e., either turning one flap upwards or

FIG. 3.

The above illustrates different methods of performing Estlander's operation. E, Three ribs exposed by a flap turned forwards. F, Three ribs exposed by a flap turned upwards. G H I J, Other incisions which may be conveniently employed. The figure to the right was taken from C. W. (Case 5, *vide infra*). K, Flap turned backwards. L, The ends of the five ribs divided. M, Edge of thickened pleura which has been cut away. N, Cavity laid open. O, Parts of fifth, sixth, seventh, eighth, and ninth ribs removed, showing how the ends became rounded off and sometimes joined together after a previous removal of portions in front of those excised at this operation.

inwards, or making two flaps by means of a T-shaped or zig-zag cut. In doing this the muscles may be left adherent to the bones, or turned up with the flap, according to the position operated upon. For instance, it is more convenient to turn up the pectoralis major with the flap, than to make several cuts across its fibres; but, on the other hand, if one or two ribs only are to be removed in the axilla, and the surgeon does not intend to remove the periosteum and pleura, the serratus may conveniently be left behind, a skin flap only being turned aside. The parts over the ribs are often very vascular, and it is not uncommon to meet with hæmorrhage, which in a child is rather alarming, especially in the weak anæmic condition it will probably exhibit. The hæmorrhage takes place from a large number of small arteries along the intercostal spaces. It is not worth while to spend much time in attempting to secure these vessels. It is very difficult to do so, and after the rib has been removed they cause no further trouble. After the periosteum has been removed from the outer surface of the whole length of the rib to be excised with a square periosteum elevator, a blunt and slightly curved one with a rounded end is slipped beneath the rib, and it is found in these old cases that the dense pleura and periosteum are separated much more readily than the thinner corresponding structures in a recent case. Generally, when the instrument has been introduced at one point, it can with a firm pressure upwards and downwards at once clear the whole of the required length of rib. This may then be divided, either in the middle of the exposed portion, or, as I am in the habit of doing, at one end of it. By grasping the detached end the other is then divided without difficulty. It is very seldom that a rib even of a strong man cannot be divided with cutting pliers—either an ordinary pair, bent on the flat at the joint, or else such a pair as I showed you at the last lecture. But in case of difficulty the surgeon may be provided with a small saw, made on a convenient pattern. It is long, however, since I have used any instrument except cutting pliers for this purpose. Having, then, removed a sufficient length—three four, five, or more inches—of the rib from what is considered a sufficient area of the chest wall, the object being to render as far as may be possible the whole of the part that has to fall in pliable, or, in other words, to make the ends of the excised portion of rib correspond as nearly as possible with the anterior and posterior limits of the cavity it is intended to close, the question next arises as to what is to be done with the periosteum and pleura. The great rapidity with which a rib is reproduced if the periosteum be left soon puts a stop to the process of contraction; and, indeed, it appears that in some cases a large mass of callus is developed, forming a complete bony wall, which is, if possible, more incapable of yielding than the closely imbricated ribs which it has replaced. It is wise, therefore, to remove as much as possible of this thickened periosteum and pleura, so as to leave, in fact, a great gaping hole instead of a cavity with a small outlet. This may be thought to be a serious undertaking, and I used to be in the habit of applying several ligatures to the proximal portion of the mass before removing it. Subsequent experience, however, shows that this precaution is not necessary; for though the superficial vessels bleed freely, little or no trouble is given by the trunks of the intercostal arteries themselves. I have often removed some square inches of this dense material without having to ligature a single vessel; and if it be removed by snipping gradually away with curved scissors, the vessels, if any are met with, are easily secured directly they are divided, and no hæmorrhage of consequence occurs. The further back the vessels are divided, of course, the larger they are. The surgeon now has the opportunity of making a thorough investigation of the cavity. It is not likely that the interior will bleed much, and he may, if he thinks fit, adopt means for stimulating, and what is more important, purifying the interior. For this purpose many scrape the interior with a Volkmann's sharp spoon, and consider it a very valuable proceeding. I have done it several times, but it is very difficult to distinguish any good that arises from this procedure from that which arises from the operation itself. Its chief use, probably, is in removing the septic surface of the pleura, and preparing it for the application of the antiseptic materials to be next applied. I cannot help feeling that it is rather a rough proceeding, and when we reflect that the spoon may be scraping over the surface of the pericardium, and may be passing very close to important branches of the vagus and sympathetic, and also that the amount of good to be obtained is, to say the least, problematical, I think we may safely urge caution in its exercise.

While speaking on this subject I must make a divergence to say a few words concerning the occurrence of sudden death during the injection of the pleural cavity. Injection of the pleura was, I believe, much more freely practised at one time than it is at present. It may be used for two purposes, one to diminish the fetor of the discharge, the other to stimulate the granulations to a more healthy action. The latter object I conceive to be altogether futile and imaginary, and indeed I believe that as regards the development of granulations it is positively mischievous, tending to break down and destroy those that already exist. As regards the purification of the surfaces, injection is no doubt sometimes very useful, and indeed sometimes essential to the comparative comfort of the patient—that is, in those cases where it is hopeless to attempt a closure of the cavity and the system is being

Digitized by Google

poisoned by the putridity of the discharge. We sometimes practise it here, and are in the habit of employing a method which is perhaps the safest that can be devised:—A glass vessel with a perforation near the bottom, from which passes a caoutchouc tube, is filled with a solution of iodine of a pale sherry colour. To the caoutchouc tube is fitted a piece of gum-elastic catheter small enough not to fit tightly in the sinus. The caoutchouc tube is compressed by a pair of bull-dog forceps while the catheter is being introduced into the chest. When this is done the pressure is relaxed, and the bottle is raised very slightly above the level of the patient's body. In this way it is impossible to exert too great pressure inside the cavity, for the pressure itself is slight to begin with, and, moreover, the fluid runs out alongside the catheter as soon as or before the cavity is filled. The only sources of danger are that too large a catheter may carelessly be employed, or that the bottle may thoughtlessly be raised too high. But at the same time it must be remembered that a considerable number of cases are on record where the injection, though it has been perhaps frequently repeated without serious consequences, has led to sudden death or the most alarming symptoms. One such case I saw years ago at University College Hospital; it was that of a small boy, whose cavity, reduced at the time to very small dimensions, was daily washed out, by means of a syringe, with a weak solution of iodine. The boy used to sit up while it was being done, and one day during the process he suddenly died, and we were not able at the post-mortem examination to find any cause whatever for the disaster. The cavity was small, surrounded by thick fibrous walls, and there was no sign of thrombosis to be discovered. In the tenth volume of the Clinical Society's Transactions (1876) is a paper on this subject by Dr. Cayley, detailing a case in which the practice was to withdraw the pus through a cannula and then to inject about four ounces of iodine solution, repeating the process several times. On one occasion six ounces were being injected into the cavity, which at the post-mortem it was found would hold twice that quantity, when the patient suddenly became deadly pale, with slow pulse, dilated pupils, and gasping breathing. This gave place to profound unconsciousness, flushed face, rapid pulse and respiration, and right-sided convulsions. The temperature rose to 107°, and he died sixteen hours after the injection; but the necropsy revealed nothing to account for the death. Dr. Cayley refers to several other cases more or less similar, some ending fatally, and others recovering from the most imminent danger; and I well recollect at the discussion which followed not a few speakers referred to cases which had come under their own cognisance in which similar results had followed. Now, though two explanations have been hazarded for these phenomena, according to which they may be attributed either to thrombosis or to reflex irritation, it must be owned that we are altogether without a satisfactory one. It does not appear to depend upon the fluid employed, for it has occurred when carbolic acid, iodine, or even simple water were being used; it does not depend upon the side of the chest affected, for some cases have been left-sided and others right; and it has always happened in cases in which the injection had been frequently practised before without serious consequences. We are therefore at present left with the fact that a serious issue may any day follow what appears to be the simplest of surgical procedures. It is this which makes me not only avoid injections except when it seems urgently indicated, but also rather shy of resorting to very heroic measures in the way of scraping the pleura. It is true that I have frequently mopped out the surface with a strong solution of chloride of zinc (forty grains to the ounce), and have not seen any evil results follow; but I always do it with a degree of dread, and endeavour to apply it as gently as possible—not with a syringe, but with a piece of lint or a sponge.

Having, then, done all that seems safe or wise in the way of purification (and amongst the simplest and safest means I must not omit to mention the thorough application of iodoform to the surface), the next thing is the introduction of the drainage-tube. Bearing in mind what has been said about the method of closure of the cavity, it is clear that the tube must be placed as high up in the cavity as possible; that is, at the upper rather than the lower part of the opening that has been made. It may sometimes seem advisable, in order to facilitate this, to stitch up the lower part of the wound, as was done in the case of J. H. (Table II., Case 4). In this case it will be advisable to introduce a small and temporary drain below the part which is sutured, while the main and more permanent tube comes out above. A few stitches may often be introduced into the wound with advantage.

I will now, in conclusion, give a very brief account of the cases in which I have endeavoured to follow this line of treatment; but I must repeat a doubt as to whether it has been in all of them so fully carried out as the necessities of the cases may have required. This, perhaps, accounts for the comparatively unsatisfactory results which I have to record—namely, that only one of the cases is at the present moment actually healed, and that only after the making of a second posterior opening by another surgeon. For all that, I think it highly probable that some, if not all except J. H. (Table II., Case 4) and J. E. (Case 1), who will probably never be completely cured, have a very good chance of permanently closing in the course of time. In consequence of what has been done, all of them (with the exception, perhaps, of Alfred D., Case 7, who was not in a very bad state before, and Jane E., Case 1) have been very markedly improved as regards their general condition, so that, even if no more good should follow, I feel quite encouraged to continue this line of treatment, hoping to carry it out yet more efficiently in future cases with confidence of thus obtaining better results.

CASE 1.—Jane E——, aged seven, a delicate, anæmic, emaciated child, is under my care at University College Hospital. She has an empyema of very old standing, and has marked clubbing of fingers and nose. In August, 1884, there was a sinus discharging putrid pus below the left nipple, and reaching up into a cavity which occupied the front and side of the left chest, and extended to the right of the sternum. There was but little deformity behind, but a sharp ridge in front, parallel with the sternum. On August 12th, 1884, I removed from two to three inches of the third, fourth, and fifth ribs, including the whole of the cartilage (the length may have been greater). This has caused a great improvement in the deformity; but the cavity on the right of the sternum could never be satisfactorily dealt with as it lay immediately in front of the arch of the aorta. She had a slight attack of pneumonia while under treatment, but it soon passed off; she is now (October, 1885) in fair general health; but the sinus continues to discharge fetid pus, and, in fact, it cannot be said that she is much better for the operation except as regards the deformity.

CASE 2.—Harriet S——, aged eleven, came under my care at University College Hospital in August 1883, with an old empyema on the right side of seven years standing, and a sinus below the angle of the scapula leading to a small cavity. There was much flattening of the chest and clubbing. Parts of the eighth rib (2½ in.), ninth (1½ in.), and tenth (¾ in.) were removed. The wound rapidly closed and a mere sinus remained, but when last seen, several months after, it had not completely closed.

CASE 3.—Miss C——, aged four, had an empyema of two years' standing. I saw her with Dr. Barlow in April, 1885. There was a very imperfect opening below and outside the nipple on the left side leading to a cavity, which reached the apex of the pleura, but did not extend to the back. I removed pieces of two ribs (fifth and sixth or sixth and seventh) and left a large gaping wound into the cavity, but I hear that it has not yet completely closed, though the child's general health has much improved.

CASE 4.—James H——, aged ten, was admitted to the Brompton Hospital on Dec. 28th, 1883, with a left empyema, which had lasted for five years. He was pale and anæmic, with much clubbing and extraordinary contraction of the chest. There were two fistulous openings, one near the nipple, and the other in the second space near the sternum, from which there was a daily discharge of from one to two ounces of fetid pus. On Feb. 7th, 1884, I removed pieces of the fifth, sixth, seventh, and eighth ribs, with the subjacent pleura, opening into a cavity, containing six to seven ounces of fetid pus. The cavity involved practically the whole pleura. The result of this was an almost complete closure of the lower part of the cavity, a mere sinus leading up to the dome of the pleura. Sponge-grafting was then tried, but failed. On July 11th, 1884, several more pieces of rib were removed, some probably from those previously excised, some from the third and fourth. This operation resulted in a more complete closure of the lower part, and as there seemed no prospect of the upper part closing, on Nov. 20th I made with great difficulty an opening in the first intercostal space, and introduced a straight celluloid tube, two

Digitized by Google

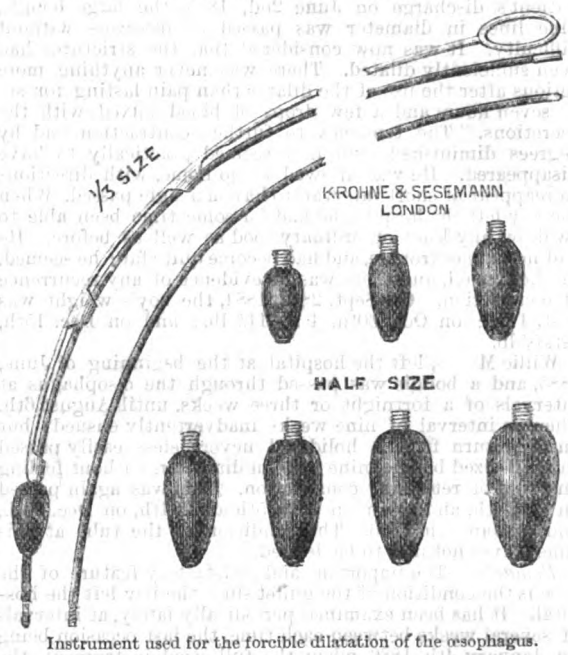
inches and a half long, into the upper part of the pleura. This the boy still wears, and will probably have to continue to do so. All the lower openings are now closed, and his general health when he left the hospital was excellent.

CASE 5.—Charles W——, aged twenty-five, was admitted more than two years ago into University College Hospital with a chronic empyema, which was opened by an incision in the right axilla in March, 1883. In May, 1884, Mr. Marshall removed portions one inch long of the sixth, seventh, and eighth ribs, opening freely a cavity containing about eight ounces of pus. In March, 1885, he had still a sinus leading to a cavity of comparatively small size, not reaching to the apex and not extending far forwards; and on April 2nd I removed portions of three ribs, 1½ in., 2½ in., and ¾ in. respectively, the longest piece being in the middle and the smallest above. The patient at this time had some albuminoid changes of the viscera, as shown by a large liver and some albumen in the urine, but his general condition was good. The result of this was a great diminution in the size of the cavity and falling in of the chest; but as there was clearly a cavity of some size left, Mr. Beck, under whose care the patient has passed, removed on Oct. 15th 1½ in. of the fifth, 2¼ in. of the sixth, 2¼ in. of the seventh, 1⅝ in. of the eighth, and 1½ in. of the ninth ribs, with the subjacent pleura. This has practically taken away the bony part of all the external wall of the cavity; and as increased falling in is rapidly occurring, it is probable that this will lead to complete closure of the cavity.

CASE 6.—Francis S——, aged twenty-three, was admitted into the Brompton Hospital in June, 1883, with empyema of two years' standing, which he was expectorating. The general condition was very bad, and the expectoration very profuse. On September 6th I opened the pleura in the right axilla, excising a portion of the rib. By November 15th he had been healed some time, but expectoration had recommenced a few days previously, so the wound was reopened. Healing was almost complete, when expectoration again set in; so on Feb. 28th, 1884, I excised three inches of the two ribs which formed the wall of the cavity. The patient greatly improved, but left the hospital with a sinus in June. Since this time he has come under the care of Mr. Cross of Clifton, who made a second opening further back, the result of which has been the closure of the cavity.

CASE 7.—Alfred D——, aged thirty-six, was admitted into Brompton Hospital on July 15th, 1885, with a very chronic empyema. There was an opening in the back leading to a straight sinus five or six inches long, passing upwards and backwards, but there was no regular cavity. A piece of rib about four inches long was removed from the chest wall over this sinus, which it is hoped will prove sufficient, and a large drainage-tube was inserted, but at present the sinus is not closed. [This patient was shown at the lecture.]

CICATRICIAL STRICTURE OF THE OESOPHAGUS,



TREATED BY GRADUAL AND AFTERWARDS BY FORCIBLE DILATATION.

BY SIR WILLIAM MAC CORMAC,
SURGEON TO ST. THOMAS'S HOSPITAL.

WILLIAM M——, aged twelve, was first admitted to St. Thomas's Hospital on Aug. 13th, 1884. Three-quarters of an hour before admission he had swallowed some strong liquor potassæ in mistake for vinegar. He was discharged on Aug. 28th. He then felt some soreness of the mouth and throat and slight trouble in swallowing. This passed off, and for a week subsequently he had no difficulty in taking food, but he then noticed a gradually increasing difficulty in swallowing, until his readmission on Sept. 28th. At this time he stated he had been totally unable to swallow for the preceding twenty-four hours, and this continued till the following afternoon (the 29th), when he was able to swallow a little cocoa and some soaked bread. He had been fast losing flesh, and presented marked retraction of the abdomen, although by no means emaciated. Nutrient enemata were ordered to be administered every six hours. The patient was then transferred from the medical to the surgical ward, as a case probably requiring gastrostomy.

On Sept. 29th I examined the œsophagus, and discovered a tight stricture, only admitting, after many trials and great difficulty, a No. 4 urethral bougie. The obstruction was six inches from the edge of the upper teeth. A second less marked constriction was felt lower down. The bougie was passed into the stomach, and the patient was somewhat benefited, being afterwards able to swallow milk more easily and without pain. Bougies were now passed regularly, and gradually increased in size until Oct. 6th, when a No. 11 bougie could be introduced. And now, by means of an olive-ended instrument, a third well-marked constriction, not appreciable before, was discovered near the cardiac orifice of the stomach. This period of treatment need not be dwelt upon in further detail. Urethral and afterwards small-sized œsophageal bougies were passed twice a week, the patient's power of swallowing improved, and he was able to take soft food, such as bread-and-butter and minced meat, without much trouble. In the four weeks ending Oct. 30th he gained ten pounds in weight. It was found, however, to be quite impracticable to get further than No. 11; the strictures refused to dilate beyond this point. It was therefore determined, all efforts by means of gradual dilatation appearing futile, to attempt to dilate the strictures forcibly.

On Oct. 31st the patient was partially anæsthetised, but

Instrument used for the forcible dilatation of the œsophagus.

he became so much cyanosed that the anæsthetic was discontinued. I nevertheless forcibly dilated the strictures by means of an instrument which had been made for me. It is represented in the accompanying woodcut. It consists of three parts: (1) A thin flexible whalebone guide, which is first passed into the stomach, shown in the woodcut in two portions, which can be screwed together; (2) a rather flexible metal stem to travel along this guide, and retained in connexion with it by short lengths of tube placed at intervals on one side, the lower end of the stem being hollowed out to contain a female screw; into this may be screwed in succession (3) a series of olive-shaped heads terminating at the upper extremity with a male screw; these are graduated in size, and perforated from base to apex to run over the guide. The instrument was used thus:—The guide having been first passed into the stomach, one of the olive-shaped heads, the diameter of a No. 17 bougie, was screwed to the end of the metallic stem, passed along the guide into the stomach, and moved two or three times up and down the œsophagus. The tube was thus at once forcibly dilated, and the several obstructions could be felt to yield in succession. The amount of force employed was not excessive, but greater far than one would have ventured upon in the absence of the conviction that the guide prevented all chance of a false passage being made. A few drops of blood were afterwards coughed up; there was also a little pain, which soon subsided; other-

Digitized by Google

wise no ill effects whatever were experienced. From Oct. 31st to Dec. 7th a bougie No. 16 on the urethral scale was passed every other day, and the patient's power of swallowing improved. On the last-mentioned day a No. 18 bougie could be passed through all three strictures, and No. 19 through the upper two. On Dec. 18th the patient was anæsthetised, and by means of the instrument above described the œsophagus was dilated to the size of a No. 26 urethral scale. A No. 24 olive-headed bougie was afterwards easily passed into the stomach. From this date bougies were passed almost daily. About the end of January I again used the dilator and forcibly stretched the tube with an olive seven lines in diameter. The operation was repeated on February 27th, when one eight lines in diameter was passed through to the stomach, another of nine lines in diameter passing only the first stricture. No. 26 olive-ended sound was then easily passed every second or third day through all three strictures. On April 14th the boy was again put under chloroform and the guide introduced, but owing to violent vomiting it could not be retained long enough for the dilator to be adequately used; but an olive nine lines in diameter was forced through the obstructions. An ordinary œsophageal bougie, tapering to the point and eight lines in diameter at its thickest part, could be easily passed. For a few weeks previous to the patient's discharge on June 2nd, 1885, the large bougie, nine lines in diameter was passed at intervals without difficulty. It was now considered that the strictures had been sufficiently dilated. There was never anything more serious after the use of the dilator than pain lasting for six or seven hours and a few drops of blood mixed with the secretions. The tendency to further contraction had by degrees diminished, and now seemed practically to have disappeared. He was allowed to go home, with directions to reappear at short intervals to have a bougie passed. When the boy left the hospital he had for some time been able to swallow any kind of ordinary food as well as before. He had no pain or trouble, and had become quite fat; he seemed, in short, well, and there was no evidence of any recurrence of contraction. On Sept. 28th, 1884, the boy's weight was 4 st. 1 lb.; on Oct. 30th, 4 st. 11½ lb.; and on Dec. 15th, 6st. 5½ lb.

Willie M——, left the hospital at the beginning of June, 1885, and a bougie was passed through the œsophagus at intervals of a fortnight or three weeks, until August 6th. Then an interval of nine weeks inadvertently ensued; but on my return from a holiday I nevertheless easily passed the full-sized bougie, nine lines in diameter, without feeling any sign of returning constriction. This was again passed on Oct. 8th, and again on Nov. 5th and 24th, on Dec. 30th, and on Jan. 4th, 1886. The condition of the tube at this time leaves nothing to be desired.

Remarks.—The important and satisfactory feature of the case is the condition of the gullet since the boy left the hospital. It has been examined periodically lately, at intervals of several weeks between each time, the last occasion being on January 4th, 1886, when the full-sized instrument, the largest ever introduced, nine lines in thickness and twenty-seven lines round, was passed readily from the mouth to the stomach without difficulty or any evidence of contraction in the tube. This instrument is probably as large as the normal œsophagus of a boy of this age will admit. The adult œsophagus, according to Dr. Mouton's measurements, obtained by filling the tube with plaster-of-Paris, is a little over half an inch at its narrow part, and three-quarters of an inch (nine lines in diameter), the size to which I dilated this boy's œsophagus, elsewhere. In all other respects the lad feels well, is stout and well-nourished, and able to swallow his food as well as he could before the accident took place. As now for a period of seven months no tendency to a recurrence of the contraction has shown itself, a cure may reasonably be counted upon.

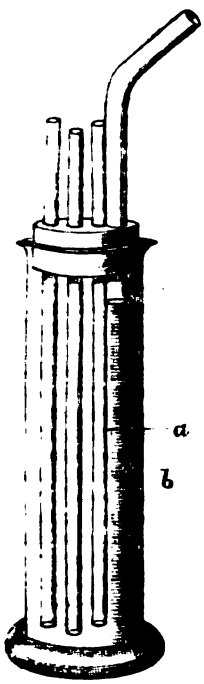
The operation of gastrostomy was at first contemplated in this case, as the contraction in the gullet was extreme; indeed the boy was sent to me with that object in view. Trendelenberg has performed this operation in a case of the kind, and the patient, also a boy, was alive and well years afterwards; but he was compelled to feed himself entirely through the artificial opening, the food being first masticated in the mouth and then spat down a tube into the stomach. How incomparably superior the condition of my patient is does not require to be insisted upon. I took care to perform the overstretching or forcible dilatation in several successive operations about four in all, so as to better avoid the risk of infiltration or extravasation into the cellular tissue of the neck, which might have been incurred by doing over-much at one time. So far as may be judged by the result of one case the method seems safe, and in this instance it has certainly proved successful. I should scarcely have performed these forcible dilatations had not the method of gradual dilatation completely failed to carry one further than the size of a No. 11 urethral bougie. I preferred this method to the use of the œsophagotome introduced into practice by Maisonneuve. Its employment has been attended with very serious risk of mediastinal or pleural abscess, or of possibly uncontrollable hæmorrhage. Of seventeen cases recorded, four of these patients died within fifteen days of the operation, and it is probable that unfavourable results followed in some of the other cases. After partial dilatation had been accomplished there was no pressing need for so serious a measure as gastrostomy at this stage of the malady; but by the means adopted the boy had been only very partially relieved, and the contraction would have been pretty sure to reappear as soon as he left the hospital. It was needful, therefore, to attempt to secure some more permanent benefit for him, and this appears to have been permanently realised by the method of forcible dilatation of the œsophagus.

ON A NEW METHOD OF INHALATION AND A NEW FORM OF APPARATUS.

BY ARTHUR HILL HASSALL, M.D. LOND.,
LATE SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL, CONSULTING PHYSICIAN TO AND FOUNDER OF THE NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.

IT is possible that the method of inhalation which I am about to describe may have been already employed in an imperfect manner; but, so far as I am aware, the principles on which it is based have not been described, and thus the method has not been reduced to a system.

The air, owing to the law of the diffusion of gases and vapours, contains a variable quantity of the vapour of water; the scale from the point at which the air is entirely free from moisture to that at which it becomes saturated with the vapour, and will therefore hold no more, has been divided into 100 parts or degrees, "0" representing perfectly dry air and "100" the point of saturation. The relative humidity of the air is determined mainly by the rainfall, temperature, and the pressure of the atmosphere. Bearing in mind the preceding particulars, it occurred to me that, if air more or less dry were passed through a medicated solution, it would take up an amount of that solution sufficient for medical purposes. In order to test whether this supposition was correct or not, I devised the following apparatus. This consisted of a glass cylinder, nine inches high and nearly two inches in diameter, closed at the top by an accurately fitting cork. In the cork were inserted four tubes; one of these, larger than the rest, pierced the cork and entered the cylinder for about three-quarters of an inch; the other three were much smaller and longer, reaching almost to the bottom of the cylinder. In this itself were placed 175 cubic centimetres, equal to 2700 grain measures of a mixture consisting of distilled water and 17½ grammes of pure crystallised carbolic acid. The three smaller tubes were used in preference to one large one, because by this arrangement the air passed into the solution in the form of a number of small instead (if only one tube had been used) of a few large bubbles. In the latter case the air would not have been brought into sufficient contact with the water, and such a commotion would have been created as to cause spirting of the liquid and the liability of its occasional entrance into the mouth. This occurrence is entirely avoided provided that the due proportions of the apparatus are observed and a sufficient space be left between the surface of the medicated liquid and the end of the tube which forms the mouth-piece. When this apparatus is in operation the air is drawn through the three small tubes; from the bottom of these it freely escapes, ascending through the liquid in bubbles, which burst on the surface, and the air thus charged with the medicament is inhaled by means of the tube placed in the mouth, as in the accompanying figure.



The earlier experiments about to be detailed were made

Digitized by Google

with the above-described simple apparatus; in other experiments the three small tubes were attached by means of indiarubber unions to a large tube filled with dried chloride of calcium, the object being of course to deprive the air of the moisture which it contained, and thereby to increase its power of absorbing the solution through which it was passed. Except when otherwise stated, the inhaler was charged with 175 cubic centimetres of a mixture of water and carbolic acid in the proportion of 10 grammes of the acid in 100 cubic centimetres of the mixture. The inhalation was continued for one hour, and the nares were kept closed.

Experiment 1.—Temperature of the air 58° F.; relative humidity 79°. The carbolic acid was dissolved in a mixture of glycerine and water. It was found at the end of an hour's inhalation that 3·5 cubic centimetres of the mixture (= 54·0 grain measures only) had disappeared; also, that the residual mixture possessed nearly the same strength as at first. The 3·5 cubic centimetres of the mixture therefore contained 5·4 grains of carbolic acid.

Experiment 2.—Temperature 58° F.; relative humidity 77°. In this case no glycerine was used, and the mixture in place of being clear was milky, owing to a part of the carbolic acid being suspended in it in the form of minute droplets, which under the microscope resembled those of milk. The loss in this case was the same as in the previous case, and the residual mixture was found to possess the same strength as at first.

Experiment 3.—Temperature 59° F.; relative humidity 60°. The nares in this case were not closed. Loss 6·0 cubic centimetres, containing 9·2 grains of carbolic acid.

Experiment 4.—Temperature of air 88° F.; relative humidity 81°. The air was passed through about half an ounce of chloride of calcium; the loss amounted to 7 cubic centimetres, and since the mixture after inhalation was found to possess precisely the same strength as before, the loss of carbolic acid amounted to 10·8 grains.

Experiment 5.—Temperature 57° F.; relative humidity 82·5°. In this experiment the carbolic acid was increased to 15 grammes in 100 cubic centimetres — that is, the mixture was made half as strong again and a larger quantity of chloride of calcium was used. The loss was 11·5 cubic centimetres, and since the residual mixture retained its original strength 26·6 grains of carbolic acid had disappeared.

Experiment 6.—Temperature 60° F.; relative humidity 55°; the air being consequently decidedly dry. In this case also 15 grammes of acid were contained in 100 cubic centimetres of the mixture. The air was passed as before through chloride of calcium, and the apparatus was placed in a jug of hot water, the temperature of the liquid in the apparatus rising at first to 70° F. The vapour which came over was very strong, especially at first, and the loss amounted to 12·5 cubic centimetres containing 28·9 grains of carbolic acid.

Experiment 7.—Temperature 57° F.; relative humidity 77°. The nares in this experiment were not closed. The mixture was of the same strength as in the first experiments, and the air was passed through chloride of calcium. The loss amounted to 8·0 cubic centimetres, representing, as confirmed by analysis, 12·3 grains of carbolic acid.

Experiment 8.—The conditions were precisely the same as in the previous case, only that the nares were kept closed. The loss was 7·25 cubic centimetres, representing 11·2 grains of carbolic acid. In both these experiments the foot of the glass cylinder was placed in a shallow dish of warm water, which raised the temperature of the mixture to a small extent only. These two experiments show that it makes little difference so far as the loss of carbolic acid is concerned, whether the nares are closed or allowed to remain open.

Experiment 9.—Temperature 57° F.; relative humidity 80°. The apparatus was placed in a jug containing hot water, which at the commencement of the inhalation had a temperature of 120°. The inhalation at first had to be carried on slowly and intermittently, as the air was so strongly charged with the acid as to cause the throat to become painful. At the end of half an hour it was found that 8·5 cubic centimetres of the mixture were vapourised, this being at the rate of 17 cubic centimetres in the hour, representing a loss of 26·2 grains of carbolic acid.

Experiment 10.—Temperature 49° F.; relative humidity 80°. The chloride of calcium was dispensed with, the nares were not closed, and the inhaler was placed in a jug of water which had a temperature of 120°. This heat caused the temperature of the carbolic acid solution to rise to 62° F. The air inspired contained so much carbolic acid that in a few minutes it caused the throat to become sore and painful. At the end of thirty minutes 8·5 cubic centimetres of the mixture had passed over, or 17·5 cubic centimetres, containing 27·0 grains, in an hour. This and the previous experiment show in a marked manner the effect of even a very moderate elevation of temperature in increasing the amount of watery vapour and of acid in the air inspired. The residual mixture was as strong after the inhalation as before. It is therefore evident that if the temperature of the medicated liquid be raised even a few degrees in the simple manner described, passing the air over chloride of calcium and closing the nares may both be dispensed with. It should be stated that the respiratory capacity of the person using this inhaler was fully one-third below the normal standard; had it been of the average capacity, the amounts of carbolic acid inhaled, as recorded in the above experiment, would have been considerably increased.

The results of the above experiments are highly satisfactory. They show, first, that if the air contain much moisture and the temperature of the liquid is low, the quantity of medicated liquid taken up by the air is comparatively small; secondly, that if the air be artificially dried, the amount is greatly increased; and, thirdly, they show that if the temperature of the solution be raised to even a very moderate extent, the quantity is still further augmented; indeed, the effect of warming the solution is so great that it is not necessary to dry the air by means of chloride of calcium at all, and the apparatus may be employed in its simplest form.

The apparatus used in the experiments I made myself. For the chloride of calcium tube I took the chimney of an ordinary petroleum lamp: this was closed below by a cork, perforated for the entrance of three small tubes, corresponding in size with those of the glass cylinder, the two sets being united by small pieces of indiarubber tubing. At the bottom of the long narrow part of the chimney a piece of muslin was placed to prevent the chloride of calcium blocking up the tubes; the chimney itself was filled, or nearly so, with the lime salt, which, when properly dried, may be used repeatedly.

It is manifest therefore, from the experiments detailed, that by means of the inhaler I have devised it is possible to introduce into the lungs a great variety of medicaments, and this to such an extent that the quantities would have to be carefully regulated in order to avoid any undesirable consequences. That the medicaments do really enter the lungs is unquestionable, because if the nostrils be closed, as they were in most of the experiments, respiration is almost entirely carried on by the air which has been made to pass through the medicated solution. The nostrils may be easily closed, either by means of the fingers or by a small clip, such as chemists use to close indiarubber tubes; but the medicated air may be made to enter the lungs freely enough, and of sufficient strength for all purposes, even when the nares are not closed. Of course a portion of the medicament carried over by the air becomes, in its passage towards the lungs, deposited on the mucous membrane of the throat and the other parts with which it may come into contact situated above the epiglottis. When 10 grammes of carbolic acid are made up with distilled water to 100 cubic centimetres, part of the acid remains undissolved if the water be of a somewhat low temperature; when the mixture is agitated, however, it becomes opaque and white, like milk, the undissolved portion of the acid being in the form of globules of various sizes. When the apparatus is in use, the milky condition of the liquid is maintained, and the globules freely

Digitized by Google

pass over in the carbolised air at each inspiration. When the temperature of the mixture is raised, the acid becomes dissolved and the mixture loses its milky character, regaining it again as it cools. This complete solution of the carbolic acid is readily effected by simply placing the glass cylinder in a jug of water at a temperature of about 120° F.

Certain modifications of the apparatus were experimented with. In one case a longer cylinder was employed, with, of course, longer tubes and a greater quantity of the mixture. In another the air was passed through two cylinders placed side by side, the idea being that in both cases the air would become charged to a larger extent with the carbolic acid; but the results were disappointing, and it was found that while the smaller apparatus requires but little exertion to work it, much greater force is required in the case of both the modifications referred to.

In using this apparatus the inspirations should be slow, deep, and effective, so as to cause full expansion of the lungs, whereby at length the power of inspiration is increased and strengthened, a result highly beneficial in many cases. The cylinder should be graduated in spaces of 10 cubic centimetres, so that the amount of the medicated solution inspired may be accurately measured. Once charged, the apparatus may be used several times in succession without being refilled, trouble thereby being avoided.

This inhaler is, I believe, one of the most effective which has hitherto been devised, and if the tubercle bacillus be the cause of consumption, and if it be possible to destroy this bacillus by means of medicaments, this apparatus is capable of conveying to the lungs the requisite amount of any medicament which possesses even a lower degree of volatility, such as do most of the remedies employed in affections of the lungs. For non-volatile substances the inhaler is of course not effective.

It having come to my knowledge that a difficulty has been experienced in procuring my oral and oro-nasal inhalers, I wish to be permitted to state that they may now be obtained of Messrs. Maw, Sons, and Thompson.

San Remo.

ON THE

REMOVAL OF DEEP-SEATED TUMOURS OF THE NECK.

BY ARTHUR E. BARKER, F.R.C.S.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL, AND TEACHER OF PRACTICAL SURGERY AT UNIVERSITY COLLEGE.

WITHIN the last year or so a good many cases have presented themselves to me which have offered the opportunity of testing an opinion I have long held—namely, that under the new *régime* of antiseptic surgery deep-seated tumours of the neck may be dealt with far more freely than is generally supposed, in spite of the advance we have already made. In other words, I believe the conclusion justified that tumours of the neck which a few years ago would have been held to be incurable from their deep situation and relations may now be removed without extreme difficulty, and with the best results. This is but another way of saying that when we use proper antiseptic precautions the old nightmare of deep-seated cellulitis in the neck need have no terrors for us, that with anæsthetics and deliberate dissection bleeding and shock are not prominent dangers, and that we are only limited now in the extent to which we shall attempt the removal of these tumours by anatomical considerations. Even the latter, I think, will be shown by some of the following cases to be more elastic than many are inclined to believe. Four cases are selected as being the last and most serious, and as having all been treated in the same way, both during and after operation.[1] They offer, besides, a basis for the above reasoning, some details which appear worth notice. In the first place, all the tumours lay beneath the sterno-mastoid muscle, and on this ground alone would a few years ago have been considered as outside the range of operation. In Case 1, so deep seated was the growth that the scalenus anticus muscle and internal jugular vein were implicated in it, and had to be cut away with it above and below after careful double ligature of the vein. Again, it is noticeable that there were no symptoms either during or after operation that any of the nerves of the neck had been injured, even in the last case, in which the phrenic and other important trunks were in relation to the tumour. Nor was there any evidence that ligature of one or more of the larger veins of the neck gave rise to trouble of any kind. Further, we find these wounds healing from bottom to surface by first intention as simply as the least important incision in other parts. Again, it is shown that the omission of the carbolic spray in these particular cases for special reasons did not leave any gap in the otherwise complete antiseptic precautions, and that the substitution of salicylic wool for carbolised gauze admitted of more decided, more elastic, and more evenly applied pressure being applied on and about the wound than would have been borne with the inelastic gauze. This last point is, I venture to think, of no little importance. Finally, it has not escaped my notice that in most of these cases there has been some transient rise of temperature within the first twenty-four hours. This I have closely watched, but as it has been unaccompanied by any signs of septic absorption, such as headache, malaise, sickness, anorexia, pain, throbbing, or tenderness about the wound, or any constitutional disturbance, I have felt little or no uneasiness in any case, and have not felt it necessary to change the dressings at once to inspect the field of operation. I have put the pyrexia down in each case where present to tension from serum in the wound, the firm bandaging contributing perhaps a little. At all events, the course of convalescence and the sequel showed that no pus was formed, and that nothing was left to be desired as regards the results immediate and remote.

CASE 1.—Mr. E. A. T——, aged thirty-five, was placed under my care by the kindness of my colleague, Mr. Heath, in February, 1885. He was a gentleman of strong and healthy appearance, with a good personal and family history. In January, 1883, he first noticed a small lump about the size of a pea on the right side of the neck, about three inches from the middle line. This increased gradually until four months before I first saw him, when it had attained about the size of an egg. At Christmas, 1884, it began to increase very rapidly, and soon became as large as the patient's fist. No pain was experienced nor difficulty in swallowing. About a year before there was loss of voice for a week or ten days, but at that time there was no change in the tumour. On examination on February 24th, I found a conical tumour on the right side of the neck with the apex below almost resting on the clavicle, and the base all but touching the lower border of the jaw above. Its posterior border was overlapped by the sterno-mastoid muscle, under which it ran for a considerable distance. In front the most prominent part reached the middle line of the thyroid cartilage; but above and below this point its outline fell away. The skin over the tumour was healthy and freely movable on it, and the growth itself was freely movable on the subjacent parts. It did not move up and down with the larynx. The vessels of the neck were not pressed upon appreciably. The swelling was cystic above, but apparently solid below and behind, and was accompanied by two distinctly enlarged glands lying in the posterior triangle of the neck immediately above the clavicle. Neither the pharynx nor mouth were encroached upon in any way. On aspirating the part, I drew off three ounces of dark-brown serous fluid, followed by about a drachm of pure blood; but before the patient had left my consulting-room the sac had filled up again, presumably with blood. In the aspirated liquid were several flocculent masses, which showed under the microscope a delicate papillomatous structure. From this examination of the growth I came to the conclusion that it was a cystic sarcoma, but was uncertain as to the exact point of origin. In consultation with Mr. Erichsen, who endorsed this diagnosis, it was determined to remove it. This I did on March 12th, 1885, as follows. Adopting all the most careful antiseptic precautions except the spray, I made an incision over the anterior border of the sterno-mastoid from an inch below the lobe of the right ear just to the sterno-clavicular articulation. With a little dissection the tumour was laid bare. I now made a second incision from the termination of the first towards the symphysis of the jaw for about two inches. The flap so formed was turned forwards and the dissection was carried

[1] I am indebted to Mr. F. Penrose for the abstracts of the cases on which these notes are based.

Digitized by Google

deeper. Here some small vessels spouted and were secured, as well as some small veins. The descendens noni nerve was found adherent to the tumour, and was dissected off. Deeper down the internal jugular vein was found to be involved in the growth, and seeing this I ligatured it below the mass with a double ligature. I then traced the distal part in its surroundings up to its bifurcation into two trunks, presumably the facial communicating branch with the temporal and the continuation of the internal jugular itself, and these being tied, the lower part, equalling about an inch and a half, was left in the wall of the tumour between the two ligatures. At this stage of the dissection the thin cyst burst and gave exit to dark-brown fluid, some clots, and some shreds of solid growth. This collapse of the cyst made the deeper part of the dissection now easier than would otherwise have been the case; although, had I not been careful to prevent it in the earlier part of the operation, I should have been completely baffled in attempting to separate its thin walls from the surrounding structures. The tumour was now found adherent to the scalenus anticus muscle, the middle portion of which had to be removed with the growth, which came away easily on the division of the muscle above and below. Leaving a carbolised sponge in the large resulting wound, the glands in the posterior triangle were removed by an incision just above the clavicle. Through the incision I passed a drainage-tube under the sterno-mastoid into the larger cavity, and then brought the skin wounds together with silk sutures. Before doing this the whole space was well dried out with sponges and dusted with iodoform. I now carefully adjusted pads of salicylic wool over the seat of operation, so as to bring all the wounded surfaces firmly into apposition, and over these pads I placed a very large quantity of wool, in order to be able to exert considerable pressure by bandages while allowing a certain amount of play of the parts for respiration and deglutition. The tumour removed consisted of a solid mass about the size of a Tangerine orange, from which a smooth-walled cyst projected of about the size of an ordinary orange; into this a soft, friable, villous mass projected from the solid portion. The glands were evenly enlarged, and homogeneous on section. After the operation the patient spent a very good night, and suffered no pain. The wound was dressed for the first time on the sixth day, and was found united almost completely by first intention. There was a little serous oozing from the drainage-tubes, but no pus. Both tubes were shortened, and the part was dressed as before. These dressings were again changed on the tenth day, and a trace of turbid fluid, hardly pus, was found about the drainage opening. The latter was washed, and all was dressed as previously. The next day, as the whole wound had united soundly except where the tubes lay, they were removed. On the thirteenth day the drainage openings were closed, and the patient was up on the fourteenth day, quite well, and went home on April 1st, feeling no inconvenience about the seat of operation. The temperature had risen on the evening of operation to 100·6°, but was subsequently usually below 100°. On the eighth day it rose, for some reason, to 102°, but fell almost immediately, remaining nearly normal for the rest of the patient's sojourn in bed. No symptoms accompanied these rises, and the wound showed nothing to account for them. In short, convalescence was uninterrupted by anything giving the slightest cause for anxiety. During the operation only a mere trace of blood was lost, and this more than anything accounts for the fact that even the deepest part of this very deep dissection in the neck gave very little more trouble than the most superficial. The fact that the scalenus anticus was divided close to its origin and not far from its insertion, and removed to this extent, is a sufficient indication of the depth of this dissection and of the important structures encroached upon by the tumour, as also the fact that the internal jugular was doubly ligatured and severed designedly. Moreover, it should not be forgotten that the sterno-mastoid muscle was not divided, and that the whole field of operation lay practically beneath it, and yet the walls of the large resulting cavity came together under pressure and healed by first intention, without any bagging of fluid, as might possibly have taken place had not firm pressure been kept up upon its walls throughout the healing process. It is interesting to speculate as to what became of the phrenic nerve. The dislocation of parts by the tumour in its growth prevents any certain conclusion being formed upon this point. This much may be said, that during the dissecting off of one [illegible] nerve from the anterior and inner aspect of [illegible]

the growth respiration was noticed to become of a sobbing character, becoming quite normal again when this was completed and before the close of the operation. One considerable nerve is also noted to have been divided of necessity in the middle of the operation, but I do not believe this could have been the phrenic from its situation. No symptoms referable either to division of nerves or excision of the internal jugular vein were observed after operation, although closely watched for. This gentleman was examined for me at his home in the autumn by a medical man who was present at the operation. He found him in perfect health, with no evidence of recurrence, and with all his sensations normal. I have since seen him, ten months after operation, and he says he feels as well as ever he did in his life. There is no trace of recurrence anywhere. The growth, which is a very peculiar one, about the exact nature of which there might be some difference of opinion, will be described shortly at the Pathological Society. I still regard it as a cystic sarcoma, starting probably in an accessory thyroid gland.

CASE 2.—H. W——, aged fifteen, was admitted into University College Hospital, under my care, on March 23rd, 1885, on account of a large swelling on the left side of the neck. He was a weakly lad, and had had several of the diseases of childhood, the last being measles in March, 1883. In the family history lumps in the neck appear in two members. In 1882 the patient first noticed lumps in the neck on the left side and under the jaw; these became hard, but not painful. During the attack of measles in March, 1883, they are said to have completely disappeared, returning again during convalescence, and then growing more rapidly than before. They soon extended behind the ear and down the neck, though almost painless and giving rise to no symptoms of pressure. On admission, March 23rd, the swelling was mainly below the body of the jaw on the left side, but overlapped the bone considerably. It extended forwards to the middle line downwards to within two inches of the clavicle, and backwards under the sterno-mastoid to within two inches of the middle line. The tumour was felt to consist of four large masses, freely movable on the subjacent parts and more or less on one another. Below the main swelling there was a chain of smaller glands running beneath the clavicle. There were no other enlargements of superficial glands to be felt either in the axillæ, groins, or on the other side of the neck, and the spleen was of normal size. The red corpuscles of the blood were 40 per cent. below the normal standard; the ratio of white was 4 to 400 red. On March 27th, I first made an incision from below the tip of the left ear to the left sterno-clavicular articulation directly over the tumour. The external jugular vein was then divided between two catgut ligatures. The tumour was now carefully enucleated by blunt dissection underneath the muscle, until the four great lobes shelled out of their bed, remaining still attached by the chain of smaller glands extending downwards along the great vessels of the neck, which were freely exposed. With very great care these glands were also freed from their surroundings with blunt instruments, the closeness to the great vessels demanding extreme caution. The carotid, only covered by its sheath, was exposed for a considerable distance, and the internal jugular vein from its junction with the subclavian upwards for an inch and a half was seen distended with blood. In spite of the proximity of many vessels, very little blood was lost throughout the whole operation. The glands were found to be less and less enlarged as the dissection was carried downwards, and I believe none were left behind in an abnormal state. When the whole mass had been removed, an opening was made into the resulting cavity behind the sterno-mastoid and a little above the clavicle for drainage. In this a tube was placed, as also in the lower angle of the main incision. The latter was then sewn up (a sponge being left in to the last moment), dusted with iodoform, and dressed with carefully adjusted pads of salicylic wool, so as to bring the deeper internal surfaces of the cavity into contact. Over these pads a large mass of the same wool was firmly bandaged to give strong elastic pressure. Three hours after operation the temperature was 98·2°, from which it rose steadily for six hours and a half, until at 1.30 it had reached 102·2°, then falling as steadily again to 99°; the next night it again rose to 101·8°, and remained the next day between 100° and 101·4°. The patient seemed very comfortable, slept well, and had no pain or other subjective symptoms accompanying the rise of temperature. On the 30th the wound was dressed for

Digitized by Google

the first time, and a free discharge of odourless serum was found in the wool round the tube. Otherwise the seat of operation was all that could be desired: it was soft, and not even tender. The tube was shortened and the dressings applied as before. The temperature came down after this first dressing, and remained almost normal throughout. The drainage-tube was again shortened on the 31st, and on April 4th was removed, the stitches being taken out on the 6th. After this there is nothing to note except that union appears to have been almost entirely by first intention even in the deepest part of the wound, there being no trace of pus from beginning to end of the process. The patient was out of bed on the thirteenth day, and the drainage openings were definitively closed on the nineteenth day. The mass of glands removed weighed 15½ oz., and showed no trace of inflammatory action or degeneration on section, being simply generally hypertrophied. I heard later from the lad's father that he remained quite well.

CASE 3.—W. G——, aged twenty-three, clerk, was admitted into University College Hospital on June 19th, 1885. He was a delicate-looking man, subject always to night-sweats. There was a family history of phthisis. Six weeks before admission the patient first noticed a swelling in the lower part of the neck on the left side, just above the clavicle. This rapidly increased, but there was no pain. On admission it was found to be a lobulated glandular mass, 3½ in. by 2 in., freely movable on the subjacent structures and under the skin. No other enlarged glands were to be felt in the body. Heart and lung sounds were normal. From their rapid growth and hardness it was considered possible that these nodules might consist of a new growth, and it was therefore determined to remove them. On June 24th, 1885, I first made an incision for three inches parallel to the anterior border of the trapezius down to the clavicle. Through this I was able to enucleate the entire mass of glands, including a prolongation of the chain downwards and inwards under the clavicle, which could not be detected until the body of the tumour was dislodged. This blunt dissection was very deep, and the subclavian vein was exposed for a considerable distance. Nevertheless, the glands came away entire and cleanly, and with little or no loss of blood, owing to the use of blunt instruments for dissection—i.e., director or curved elevator. The wound was dusted with iodoform after it had been well dried out, and was stitched up, a sponge being left in until the last moment. It was drained at the lower angle and then dressed with well-adjusted pads of salicylic wool as in the last case, and firmly bandaged. The arm was also fixed to the side with bandages, so as to keep the clavicle and deeper surfaces of the operation cavity at rest. The glands removed were much enlarged individually, and each had a large caseous focus; those running under the clavicle were least affected. The night after operation the patient had no pain and felt well, but did not sleep until he had some morphia on account of the patient in the next bed disturbing him. The next morning, though he still felt well, his temperature was 103·2°, pulse 100, respiration 20, and his face flushed. From this time until the evening of the day following, the temperature steadily fell, and was normal throughout afterwards. There was a complete absence of any other symptoms pointing to constitutional disturbance. For this reason I did not touch the dressings until the third day, and then only to loosen the bandages a little, leaving everything else undisturbed. The first dressing was on the seventh day, when the wound was found healed by first intention except at the drainage opening. On the fourteenth day the patient was well and up, only one point where the tube was removed being unhealed; this was quite closed on July 10th, and the next day the patient was discharged. I have seen him since, in December, 1885, six months after the operation. He then looked and felt very well, and had gained flesh and colour. There was no trace of enlargement of glands near the seat of operation, but on the opposite side of the neck some could be felt, but he said they were getting smaller.

CASE 4.—Mr. A——, aged twenty-five, came to me from Wales on June 20th last on account of a fistulous track leading from the edge of the sterno-mastoid inwards to a hard mass of caseating glands lying over the bifurcation of the great vessels of the neck. This sinus had existed for some years, and had given much trouble, especially when it closed and the matter was retained. On examination, I came to the conclusion that nothing but complete enucleation of the mass of diseased glands would give complete security against the persistence of the fistula for an indefinite time. As the patient was very anxious to be freed, and was of delicate constitution and likely to suffer from the continuous discharge and to run considerable risk of generalisation of the tubercular infection from the glands, I agreed to do what might otherwise be thought an unnecessarily severe operation—namely, to dissect down all round the glands and remove them *en bloc*. This I did in the way described in the last case through an incision running along the anterior border of the sterno-mastoid for about three inches. In this dissection the great vessels were exposed considerably, and planes under the sterno-mastoid opened freely. The glands were difficult to isolate on account of the chronic suppuration, but were removed without breaking into the inflamed area. The wound was dressed and treated as in the last two cases, and healed by first intention and without a bad symptom.

Experience in these and several other similar cases has certainly dissipated many of the apprehensions inherited from a former period, and encourages me personally to extend the sphere of operative procedure in the deeper parts of the neck very considerably.

Harley-street, W.

ACUTE PARENCHYMATOUS MYOCARDITIS.

BY SAMUEL WEST, M.D., F.R.C.P.,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK, AND TO THE ROYAL FREE HOSPITAL; MEDICAL TUTOR AND MEDICAL REGISTRAR TO ST. BARTHOLOMEW'S HOSPITAL.

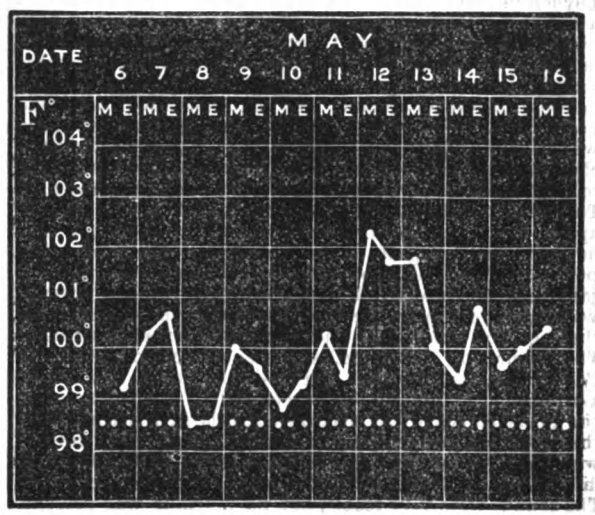
THE classifications of myocarditis are somewhat confusing. Accepting the general term of "carditis" as indicating inflammatory conditions of the heart generally, the terms "endocarditis" and "pericarditis" speak for themselves; but myocarditis, or inflammation of the solid substance or mass of the heart, is less clear; and of the classifications suggested I prefer greatly that of Virchow, who applies to myocarditis the same epithets used in distinguishing the various forms of nephritis, hepatitis, &c., and divides the whole group into the parenchymatous and interstitial varieties, each of which may occur in the acute or chronic form, and affect the whole or only part of the organ. Chronic interstitial myocarditis is what we usually speak of as fibroid disease of the heart. The small abscesses found in the heart in some forms of blood-poisoning are instances of one form of acute interstitial myocarditis. The term "parenchymatous" is open to the same objections when applied to the heart as to the kidney, and the same difficulty arises in drawing the line between inflammatory and degenerative changes; but it is a term which is in common every-day use, and which represents certain broad facts, and it may be used with advantage in reference to the heart in the same general sense.

The common classification of myocarditis into primary and secondary forms is etiological, the group of primary or idiopathic myocarditis being reserved for those cases in which no cause for the affection can be found. We do not speak any longer of idiopathic or primary nephritis, and it would be well if we ceased to apply this term to the heart. 1. Acute parenchymatous myocarditis may exist alone, and we may place with Virchow in this group all those acute changes observed in the myocardium in such severe fevers as typhus, small-pox, &c., as well as those rare cases in which the muscular substance alone is attacked in the course of rheumatic fever. To this group most of the cases to be described belong. 2. It may occur coincidently with some other acute affection of the heart—viz., pericarditis or endocarditis,—as it probably did in Case 8. 3. Lastly, it may follow some antecedent affection of the heart—old pericarditis, old endocarditis, or even chronic interstitial myocarditis.

Where acute parenchymatous inflammation passes into the chronic form and ceases to be inflammation and becomes degeneration is as difficult and perhaps as impossible to determine in the heart as in the kidney. The classification, like that of nephritis, is purely pathological. It is not perfect, but, on the whole, it is, I think, the most clear and

Digitized by Google

satisfactory. The classification of myocarditis will, therefore, stand as in the following table:—



- Myocarditis
  - parenchymatosa (*a*) partialis (*b*) universalis
    - acuta
      1. No other part of heart attacked.
      2. In coincidence with endocarditis or pericarditis.
      3. In sequence to endocarditis, pericarditis, or even chronic interstitial myocarditis.
    - chronica — ? chronic parenchymatous degeneration.
  - interstitialis
    - acuta — suppurative. non-suppurative.
    - chronica — fibroid disease of heart.

The cases which follow all belong, so far as post-mortem evidence is forthcoming, to the group of parenchymatous myocarditis. In only one was old interstitial change present as well.

CASE I. *Myocarditis; no other lesion in the heart; liver cirrhotic.*—John L——, aged twenty-seven, was admitted into the Royal Free Hospital on May 6th, 1884. He had been a heavy drinker for many years, but had been in good health until about three years ago, when he was confined to bed for some weeks with rheumatism and weakness of the legs, and for this was an in-patient in the hospital under Dr. Baxter. He was an in-patient a second time a year ago under myself, suffering from general *muscular tremors* and from the effects of drink. These tremors were referred at that time to drink, aggravated perhaps by the effects of lead-poisoning, from which he was also suffering. After a few weeks these symptoms entirely disappeared. Lately the patient had been out of work and living badly. He had been much exposed to wet weather, and had doubtless been drinking. Three weeks before admission the weakness and tremulousness of the legs returned. He had at times a great feeling of *coldness* followed by perspirations, suffered much from *nausea*, and occasionally vomited. A week before admission he was much distressed with *pain* across the upper part of the abdomen (chiefly in the epigastric region), and shortly afterwards he became slightly *jaundiced*. The patient was a stout, flabby, unhealthy-looking man, with a pasty, slightly jaundiced, and dusky complexion, and puffy face. The whole body was affected with a peculiar tremulousness, increased by movement. This was most striking on the chest, where it was constant, and not in any way timed with respiration. The tongue was similarly tremulous and covered with yellow fur. Pulse 120, small and weak; respiration 32, shallow and somewhat laboured; temperature 99·5°. The heart's apex was in the nipple line, and the cardiac dulness increased upwards and to the left, but it could not be made out beyond the right edge of the sternum, probably on account of the emphysema present. Over the whole præcordial region a soft systolic murmur was present, which was heard also for some distance into the axilla. The heart sounds were audible, but weak and distant, and the pulmonary second accentuated. Slight rhonchus was heard over the whole of the lungs. The abdomen was greatly distended, and the superficial veins large, chiefly over the upper part. The liver dulness commenced at the upper border of the seventh rib, but its lower edge could be felt on a level with the umbilicus. Its surface appeared smooth, but resistant. There was slight ascites, and slight œdema of feet and legs. The patient was troubled with frequent cough and fairly copious watery expectoration. The urine (sp. gr. 1015) contained bile and a little albumen. What was most striking in the patient's appearance was the dusky and slightly jaundiced colour, the general tremors, and his great prostration.—May 10th: Pulse 100, and stronger; heart's sounds more distinct; urine of higher specific gravity (1022), still containing bile, but free from albumen.—12th: The patient had been wandering for the last two nights, and was extremely restless, requiring constant watching to keep him in bed. Temperature 102°.—13th: Patient weaker, constantly muttering to himself, and very restless; complained of nausea and dyspnœa. To-day were noticed for the first time twitchings of the face muscles, which recurred frequently, and during the evening and night (May 14th) he had three epileptiform fits, the arms being most affected. The fits were followed by deep sleep. The urine passed was small in quantity, sp. gr. 1028, but free from albumen.—15th: There had been no more fits, but the patient was more drowsy and feeble and the dyspnœa was much greater. Tongue dry, with sordes in mouth. Urine passed in bed. Pulse 130, very feeble; temperature 100°. Attacks of twitching in face were frequent, lasting about half a minute at a time.—16th: The dyspnœa was greater, and at midday the patient suddenly sat up in bed, became livid, struggled for breath, and died in about an hour's time, the final change being sudden. (See Chart.)

The post-mortem disclosed old adhesive pleurisy with emphysema and extreme congestion of lungs. The larynx was healthy. The pericardium was healthy, and contained but a very small amount of clear serous fluid. The heart was universally dilated; the valves healthy, but the muscular substance yellow and mottled with fatty change. It was easily torn and teased up, and showed under the microscope considerable fatty and granular disintegration of fibres. The coronary arteries were normal and there was no cause for the fatty change found in the heart. The abdomen contained a little fluid. The liver weighed 89 oz., and was markedly granular and firm. The spleen weighed 8 oz., and the kidneys 6 oz. each. These organs were much congested, but otherwise not abnormal. The brain and spinal cord were carefully examined, and no change discovered.

In brief, a young man, aged twenty-seven, addicted to drink, from the effects of which he had seriously suffered on many occasions, after more heavy indulgence than usual became weak and tremulous and suffered from attacks of cold perspirations and faintness, with epigastric pain, dyspnœa, and slight jaundice. On admission the patient was dusky and slightly jaundiced, with marked dyspnœa and

constant, though not severe, epigastric pain, a very rapid and feeble pulse, and considerable pulmonary congestion. The cardiac dulness was enlarged, the sounds rapid and very feeble, and accompanied by blowing systolic murmurs. Gradual increase took place in all the symptoms, but especially in the dyspnœa, and the patient died suddenly and somewhat unexpectedly.

All the clinical phenomena pointed to the heart as the source of trouble; and the post-mortem examination confirmed this view, for the only other organ diseased was the liver, while the heart itself was in a condition of extreme degeneration, though the pericardium, endocardium, and valves were unaffected.

Accepting the view taken during life, confirmed as it was by the necropsy, as correct—viz., that the case was one of acute muscular degeneration of the heart,—there remain for decision two questions: (1) The name by which it would be best described, and (2) the cause to which it may be attributed. It is impossible in most cases to draw the line sharply between inflammation and acute fatty degeneration, for, as we see in acute nephritis, fatty change follows so quickly upon inflammation as to form almost part of the process. We may, therefore, without refining too much, I think fairly apply the term myocarditis to the case, and, as the change was general and of short duration, we may add the terms diffuse and acute, and describe the disease as myocarditis acuta diffusa. The only ground for hesitation in thus naming the disease would be the stated rarity of the affection,

Digitized by Google

except when associated with and secondary to other changes in the heart, such as pericarditis or endocarditis, the absence of which in this case was proved by necropsy. The next question to be considered is the cause of the disease in the present instance. No local cause, in the first place, existed in the heart. Of the general causes to which myocarditis is often referred, there was no history or distinct evidence of rheumatic fever, and all the common forms of blood-poisoning were absent, and there was no evidence of any ordinary fever, such as typhoid, &c., or even pneumonia, nor of pyæmia or other septic fever. The only other diseased organ in the body was the liver, and although the disease of the heart may be connected with the disease of the liver in the sense that if the liver had been healthy the myocarditis might not have occurred, still the causal relation between the two affections is somewhat remote and impossible of proof, and we may be justified, therefore, in describing the present case as one of primary rather than secondary myocarditis. Every disease must have a cause, and I should be rather inclined to refer the heart affection in this patient to the toxic effect of the recent drinking bout, than to the chronic and probably not very advanced change in the liver. My own observation leads me to believe with Prof. Köster and Rühle that acute myocarditis is not by any means so rare a disease as is commonly stated, nor that it is always of short duration or necessarily fatal.

CASE 2. *Myocarditis; cirrhotic liver.*—This case, almost the exact counterpart of the preceding, is published by Leyden in the *Charité Annalen* for 1883. The patient was a male, aged thirty-four, who was admitted into the hospital on December 26th and died on January 16th (twenty-one days)—a drunken "ne'er-do-well," who had lived on his wits for the last six years, and had had syphilis two years before his present illness. He had been ailing for some years; he said he had been in his usual health until three weeks before admission; he then suffered from pain in the chest and oppression in breathing, and had been confined to bed. Twelve days previously his testicles had swollen. The present complaints were of great weakness and want of appetite, pains in the chest, and shortness of breath, so that he could hardly speak. The patient was of moderate size, poorly nourished, but not emaciated. The skin was slightly jaundiced and the trunk and back of the thighs covered with numerous petechiæ, and there was slight œdema of the legs and scrotum. The temperature was not raised. The respiration was rapid, shallow, and costo-abdominal. Pulse rapid, 128, irregular, and of small volume. There was a diffuse feeble impulse felt over the whole cardiac area, but the apex could only just be localised in the fifth space outside the nipple line, and could not be seen. The cardiac dulness was increased slightly upwards and towards the left, but did not extend beyond the usual position towards the right. The sounds were very feeble, but no murmur was present. The urine (sp. gr. 1007) contained no albumen and no bile; there was slight ascites. The diagnosis was made of dilatation of the left ventricle, without valve or kidney mischief, probably of syphilitic origin.

In the course of the next few days the patient improved, the petechiæ disappeared, the temperature continued normal, and the pulse was reduced to 80, though occasionally it rose to 113. The digitalis was stopped. On Jan. 2nd the pulse was again quicker (120) and more feeble; there was more jaundice, the hepatic region was somewhat tender, and the patient not so well. On the 8th there was slight wandering. Temperature 98·4°; pulse 90; specific gravity of urine 1030, no albumen; the patient weaker. The digitalis was again administered, and quickly reduced the pulse. On the 13th the pulse fell so low as 48, and on the 14th to 40; it was at the same time irregular and weak, so that the digitalis was stopped. On the 15th the patient complained of headache, and on the 16th he became suddenly faint and died in a few minutes.

The post-mortem examination showed slight œdema of the feet, legs, and scrotum, with a little ascites, but no fluid in the pericardium or pleural cavities. The pericardium was adherent over a small part of the right auricle, and thickened a little in patches over the front of the right ventricle. Elsewhere it was smooth, and there was no evidence of recent pericarditis anywhere. The valves and endocardium were healthy, but the muscular substance was spotted here and there with yellowish patches. The lungs were congested, but otherwise normal; the liver hob-nailed. On microscopical examination the muscular substance of the heart was found to be fatty, the change being most marked on the inner surface. Here and there were several small patches of old fibroid induration, and in two places the arteries corresponding with them were occluded by endo-arteritic change.

Professor Leydon discusses the question whether the dilatation to which the symptoms and death were due is to be referred to the old syphilitic change, or to more intense myocarditis in the earlier part of the present illness, or whether both the dilatation and fatty change are to be referred to the cachexia and consequent general malnutrition. He leaves these questions unanswered, but suggests that all these factors had their share in producing the condition. The dilatation he diagnosed from the position of the apex beat with the alteration in the cardiac dulness and the weak heart from the feeble heart sounds and small pulse. He draws attention to the fact (1) that the patient's complaint did not point very directly to the heart, and that he suffered from discomforts rather than actual pain in the cardiac region, and from oppression of breathing rather than dyspnœa; (2) that the pulse was so small and irregular, and varied much in form and frequency, and was especially subject to the influence of digitalis; (3) to the dropsy without reduction in the amount of urine; and (4) to the sudden syncope which ended in death.

It would be difficult to find two cases of an obscure and not very common disease which resemble one another more closely in all respects. In one important point only do they differ—namely, in the temperature; for in my case the temperature was slightly raised, and in Professor Leyden's was normal. Both patients were young men, and complained of similar symptoms; both had jaundice, slight ascites, and œdema, both had the evidence of weak dilated heart, both died suddenly, and in both were found a fatty heart and cirrhotic liver; in both the diagnosis was made during life, and confirmed after death.

Although of the six cases which follow three died, in two only of these was the diagnosis established by post-mortem examination, and I have therefore thought it well to take the two cases just described first, as establishing a firm pathological basis upon which the other cases may stand. In connexion with them I may place next another completed case which I quote from a paper written by me in the St. Bartholomew's Hospital reports for 1878, for the use of which I was indebted to the kindness of Dr. Bristowe.

(To be continued.)

A NOTE ON MALARIAL ICTERUS AND HÆMOGLOBINURIA.

BY C. H. EYLES, L.R.C.P. & S.EDIN.,
ASSISTANT-SURGEON, GOLD COAST COLONY.

AFANASSIEW,[1] in endeavouring to account for the variable and disproportionate icterus accompanying hæmoglobinuria, finds, among other things, that, for the production of hæmoglobinuria, solution of the hæmoglobin into the blood-spasm is a necessary and invariable antecedent, though the latter condition may exist without necessarily producing the former. When icterus and hæmoglobinuria co-existed, the animals experimented on "bore it badly," the urine responded to Gmelin's test, and the kidney showed casts of bile-pigment and hæmoglobin. So far as the liver was concerned, in the cases where hæmoglobinuria alone was produced, histological changes in that organ were observed; while, when icterus likewise was present, these changes were more or less pronounced, and the bile in the gall-bladder and bile-ducts was found to be of increased consistence. The form of icterus which he proposes as explaining the phenomena is one he terms "hæmo-hepatogenous" icterus—i.e., it is a hepatogenous icterus determined by pre-existing hæmic changes, in so far that these bring about an increased formation of biliary constituents which are subsequently absorbed. Applying these facts to clinical observations, we find that while this "hæmo-hepatogenous" icterus may account wholly or partially for the discolouration of the skin in some cases, it cannot be said to cover another series of cases in which,

[1] Virchow's Archiv, vol. xcviii., p. 469, *et seq.*

Digitized by Google

together with icterus, there is no response to Gmelin's test in the urine, as in malarial fevers, &c.

On the west coast of Africa, where malarial fevers, from the mildest to the most malignant, are met with, one form of remittent occurs in which hæmoglobinuria is so prominent a symptom that it furnishes the popular name "Blackwater fever." In these cases there is acute hepatic tenderness, with enlargement, accompanied by hypercholia, as evidenced by the stools and the vomit, which, when other than ingesta, is a tenacious, viscid, golden-yellow fluid when the stomach is very irritable, and a copious green liquid when the stomach permits of accumulation; there is more or less profound icterus, and a tendency to suppression of urine, which in three fatal cases was icteric as well as hæmoglobinous. In these three cases the clinical phenomena—i.e., the icteric and hæmoglobinous urine, hepatic complication, and character of the vomit—lend countenance to the adoption of "hæmo-hepatogenous" icterus as an explanation of the discolouration of the skin. But what of the other cases in which the urine was non-icteric? It might fairly be urged that the hepatic symptoms were the result of the over-action to which the liver was urged by the condition of hæmoglobinæmia; and the appearance of profound icterus, without corresponding response by the urine to Gmelin's test, shows that, though the conditions necessary for the production of hæmo-hepatogenous icterus may exist, the discolouration of the skin may not be due to it in the first instance, though in some cases it might be partially accounted for thus.

Are we, then, to adhere still to a "hæmatogenous" icterus, meaning by that term a jaundice produced by chemical changes occurring in the blood itself, by which its colouring matter is converted into material capable of imparting a yellow appearance to the skin and conjunctivæ? As a reply to this, we find that "the formation of pigment in blood which is actually circulating is not carried beyond the first stage (the breaking up of red corpuscles) within the vessels; the completion of the process is effected outside the vessels."[2] Hepatogenous icterus being, then, inadmissible on the clinical evidence, pigmentary material not being formed in the blood as such, can it be that, the first stage of the process—the liberation of the hæmoglobin—being already accomplished in cases of hæmoglobinuria, the pigment formation is completed outside the vessels—i.e., in the tissues themselves? in other words, that the icterus arises in the same manner as the discolourations following extravasation of blood, the difference being that in the former case it is general and rapid, owing to the transudation of serum holding hæmoglobin in solution, while in the latter it is limited and tardy in appearance, owing to the fact that the extravasations are limited, and the corpuscles have first to be destroyed before the connective tissue corpuscles can act on the hæmoglobin? This seems probable. "It may even be" says Quincke,[3] "that under certain circumstances icteric pigment may not only be formed in tissues other than the liver, but may be formed so extensively and under such conditions that general icteric discolouration results; the formation of this pigment in the connective tissue, after extravasations, for example, permits us to speak of an *icterus icterus* as possible; this would be a special form of an hepatogenous icterus; another special form would be the hæmatogenous—if it were known.

If this be accepted as the explanation of icterus accompanying hæmoglobinuria, and the malarial fevers in which this latter occurs, can it account for the icterus of malarial fevers, at least, in general? that is, are we to assume that because icterus occurs in these fevers, it is preceded by hæmoglobinuria? Recent research, I believe, spares us the trouble of assuming. Remarking on the observations of Laveran and Richard on the microbe of paludism, recently confirmed and extended by Marchiafava and Celli,[4] THE LANCET[5] says: "The organism has a special habitat, the red corpuscle of the blood, in which it develops, and which it leaves when it has arrived at a perfect stage of development. During the attack of fever many globules are seen which possess a small, perfectly round spot, but they have otherwise the normal appearance, and possess [illegible] elasticity. In other corpuscles the evolution of the parasite is further advanced, the clear spot is enlarged and is encircled by small black granules, while around it the hæmoglobin, recognisable by its greenish-yellow tint, forms a ring, which becomes narrower and narrower as the parasite increases in size. Ultimately the substance of the corpuscle is reduced to a narrow decolourised zone, from which the hæmoglobin has disappeared"; and this disappearance of the hæmoglobin from the corpuscle and its consequent passage into the plasma supplies the requirement of hæmoglobinæmia necessary for the production of general inogenous icterus. Another matter is not uninteresting in this connexion—viz., that urobilin occurs in the urine in fevers generally,[6] and in cases where there has been extravasation of blood.[7] In continuation of the remarks above quoted, THE LANCET says: "Many other phenomena of the disease—the remarkable anæmia, the action of quinine, and the persistence of the infection—are all perfectly explained by these facts"; and among these phenomena, icterus, hæmoglobinuria, and congestion of the liver and spleen, seem to claim a place as being produced by the hæmoglobinæmia resulting from the presence of the parasite.

It might be asked if we are to consider the presence of hæmoglobinuria a sure and certain sign of the intensity of malarial poisoning. Thus, it might be said, when the poisoning is but mild, as in intermittent fever, the amount of hæmoglobin set free is such as can be dealt with by the liver, spleen, and bone-marrow; when more severe the additional hæmoglobin is employed in the production of inogenous icterus, as in remittents; the appearance of hæmoglobin in the urine, indicating a still further amount set free, shows intensity of the poisoning; while the addition of hæmo-hepatogenous icterus indicates a very high degree of intensity. Here, however, we are checked in arriving at any such conclusions, for the urine may be hæmoglobinous even in cases of mild remittents without any icterus, as I have seen, or it may be so in intermittents; and in Europe an apyrexial manifestation of malaria is met with in paroxysmal hæmoglobinuria, in which there might be no icterus whatever; or it may be present out of all proportion to the hæmoglobinuria. Why this should be we know not; and even in experimental pathology we find that under conditions apparently the same, in the one instance hæmoglobinuria alone is produced, while in another the urine is first icteric and subsequently hæmoglobinous.[8] To say that this is due to the varying capacity for work of the organs and tissues in different individuals is to offer no explanation, for yet the question would remain to be answered, Whence the varying capacity? That there is some difference even the old woman who prefers her family doctor because "he knows her constitution" is aware: but the family doctor deludes himself when he believes he explains the matter by veiling his ignorance behind the six-syllabled word "idiosyncrasy."

Nulla autem est alia pro certo noscendi via, nisi quampluirmas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. MARY'S HOSPITAL.

A CASE OF CONTRACTED GRANULAR KIDNEY; DEATH; NECROPSY.

(Under the care of Dr. SIEVEKING.)

THE following case is a very instructive one. A female, aged thirty, had a convulsive seizure without apparently any previous symptom of importance, and died within three weeks afterwards from uræmia, the result of pronounced renal disease. Contracted granular kidney is not common at this age, and the disease was far advanced when the patient came under treatment. The urine was greatly diminished in quantity, there was slight general anasarca, considerable

Digitized by Google

arterial tension, and much cardiac hypertrophy. Headache, nausea, vomiting, convulsive seizures, and other symptoms of uræmia rapidly came on, and the patient died comatose a fortnight after admission. The kidneys were extensively diseased, and together weighed only an ounce and a half. The notes of the case have been furnished by Mr. Geo. Spear.

Lydia P——, aged thirty, an anæmic; weakly-looking woman, was admitted to this hospital on Nov. 10th, 1884. The patient had a fit ten days previously; while talking to her mother and sister she suddenly fell, striking her head against the fender. She remained unconscious for "several hours," and during the fit had bitten her tongue. She has been in a very weak state ever since, becoming faint and giddy, and trembling on the least exertion. Her previous history showed that she had been subject to cough and cold every winter for several years, and generally had to get medical advice for it. She suffers from rheumatic pains in the joints, but has never had rheumatic fever. The patient has noticed that her face and the lower extremities have swollen occasionally for some time past. Does not think she has passed more urine than usual lately. She has frequently had pain under the left breast, with shortness of breath on walking quickly or going up-stairs. Patient gave birth to a child seven years ago. The catamenial flow has been regular until four months ago—absent since then. The family history showed that patient's father died of "chest disease and rheumatism" at the age of fifty. The mother was living, but in delicate health; she suffers from some chest affection and is nearly blind. There have been eight brothers and sisters. One sister died of consumption at the age of eleven years; the rest are living. One brother suffers from rheumatic gout, and another was troubled with fits during childhood. Some relatives of her father have died of consumption.

On admission, there was slight puffiness of the face with patches of ecchymosis, and a nearly healed scar over the outer angle of the left orbit. Skin warm, slightly moist; tongue coated with white slime, and a dark streak down the centre; temperature normal. Chest fairly well arched; impaired resonance over both fronts; respiratory murmur fair. At the back of the thorax slight dulness, with increased vocal resonance at both bases and at lower angle of left scapula. Cardiac dulness greatly extended. The heart's impulse was very forcible at the lower part of the fifth space; a systolic thrill was felt at the apex; there was a loud mitral systolic murmur at the apex propagated towards the axilla; an aortic systolic murmur was heard at the base, and a little above and below in the sternal line. Liver full size; dulness begins at the fifth rib. Spleen enlarged. Urine very pale; sp. gr. 1011; neutral reaction; albumen present, equal to one-tenth. The patient was ordered five-grain doses of citrate of iron and quinine in an ounce of peppermint-water three times daily, and an ounce and a half of compound decoction of aloes every other morning.

Nov. 13th.—Patient has had a sharp pain under the left breast during the night. The aortic and mitral systolic murmurs are louder and rougher; there is also a pulmonary murmur, persistent on increasing pulmonary tension. Pulse 90, hard, cordy, incompressible; temperature 97°; some nausea; urine pale, sp. gr. 1013, faintly acid, slightly albuminous.

15th.—Face slightly puffed. Patient was sick yesterday, and complains still of nausea and almost constant headache. Feels giddy at times. Pulse 96, regular; temperature 96·2°; last evening normal. A blister ordered to be applied to back of neck.

17th.—Patient complains of pain over the region of the kidneys. Face more puffed to-day. Pulse 104, hard, cordy. Both murmurs very marked; second sound reduplicated. Patient was slightly sick this morning. Ordered thirty grains of compound jalap powder every morning.

18th.—Patient had a fit last night and again early this morning; each attack lasted from four to five minutes. There was no cry. The fit began with clonic spasms, affecting both arms and legs and the muscles of the face and body. In the first attack the patient bit her tongue. The bowels being constipated, a simple enema was administered; later a three-ounce dose of black draught was given, which caused four loose stools. An injection of pilocarpine (one-tenth of a grain) was given hypodermically; this caused free but not excessive perspiration for about an hour. In the evening a vapour bath was given. The pulmonary and mitral murmurs are more marked. About eighteen ounces of faintly acid urine passed in twenty-four hours (bowels relaxed four times); sp. gr. 1013; one-tenth albumen. Nausea continues. Tongue coated. To take twenty minims of spirit of nitrous ether and ten minims of tincture of digitalis, in one ounce of water, three times a day.

19th.—Patient has had a good night, but complains of headache this morning. Tongue moist at the edges, covered with white slime, and having a dry brown streak down the centre. Pulse 96, hard, cordy, regular. Temperature 97·3°; last evening 99·1°.

20th.—Patient had four fits last night between 6.30 and 12. After the last attack she was partly unconscious for three-quarters of an hour, the hands twitching convulsively. She was unable to articulate; the left eye was directed inwards. A dose of bromide and chloral mixture was given, but she vomited it almost directly; a second dose at 4 A.M. was retained. The injection of pilocarpine was administered daily and the vapour baths were continued, but only moderate action of the skin was induced. Bowels open three times yesterday. The aortic and mitral systolic murmurs continue about the same. The heart's impulse is in the sixth space, forcible and heaving in character, but does not convey the impression of the same vigour as when patient was admitted. The face is much puffed; the right eyelids discoloured and erysipelatous. Pulse 96, regular, incompressible. Urine very pale; sp. gr. 1011; one-fourth albumen; deposits granular and epithelial casts. There is pulsation in the jugular veins and a loud venous hum, both stopped by making pressure below.

21st.—Patient had two fits last night, both lasting longer than the previous ones. The convulsive movements began in an attack on the right side of the face, then went to the right arm, then to the left arm and leg, and finally back to the right side again. After these attacks patient remains unconscious for half an hour or longer. Urine is generally passed during the fits; during the last fit both urine and fæces were voided. Patient is unable to answer questions to-day, and at times is in quite a frenzied condition for a moment or two. There is increased fulness and pulsation in the external jugulars. The heart could not be examined. Pulse 102, hard, cordy. Bowels open five times. Temperature 96·4°; last evening 99·4°. There has been slight epistaxis upon two occasions. Patient remained in a comatose condition the greater part of the day; she stares vacantly at anyone who goes near, and if she makes any answer to questions, it is always, "I don't know." Strong coffee was ordered three times a day. Four leeches to be applied behind the ears.

22nd.—Still unconscious, but there has been no return of the fits. The tip of the tongue, the teeth, and lips are covered with sordes. She refuses everything brought to her, so that only one cup of the strong coffee could be given. Pulse 104, regular, softer. Temperature 97·2°; last evening, 96·4°. Some urine was voided in the bed this morning; none passed during the night. A nutrient enema, consisting of half an ounce of brandy, an ounce and a half of beef jelly, and half an ounce of strong coffee, to be given every four hours.

24th.—Patient has not recovered consciousness. Little or nothing has been swallowed; the nutrient enemata have been retained. Respiration is deep, the intercostals and scaleni acting visibly at each inspiration. The bowels have been opened after two enemata of castor oil. A little urine has been passed in the bed. A hot pack was used last night and there seemed to be a momentary return of consciousness. The pilocarpine has now little or no action upon the skin. Pulse 100, full, jerky; temperature 99°; last evening 98°. Patient is much emaciated.

25th.—Patient is evidently sinking. Pulse 100, regular; temperature 99°. The nutrient enemata are generally retained; no liquid or food given by the mouth is swallowed. Fæces and urine are passed involuntarily. Conjunctiva sensitive. A hot pack was used last night, but caused no sweating. The respirations gradually became deeper, slower, and catchy, and the patient died at 1.20 P.M.

A post-mortem examination was made twenty-five hours after death. Rigor mortis was well marked; body much emaciated. The heart was hypertrophied, particularly the left ventricle; substance pale; aortic valves slightly thickened. Congestion and œdema of both lungs, especially the lower lobe of the right. The kidneys were extremely small: weight of left, one ounce; right, half an ounce.

Digitized by Google

Substance red and very granular; the cortical portion almost gone; only about one-sixteenth of an inch in thickness. A little fat was deposited from degeneration. Liver congested. Brain substance normal; slight effusion in the cerebral ventricles. A section of the kidney examined microscopically showed the organ to be so fibrosed as to be almost unrecognisable; every grade of fibroid degeneration was seen, from the crowd of indifferent cells between the tubules, to the masses of dense, almost homogeneous, fibrous tissue. The vessels were enormously thickened, and their nuclei increased. The glomeruli were much altered: the best of them were much over-nucleated; the worst were simply homogeneous fibroid masses. The capsules were much thickened. Considerable congestion of the organ was evident, apparently from the supervention of an attack of acute inflammation at the end of chronic nephritis. Not a single normal tube was to be seen; some were lined by degenerated cells, others by embryonic cells; some were reduced to fibrous bands, while others, again, were mere chains of cysts.

KASHMIR MISSION HOSPITAL.

ABSCESS OF KIDNEY COMMUNICATING WITH BOWEL; OPERATION; NECROPSY; REMARKS.

(Under the care of Mr. A. NEVE.)

THE following may well be classed among the cases of difficult diagnosis lately published by Dr. Fenwick. It is one which a more careful examination might have helped to elucidate. But in Kashmir the endeavour to obtain reliable accounts from the patients or intelligent notes from any hospital assistant is nearly hopeless.

A man, aged about forty, was admitted on Oct. 6th, 1884. He was spare, with a careworn expression, complaining of constipation for twelve days and of a painful lump in the left side. It was diagnosed as obstruction of the descending colon, and treatment by enemata was ordered. One or two thin motions followed, but the swelling remained with increasing fever and loss of appetite, but no vomiting. Mr. Neve's attention was not called to him till the fourth day after admission. He then found a considerable swelling of the left abdomen, between the ribs and the spine of the ilium. Fluctuation was perceptible, but the tumour was partly tympanitic. It was not very tender to the touch, and there was some gurgling on pressure. The puzzling point was the connexion between the swelling and the severe constipation. Another enema was ordered, which, however, was fruitless. Next day (Oct. 11th) a large enema was given, the body being inverted. The fluid seemed slowly to percolate through the whole length of the large intestine. Evidently the tumour was separate from the bowel. It was aspirated, and some very offensive fæcal fluid escaped, but the needle was blocked by small sloughy fragments. The enema returned, bringing away a large quantity of fæces.

Operation.—A few hours later, under the spray, an incision was carefully made into the tumour. A large quantity of most offensive liquid, of brownish colour and fæcal smell, escaped: also some flocculent matter and sloughs, one piece, six inches long, being a fragment of the intestinal mucous membrane. The finger entered a large cavity, crossed by numerous soft rotten bands. It appeared shut off from the rest of the abdominal cavity by firm adhesions. Above it entered a round movable aperture like an anus. In the position of the kidney was an ill-defined soft pulpy mass. The wound was well washed out, and a large drainage-tube applied, over which a sawdust pad was fixed. At the close of the operation the true nature of the case was still doubtful.

Next day (Oct. 12th) the temperature had fallen from 103° to 99°. There had been one or two motions. Urine normal in appearance. Pain slight. Pulse very weak. Wound dressed and washed out.

13th.—He was much weaker. About midday he had a rigor and became pulseless and insensible. Sixteen ounces of saline fluid were injected into a vein, with some marked improvement for a few hours. At night he died.

Necropsy.—Lungs much congested. In the right pleura there were twelve ounces of serous fluid. Liver congested and fatty in texture. Spleen enlarged. In the right kidney pelvis was a small encysted stone (weight 2 dr.). The descending colon was found to be much displaced towards the middle line, and to pass through a mass of inflammatory adhesions which formed the inner wall of the abscess cavity, with which the colon communicated by a small aperture. This cavity extended from the diaphragm to the iliac fossa. It was lined with a greenish gangrenous material. In the floor of it, amidst much sloughy material, were the remains of the kidney, the anterior wall of the pelvis being absent, revealing large cavities in the substance. The psoas muscle contained several ounces of pus.

Remarks by Mr. NEVE.—Throughout this case my diagnosis was in error. I had considered the possibility of hydronephrosis &c., but all the symptoms pointed towards the bowel. There was prolonged constipation; much thickening around the colon; a tympanitic tumour containing gas and fæcal fluid; also sloughs. I diagnosed a fæcal abscess, connected in some way with obstruction of the bowels, some portion of the wall of which had, I thought, sloughed, but had been repaired by adhesions. By the light of the post-mortem and the stone in the right kidney, I believe the starting-point to have been a hydronephrosis, due to blocking of the ureter; this was followed by rupture of the wall, perinephritis, communication with bowel, fæcal contamination and decomposition, obstruction, &c.; making a most puzzling combination of signs. If the man had come earlier he would probably have recovered. Immediate benefit followed the treatment, which was perhaps the best that could have been adopted, but it came too late.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Mortality in the Medical Profession.—Tapetum Lucidum.

AN ordinary meeting of this Society took place on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. The papers were both of peculiar interest, and the meeting was prolonged for half an hour.

Dr. WILLIAM OGLE, the successor of Dr. William Farr as Superintendent of the Statistical Department at the Registrar-General's Office, read a paper on Mortality in the Medical Profession. The paper, of which the following is a detailed abstract, has not only special interest for the medical profession, but is also, from a statistical point of view, a valuable contribution to statistics of class mortality, a subject upon which our information is at present mainly dependent upon figures derived from facts deficient in number and often not beyond all suspicion of inaccuracy. The basis of facts on which Dr. Ogle's conclusions are based is wide enough to inspire confidence, and the source of his information is above suspicion. At the last census in 1881 the number of "physicians, surgeons, and general practitioners" enumerated in England and Wales was 15,091, and after the census was over the causes of the deaths of all males aged fifteen years and upwards in England and Wales during the three years 1880, 1881, and 1882 were abstracted from the National Death Register, in combination with the occupations of the deceased persons. The result of this process, as regards the mortality of medical men, was to show that their mean annual death-rate in those three years was 7·40 per 1000 between twenty and twenty-five years of age, 11·57 between twenty-five and forty-five, 28·03 between forty-five and sixty-five, and 102·85 per 1000 at sixty-five years and upwards. Among all medical men aged upwards of twenty years, the mean annual death-rate was 25·53 per 1000. The first question suggested by these figures is whether the death-rate is high or low, and this inquiry naturally divides itself into two other questions. In the first place, is this death-rate of medical men in the three years 1880-1-2 higher than that of medical men in former times? and secondly, is it high compared with the death-rates of men engaged in other occupations? For an answer to the first of these questions, Dr. Ogle refers to the calculations of his predecessor, Dr. Farr, based upon similar investigations in 1860-1 and 1871, from which it appears that the annual death-rate of medical men aged upwards

Digitized by Google

of twenty years was 23·60 in 1860-1, and rose to 24·98 in 1871, whereas it had further increased to 25·49 in 1880-1-2. These death-rates are all corrected for differences in the age-distribution of the profession at the successive periods, each of the rates being calculated on 1000 medical men having the same age-distribution as existed in 1881. The fact of the progressive increase in the mortality of the medical profession between 1861 and 1881 is therefore established. It is to be noted, however, that the increase in 1880-1-2, compared with the earlier periods, is practically confined to the later periods of life, while among medical men under forty-five years of age the rates had generally declined. The increase at all ages is due to the increase at the later ages being greater than the decline at the earlier ages. Dr. Ogle points out that these features of the mortality statistics, the decrease at the earlier and the increase at the later ages, are not peculiar to the medical profession, being common to most of the other professions and industries. These features are discussed at some length in Dr. Ogle's report to the Registrar-General on the mortality of the country in the decennium 1871-80. Contrary, however, to the case of the medical profession, "the lives saved at the earlier ages were in excess of the lives lost at the later ages" in most other occupations, and among the male population generally, independently of occupation. In part explanation of this increase of mortality among the male population of England at the later ages coincidently with a decrease of mortality in the earlier stages of life, it is urged that it is due to the "increased wear and tear of adult life, brought about by the growth of population, and by the keener struggle and competition which this growth necessarily brings with it." In the second place, it is suggested that a certain "number of comparatively weak lives, which in pre-sanitary times would have perished in infancy or childhood, have been preserved, and by their survival may have diminished the average vitality of the population at more advanced ages." Dr. Ogle then passes on to compare the mortality of medical men in 1880-1-2 with that of men engaged in other occupations, and gives a table showing the annual death-rates in those three years in a number of different professions and trades. Each of the rates is calculated for 1000 males, aged upwards of twenty years, with the same age-distribution as the medical profession. The death-rate of medical men is shown to be far in excess of that in other professions. Thus the death-rate is 15·93 in the clerical profession, 20·23 in the legal profession, and 19·90 in the scholastic profession, while in the medical profession it is, as has been stated, 25·53. The rate in the medical profession is not only higher than in any of the other learned professions, but also compares unfavourably with the rates in most other trades and industries, and is indeed "only exceeded by the rates in certain trades and occupations that are notoriously unhealthy." Having established beyond doubt the fact of the marked excess in the mortality of the medical profession, Dr. Ogle proceeds to consider what are the causes to which this excess is attributed, or rather what are the diseases under which it occurs. This information has been derived from copies of the entries in the Death Register relating to the deaths of 3865 medical men during the years 1873-82, forwarded to the General Medical Council in accordance with legislative enactment for the due correction of the Medical Register. Dr. Ogle's information based upon these facts is, as he asserts, unique in character. No similar information unfortunately exists for any other profession or industry. The number of deaths dealt with is fairly large. The deaths were spread over a period of ten years, and they occurred in all parts of the country; they may therefore with full confidence be accepted as a fair sample of the causes of death of medical men. The 25,535 deaths estimated to occur annually among 1,000,000 medical men are therefore assumed to be caused by the various diseases in the proportion shown by the classification of the causes of the 3865 deaths. The result of this distribution gives the annual death-rate per 1,000,000 medical men from each cause of death dealt with. A table is appended giving, side by side with these death-rates from the several causes among medical men, the rates from the same causes among all males in England and Wales, irrespectively of occupation, and duly corrected for differences of age-distribution. The result of this comparison is to show that, with very few exceptions, the mortality of medical men is higher from every disease or group of diseases than is the mortality of males generally. Under some of the headings the "medical mortality is twice, or thrice, or even more times greater than the average." The table gives the comparison for twenty-six headings, in only five of which is the medical death-rate lower than that for all males. It is pointed out, moreover, that only three of these five headings, under which the advantage is on the side of medical men, are of any numerical importance—namely, phthisis, diseases of the respiratory organs, and accident; and, as regards accident, the rate among medical men is really excessive if compared with that among other males, if a small number of highly dangerous occupations, such as mining, quarrying, and sea-fishing, be included. There remain, therefore, only two headings under which the medical mortality is markedly below the general average—namely, diseases of the respiratory organs and phthisis; the medical mortality from diseases of the respiratory organs was 27 per cent., and that of phthisis no less than 45 per cent. below the average for all males. These causes of death are most fatal among those classes of the population liable to destitution, and it is therefore possible that mortality statistics for other sections of the middle or professional classes would show death-rates from phthisis and diseases of the respiratory organs as low as those prevailing among the medical profession. One of the most interesting features in the comparison between the rates of mortality from various diseases in the medical profession and among all males is the contrast presented by small-pox and other zymotic diseases. The annual death-rate from small-pox among all males aged upwards of twenty years is 73 per 1,000,000, whereas in the medical profession it is only 13, showing that although the profession is of course very much more exposed to the risk of infection than any other class of male adults, their mortality is scarcely more than a sixth of the average. The only possible explanation of the fact appears to be the great probability that medical men are more generally and better vaccinated than the rest of the male population. In the case, however, of other infectious diseases "against which no similar prophylactic remedy is known, the comparison gives a very different result. The mortality of medical men from scarlet fever, typhus, diphtheria, enteric fever, malarial fever, and erysipelas is very largely in excess of the average. The excess of mortality from remittent and intermittent fever is attributed to the large proportion of the profession who have served abroad in the army or the navy, or who have practised in India or the colonies. The death-rate from scarlet fever in the medical profession is 59 against an average of 16; from diphtheria, 59 against 14; from enteric fever, 311 against 238; and from erysipelas, 172 against 136. The marked excess in the death-rate from liver diseases, which is 1744 in the medical profession against an average of 744, may, it is suggested, be partly due to the same cause to which is attributed the greater fatality of malarial diseases. It is pointed out, however, that the death-rate from gout is 291 against an average of 78; from diseases of the bladder and prostate, 634 against 287; from other diseases of the urinary system, 1520 against 665; from diabetes, 284 against 108; and from alcoholism, 178 against 130. With regard to these figures Dr. Ogle says: "It becomes difficult to resist the conclusion that the main part of the enormous mortality from hepatic diseases is due, despite the indignant protest of Professor Casper to the contrary, to the neglect by medical men, as a body, of those wise rules of diet which they lay down for the guidance of their patients." The excess of mortality from liver diseases in the medical profession is 134 per cent., and from urinary diseases 128 per cent.; while, on the other hand, the excess from diseases of the organs of circulation is only 41 per cent., and from diseases of the nervous system only 7 per cent. above the rate among the general population. The excess in the death-rates from diabetes and malignant diseases is attributed to the probability that the diseases to which medical men succumb are more correctly diagnosed and more carefully stated in the death certificates. With regard to the death-rate among medical men from accident, it appears certain that if this could be compared with the rate from the same causes among men engaged in other professions and belonging to the middle-class, the accident-rate in the medical profession would show a considerable excess, whereas it is below the average for all males, including those engaged in mining, quarrying, and sea-fishing. The death-rate from suicide is 363 per 1,000,000 among medical men, against an average of 238 for all males; and it is further pointed out that

Digitized by Google

the tendency to suicide is increasing in the medical profession, whereas no corresponding increase is shown in the figures for the general male population. In order to facilitate a comparison between the death-rates from suicide in the three principal professions—legal, clerical, and medical—the annual rates were specially calculated for the six years 1878-83; they are given as 128 for the clerical, 354 for the legal, and 464 for the medical professions. The numbers upon which these rates were calculated are comparatively small, but it is urged that the rates, at any rate, conclusively prove that suicide is far more common among the medical than among either of the two other professions. The suicide figures show that medical men, as regards the methods of self-destruction, show a notably preferential choice for poison. In 26 of the 55 cases of suicide among the 3865 deaths of medical men, taken as a sample of the causes of death in the profession, or 47 per cent., death was effected by poison, and it is further noticed that in no less than 14 of these cases of poison prussic acid was the selected agent. In conclusion, it is remarked that the statistics given in the paper prove the fallacy of the ancient belief that "the life of a medical man is, as a rule, longer and healthier than that of other men"; but while the "results of this pitiless test of statistical inquiry are utterly incompatible with that ancient and optimistic view, it is at any rate not unsatisfactory to note that they offer on the whole a much less gloomy view of the condition of the profession than the figures given by former inquirers, such as Prof. Casper and Dr. Escherich."

—Dr. GEORGE JOHNSON said the comparatively few numbers of deaths from small-pox in medical men was a favourable item. Deaths from other infectious diseases were numerous, and this was what one might have expected from the great exposure of medical men to such affections. The reason why the mortality was so high from enteric fever was a question of much importance, and could not be explained on the assumption that the houses of medical men were not in as good a sanitary condition as the generality of people. He thought that the attendance on the poor at their own homes, where medical men had to enter the worst dwellings in London, was the chief way in which they contracted this disease, which would, he thought, be found to fall chiefly on that class of medical men who attended the poor. The great exposure to cold of many country practitioners would probably be one reason for the frequency of urinary diseases, and not alcoholism.—Mr. NOEL HUMPHREYS ventured to offer some remarks on the purely statistical part of the paper. It had been most conclusively shown that the death-rate was much in excess of males generally and of other professions, and also that it was increasing. With regard to the causes of death, he considered that Dr. Ogle's paper made a comparison between medical men and the working classes, which composed the majority of the male population, and this fact prevented the comparison having full weight. The comparison should be made with other members of the middle class. As to phthisis, it had been shown that the mortality was below the general average, but the general male population were more exposed to the weather and to the hardships of poverty than, as a rule, medical men were. He considered that this immunity was due to a class difference, and not peculiar to medical men, but enjoyed by other members of the upper and middle classes. The extent of respiratory diseases bore a direct proportion to the degree of poverty. The greater frequency of liver and digestive diseases was probably to be attributed to the excessive eating and drinking, as well as to want of exercise, and this was probably also a class difference. He regarded Dr. Ogle's paper as a most valuable contribution, especially to class mortality statistics. In the existence of the Medical Register he considered that there were unusual opportunities for constructing a real life-table of medical men.—Mr. NEWBATT, the well-known actuary, criticised Dr. Ogle's paper from the statistical point of view, and doubted whether its results completely disposed of the difficulty. The numbers, he pointed out, were comparatively small, and therefore liable to errors; 15,000 was not a large number to work with, and when these became distributed the results would be still less reliable in each of the sections. They would be required to be received with some little caution. A very slight difference in the mode of grouping would cause a remarkable difference in results; an incorrectness in the statement of the age, even, would make a difference when small numbers were dealt with; these peculiarities were well recognised by students of vital statistics. He was rather startled to hear that the death-rate in the medical profession was excessive, for he believed that most statisticians had arrived at a different conclusion. Dr. Guy, forty years ago, read a series of papers on Longevity in the Learned Professions, and showed that there was little difference between the professions, though even then there was a slight difference in favour of medical men and of the clergy as compared with lawyers. True, these statistics were based on unscientific methods, but as such they were of equal value with Caspar's; yet, as a matter of comparison between the professions themselves, they were of some value. Dr. Ogle's statistics were scientific and original, and could not be compared with data from other professions, because such data did not at present exist.—Dr. C. H. F. ROUTH joined in the discussion.—Dr. J. G. GLOVER doubted whether thirteen deaths from small-pox was a credit to the profession; he considered that there ought to be none, seeing that nurses and attendants on cases of small-pox could protect themselves absolutely from the disease by effective revaccination. Dr. Ogle's statistics showed that the annual death-rate of the profession in England and Wales was about 386 a year, and even doubling this number so as to include Scotland and Ireland, we then had 772 as the waste of the profession; this number, he pointed out, was greatly in contrast with the 1600 given as the annual loss to the profession by Dr. Lyon Playfair. If Dr. Ogle's statistics included deaths of unqualified and unregistered practitioners, that might prove a source of error. The night-work, the irregularity of habits, the wear and tear of medical life, and the want of care that medical men took of their own health, would probably explain partly the excessive mortality.—Dr. C. T. WILLIAMS was surprised that respiratory diseases should prove so comparatively rarely fatal to medical men, seeing the amount of exposure to weather that they experienced. He argued that, as medical men were able to ward off death from respiratory diseases, there was hope that they could do something to reduce their mortality from hepatic and digestive diseases. Could Dr. Ogle give any information as to the relative value of a medical man's life according as he was resident in town or country? The public ought to know of the excessive mortality of their medical attendants, and would probably sympathise with the hardships of their lives; but insurance offices, on learning the information, might be inclined to "rate up" the lives of medical men.—Dr. DOUGLAS POWELL said that Dr. Guy's results were appended in a foot-note to Dr. Ogle's paper.—Dr. OGLE, in reply, said that no doubt the comparison between medical men and the general male population was a faulty one in some respects, but it was the only comparison available. We had at present no means of obtaining the mortality of other learned professions. In reply to Mr. Newbatt, he admitted that he had dealt with a small population, but that could not be helped. He said, however, that the number dealt with for three years would really mean three times 15,000. Still, additional credit might be given to his results, since they coincided with the figures of the census of 1861 and 1871, and so had the additional support of similar results. The only authorities that he had quoted, Caspar and Escherich, gave an even higher mortality than he had obtained. The number of unregistered practitioners included in his statistics would certainly be small, even if there were any, and he did not think that this item could lead to any flaw of appreciable dimensions. He did not enter into the reasons for the deaths from different causes, but simply stated them, and he had no information which would enable him to give an answer to the question put by Dr. Williams.

Mr. HENRY LEE read a paper on the Tapetum Lucidum. The object of the paper was to show that the rays of light from different points which pass through the pupil and impinge upon the tapetum lucidum are reflected again in a concentrated form, as from a concave mirror. In the ox and in the sheep the greater part of the rays so reflected are brought to an ill-defined focus near the mouth. In the dog and the cat the reflected rays are more nearly parallel and are projected forward and downward in a direction nearly parallel with the median plane. In relation to the orbit in the ox and the sheep, the tapetum is principally on the outer side. In the dog and the cat it is principally on the inner side. In relation to the optic nerve, the tapetum in the ox occupies almost exclusively the upper and outer part of the back of the eyeball. In the cat and the dog it is situated above the entrance of the optic nerve, equally to its inner and outer side. In the horse the tapetum

Digitized by Google

is very well developed. It extends fully two inches in its transverse diameter when spread out. The vertical diameter is larger on the outer than on the inner side. The reflected rays from the former are directed downward and inward, as in the ox. The rays from the latter are directed more downward and forward, as in the dog and cat. Fish have no tapetum. Birds, supposed to have the longest and keenest vision, have no tapetum. The conclusions arrived at were: That by reflected and concentrated light the tapetum has an illuminating power which enables animals which possess it to see better in the dim twilight than those which have it not; that this power can be utilised only at comparatively short distances; and that the rays of light reflected from the surface of the tapetum are concentrated and directed in accordance with the habits and instincts respectively of different classes of animals.—Mr. W. H. JESSOP said that the tapetum lucidum is situate between the chorio-capillaris and the ground substance of the choroid, so as to be pierced by bloodvessels. There were two kinds of tapeta: the tapetum fibrosum, as seen in the horse and ruminants; and the tapetum cellulosum, as met with in carnivora and seals. Fishes possess in the lamina suprachoroidea a crystalline layer called the argentea, which is from its position not homologous to the tapetum; but in many deep-sea fishes a distinct tapetum exists in addition. Mr. Lee's observation on the position and use of the tapetum was valuable if such a position of the tapetum were found constantly in all animals possessing it. Against the view is the fact that many animals which undoubtedly needed a help of the kind that Mr. Lee supposed the tapetum to give—as bats, mice, and rats—did not possess it. The probability was that in these animals the retina is very sensitive to light, and that in those animals possessing a tapetum the retina is less sensitive. The use of the tapetum was probably to increase the stimulation of the retina in animals whose retinæ were not so sensitive as those who had no tapetum. Animals capable of good vision in a dim light were provided with irides having marked powers of contractility.—Mr. HENRY LEE, in reply, doubted whether deep-sea fishes had a real tapetum; there was very little light at the bottom of the sea, and so no need of black pigment. The tapetum was a distinct membrane from the choroid. The choroid may be coloured, as Hunter showed, but then it was not a true tapetum. He believed the tapetum was only of use for vision at short distances; it was always situate above the entrance of the optic nerve, and collected the dispersed light from the ground or from some near object.—Mr. BRUDENELL CARTER said that the giraffe fed from above, and this might explain why its tapetum was situate below the optic nerve.—Dr. B. O'CONNOR asked what was the microscopic structure of the tapetum.—Mr. JESSOP inquired for the evidence proving that the tapetum was altogether distinct from the choroid.

CLINICAL SOCIETY OF LONDON.

Ununited Fracture of Clavicle, with Symptoms of Writer's Cramp; Resection and Wiring of Fragments; Disappearance of all Symptoms.—A New Symptom of Megrim and Epilepsy.—Chronic Simple Ulcers of Stomach and Duodenum without Symptoms until the occurrence of Perforation.—Complete Recovery from Amaurosis of Malarial Origin.

AN ordinary meeting of this Society was held on the 22nd inst., Dr. W. Cayley, Vice-President, in the chair.

Mr. BARKER read a paper on a case of Ununited Fracture of the Clavicle causing Pressure on the Brachial Plexus and Writer's Cramp, for which excision of the false joint, with wiring of the fragments, was done, perfect union of the bone and complete relief of the nerve symptoms supervening. The patient was a boy aged twelve, perfectly healthy, and with an excellent family history. The right clavicle was found soon after birth to be broken. The labour was natural, and no accident happened to the child. The mother had had a fall on the ice when pregnant three or four months. Up to three years ago the condition gave rise to no inconvenience, though there was free mobility in the false joint which had formed. He then began to complain of pain down the right arm and a sense of weight in it. Two months before admission into University College Hospital he noticed, besides the pain, that his fingers became stiff and fixed over his pencil when writing. The fingers then tended to close, and he could not get them straight without a good deal of rubbing. On admission, the right clavicle was found to be an inch and a half shorter than the left, and the shoulder to be lower on that side. The inner end of the outer fragment dipped under and behind the outer end of the inner. The broken ends were rounded off and freely movable. He was set to copy out a sheet of foolscap, and in the course of a few minutes spasmodic movements were noticed in the hand, and at the end of half an hour his writing was totally illegible, and he could not unclose the hand, while the pain in the arm was severe. Rest in hospital did not give any relief, the result being always the same. A special examination by Dr. G. V. Poore showed "some wasting of the thenar eminence, and mottling of the skin of the right arm, which was also smaller than the left. No abnormalties of sensation were noticed, but the cords of the brachial plexus in the axilla and large nerve-trunks in the arm were found more tender than on the left side. The faradaic current showed reaction in all the muscles except the first right dorsal interosseous, which made no response to a weak current, but gave a good response on the other side." On August 26th, 1885, Mr. Barker raised a semilunar flap of skin and muscle from the clavicle, resected the false joint, and wired the cut surfaces together. All was done antiseptically, and the arm and shoulder were put up in a plaster-of-Paris corset. The wound was not touched for fourteen days, when it was found quite healed without a drop of suppuration; a moist spot remained where a catgut drain had been inserted. The dressings and corset were left on for a fortnight longer, and were then finally removed, the scar being sound and the bone firmly united with callus. Shortly after, he was set to do some writing as before, and all the former symptoms were found to have disappeared. The electrical examination showed a corresponding improvement, and the finger-nails now began to grow normally, a furrow marking the difference before and after operation. Since then the arm has rapidly regained strength, and all the symptoms noted have disappeared; it is now like its fellow in power. The rarity of ununited fractures of the clavicle was illustrated by an examination into the literature of the subject, all the recorded cases being collected. The present case was shown to stand alone, both in the phenomena exhibited and in the treatment and favourable result. The rapid and perfect union of the bones was attributed by the author, in a great measure, to the complete immobilisation of the fragments by the use of the plaster corset.—Dr. G. V. POORE thought that exception might be taken to the description of the nervous disturbances as those of writer's cramp. The case was, however, a good instance of the fact that slight degrees of weakness were best ascertained by the disturbance of delicate muscular actions. The serious disturbance in writing was due to pressure of the bone on the brachial plexus. The tenderness of nerve trunks in the arms was a conspicuous symptom in this case. A tender median nerve was exceedingly common in cases of writer's cramp in Dr. Poore's experience. The diminished irritability to the faradaic current that was noticed in the right first dorsal interosseous, which was the muscle *par excellence* of manual precision, was probably a secondary phenomenon, and due to the great effort that the boy had to make in order to write. The right pectoralis major was less developed than the muscle on the left side. As to trophic changes, there was slight mottling of the skin and slight grooving of the thumb-nail, and the left finger-nails grew very much more rapidly than those of the right. A further interesting point was the complete recovery from all the symptoms after the operation.—Dr. HUGHES BENNETT said he could not but agree with the previous speaker that much confusion arose from using the term "writer's cramp" indiscriminately. Writer's cramp was a peculiar general neurosis that set in as the result of exhaustion due to excessive writing. In Mr. Barker's case the local irritation of the brachial plexus disturbed the powers of writing by the cutting off of cerebral influences from the hand; but it was unlike genuine writer's cramp, which ran a totally different course, and was regarded by some as an incurable disease, though others asserted that by various measures a cure could be effected.—Dr. R. J. GODLEE congratulated Mr. Barker on the success of his surgery. In a conversation with Sir James Paget, that gentleman observed that he had only

Digitized by Google

seen two or three cases of non-union of bone dating from birth. Sir Wm. Fergusson had seen one of the cases, and had said there was no chance of obtaining a union; after this opinion Nélaton performed some operation in the same case, with only a temporary success, for the union broke down. In Sir James's second case amputation was resorted to, as all other measures failed. Mr. Godlee had seen one case in a child three years old, in which there was non-union of fracture of both bones of the leg; in this case resection had been performed twice without success.—Mr. A. E. BARKER, in reply, said he would not like to defend the expression "writer's cramp," but had used it for convenience of description.

Dr. ANGEL MONEY read a paper on a New Symptom of Megrim and Epilepsy. The patient in whom the new symptom was noted was a man aged twenty-nine. He had suffered from many of the symptoms that are usually put down under the heading of megrim, such as transient hemiopia, spots and flashes of light, headache with and without nausea, and abnormal tactile sensations. When about eleven years old he used to faint with a queer sensation at the epigastrium. The new symptom consisted in an apparent momentary lengthening of a written or printed word during reading, caused by a reduplication of one or more of the letters in the word. The patient observed that this annoying symptom was most frequent when the flashes of light were most troublesome. Another noteworthy fact in connexion with his visual organs was the long persistence of negative images, a condition which was not always present, but only at the times when he felt "bilious." There had never been convulsions or motor spasm of any kind; nor, with the exception above mentioned, has he ever lost consciousness. At times the patient was troubled with a ringing noise apparently in his right ear; he was, however, distinctly though not very deaf on the right side. Reflecting on this symptom of apparent lengthening of a word, it occurred to Dr. Angel Money to ask his patient whether he ever experienced a similar alteration in the length of spoken words. This was answered in the negative. There was no weakness of any ocular muscle, and only a trifling degree of myopia. The author remarked that there were many ways of interpreting this symptom. He did not think there was any fraud, or reasonable doubt that the symptom was a real one. Was it due to some transient disturbance in the muscular mechanism of the eyes? The author thought this supposition not at all improbable. But he considered that, theoretically, it must not be overlooked that we might have to do with a symptom belonging to what may turn out to be an altogether new field of sensory nervous symptoms, by which he meant a group of symptoms which might best be designated as "reduplicated sensory nervous actions." If the patient be right in his opinion that one of the letters of a word is doubled in the apparent lengthening, then it would not be at all absurd to regard the phenomenon as due to the reduplication of a nervous discharge in the visual word centre.—Dr. STEPHEN MACKENZIE said he did not gather whether the phenomena occurred whilst the patient was writing or at other times also. He had observed a similar thing in some cases of aphasia, in which there was a doubling or more frequent repetition of a sound, the phenomenon being known as "barrel-organism." The portion of the brain involved in the mechanism would be readily indicated if the phenomena described by Dr. Money were of this nature.—Dr. B. O'CONNOR said that he had observed something of a similar kind in a printer with whom he had considerable difficulty in the matter of correcting proofs. He thought such symptoms were not of infrequent occurrence in cerebral affections. Half a line may seem to some nervous people to be absent in reading. He did not know whether it was not a case of obtrusive observation of symptoms which at other times passed unnoticed.—Dr. ANGEL MONEY, in reply, said the phenomenon was purely subjective, occurring to the patient only during reading.

Dr. SAMUEL WEST read a paper on Chronic Simple Ulcers of Stomach and Duodenum without Symptoms until the occurrence of Perforation. Hannah A——, aged forty-eight, while eating, was seized with sudden severe pain in the epigastrium, which continued until her admission into hospital a month later. She had vomited, but food produced neither pain nor sickness. She had rapidly lost flesh and strength, and had recently perspired at night, and for a few days had had a cough which caused her pain in the right side and back. She had been all the time confined to bed, and a bedsore was found upon the right buttock a fortnight before admission. Though she had been losing strength lately, there was no history of any ailment before the present illness. There had never been any pain or discomfort after food. The patient looked very ill. The respiration was 46, shallow, with some general rhonchus; the pulse was 120; the temperature was 99°: the urine contained a trace of albumen; the liver was uniformly enlarged. Some tenderness was noted above the umbilicus and towards the right hypochondrium. There was no ascites, but some œdema of legs. Two days after admission, she passed with a stool about six ounces of dark blood, and also on the two following days. She rapidly became weaker, and died on the fifth day after admission. At the necropsy some old chronic pleurisy and pericarditis was shown to have existed. The liver was enlarged, with a superficial abscess between it and the abdominal walls. This abscess had two openings—one leading from the duodenum, and due to perforation of an old ulcer; the second into the colon, probably accounting for the hæmorrhage. Another large chronic ulcer was found upon the lesser curvature of the stomach, which had also perforated, and led into a cavity with thick fibroid walls, the base of which was formed by the liver. The two ulcers were of very old date, the symptoms being produced by the perforation of the duodenal ulcer and the formation of the abscess. Two points were noteworthy—1, the extent and duration of the ulcers without symptoms; 2, the lowness of the temperature in spite of active suppuration.—Dr. CAYLEY related the case of a healthy working man who died two days after admission to hospital. There was an ulcer of the duodenum that had burst into the peritoneal cavity. The man was certainly in the best of health till the onset of the perforative peritonitis.—Mr. TAYLER narrated the case of a servant, an anæmic girl aged twenty, who had no symptoms of gastric disease, and died very suddenly from an ulcer of the stomach that had perforated.—Dr. S. WEST remarked on the lowness of temperature in his case, notwithstanding the occurrence of suppuration.—Dr. S. MACKENZIE alluded to a paper in THE LANCET (vol. ii., 1885). In the fatal cases of gastric ulcer that occurred at the London Hospital for a period of ten years not one was recorded as without symptoms. But in 1874 Dr. Mackenzie met with such a case, in which death occurred in two days from the onset of symptoms of perforation.—Dr. F. J. GOODHART considered that cases of ulcer of the duodenum were in a different category from those of gastric ulcer. Duodenal ulcers were not very common, and probably owned the same pathology as gastric ulcers.—Mr. R. J. GODLEE referred to the case of a man who had a tumour in the femoral region that contained peritoneal fluid. The man was supposed to be suffering from lead colic. The hernial sac was found to contain highly offensive purulent fluid. The case did not progress satisfactorily, and the patient died with swelling of the parotid. An ulcer was found in the second part of the duodenum.—Dr. S. WEST felt quite certain that there was not even anything that could be called dyspeptic in his case. He had known a case of duodenal ulceration to be attended with considerable symptoms.

Mr. BRUDENELL CARTER read a case of Recovery of Vision after Amaurosis consecutive to Malarial Fever. The patient was a gentleman about thirty-five years of age, who was chief of the police in a West Indian colony. He came to the author on July 15th, 1884, his vision being then reduced to little more than qualitative perception of light. His history was that, in November, 1883, after very fatiguing duty in unhealthy parts of the colony, he was seized with a fever of malarial origin and malignant type, which nearly proved fatal. When he had otherwise fairly entered upon convalescence, his pupils remained widely dilated and insensitive to light, and it was observed that he had to feel for a feeding-cup or other object which was offered to him—a condition from which he made no advance. Mr. Carter found the optic nerves very white, as if from atrophy, and the larger vessels lifted up in bold curves as they crossed the margin of the disc, showing that the atrophy was consecutive to pre-existing swelling. The ophthalmoscope also showed hypermetropia 4 D, with some astigmatism. There could be no doubt that the fever had been attended by optic neuritis, probably connected with meningeal trouble, and that vision was being destroyed by the contraction of effused material. Notwithstanding the unfavourable prospects of the case, the author determined to carry out the plan of treatment which he had several years ago laid down as

Digitized by Google

appropriate for similar conditions—namely, to endeavour to promote the absorption of effused material by mercury and iodide of potassium, and to stimulate the nutrition of the optic nerves by strychnia. The patient wished to take up his temporary residence in Birmingham, and Mr. Carter had the good fortune to obtain the co-operation of Mr. Bartleet in carrying out the necessary measures. Perchloride of mercury and iodide of potassium were administered by the mouth, in moderate doses; and sulphate of strychnia hypodermically, in doses which commenced with one-sixtieth of a grain, and were gradually increased to as much as one-seventh, when the injections were followed by stiffness and rigidity of the muscles of the legs, and the dose was necessarily reduced. On Aug. 4th, or rather more than a fortnight after the commencement of the treatment, the patient reported that although he could not see to read or write, he thought he had improved in sight as far as concerned general objects, and he was thereupon encouraged to persevere. In another month the improvement was no longer doubtful, and after five months of treatment, in December, 1884, the error of refraction being corrected by suitable glasses, he was found to have one-third of normal vision, and to be able to read No. 6 of Jaeger in the hand. On Jan. 10th, 1885, Mr. Carter received a letter from him in perfectly good and legible handwriting, except that the lines were uneven and irregular. In this letter he said, "Will reading the newspaper by gas-light hurt my eyes? After reading a little time the words appear as if coming out of a fog, if I may so describe it, and occasionally a sort of flash of colours (similar to colours which appear on cut glass when the sun shines upon it) comes before my eyes. It is, however, a great comfort to be able to read at all." By March 20th, 1885, his vision had increased to one-half, and he read No. 2 of Jaeger. By July 21st vision had reached two-thirds, and in another month it was normal, and No. 1 of Jaeger was read easily. The patient was not conscious of any remaining impairment, except that he saw badly on coming from a stronger light into a weaker one, as if the retina required a decided stimulus. At this time the optic nerves were still pale, but many small vessels, previously invisible, were to be seen upon their surfaces. The patient wrote in even lines, and in the following month he returned to his official duties. At a somewhat late stage in the course of the treatment it became necessary to relinquish the hypodermic injections, in consequence of every puncture having for some time past become the seat of painful inflammatory swelling; and, from thenceforward, the strychnia was given by the mouth, alternately with mercury and iodide. The author remarked upon the great perseverance of the patient, and bore grateful testimony to the way in which he had been assisted and supported by Mr. Bartleet.—Dr. S. MACKENZIE said that in this country cases of malaria were not accompanied by optic neuritis, but in countries where malaria was both frequent and severe optic neuritis was more common, as Dr. Hammond had pointed out. The value of treatment by iodide of potassium was to be witnessed even in cases of cerebral tumour, where the optic neuritis could be seen to subside, though the patient died from the effects of the tumour. He inquired with what object strychnia was given subcutaneously, and asked why it might not have been combined with the other medicines. It was rare to meet with cases of optic neuritis, in which the deterioration of sight was so great as in Mr. Carter's case, that improved so markedly by treatment.—Dr. J. ANDERSON inquired for a history of syphilis, and also as to the state of the optic discs when the patient was last seen.—Dr. S. COUPLAND mentioned the case of optic neuritis that Mr. Henry Jones had so greatly relieved by a course of mercury.—Mr. B. CARTER, in reply, said that by employing the hypodermic method of administration of strychnia he obtained more trustworthy results than by administration by the mouth. The patient was a gentleman of high official position, and of decorous conduct and wholesome life, and there was no history of syphilis. The patient had suffered from ocular troubles due to hypermetropia, and was a moderate smoker. The optic discs were still pale when last seen, and the small vessels were reappearing. Mr. Carter believed that strychnia acted as a stimulant to the nutrition of the optic nerves.

The following living specimens were shown:—Dr. Stephen Mackenzie: A case of Elephantiasis of the Leg. Mr. R. W. Parker: Congenital Tumour in Lumbo-sacral Region, containing Bone. Mr. A. E. Barker also showed the boy whose case he narrated.

MEDICAL SOCIETY OF LONDON.

Theory of Fever.—Pyæmia after removal of Sarcoma from Base of Skull; recovery.

AN ordinary meeting of this Society was held on Monday last, Dr. W. M. Ord, President, in the chair.

Dr. THUDICHUM read a most elaborate and abstruse paper on the Theory of the Febrile Process, its accompanying Chemical Changes, and the Modes in which it produces Immunity from further Attacks and Death. He believes that an alteration in the atomic volume of bodies is a considerable factor in the development of heat. In febrile processes the atomic volume appears to undergo contraction with the appearance of free heat. Immunity from further synochal disease is to be explained also on the same assumption, for the atomic volume of the tissues remains more or less permanently diminished in dimensions. Speaking of the mode of death in fever, Dr. Thudichum considered that death was sometimes to be explained on the assumption of a coagulation of certain complex chemical bodies called phosphatides, and resembling, though not identical with, phosphates. Amidomyelin, one of these complex bodies derived from brain-substance, has the property of passing into the solid state by the application of a fever heat, say about 40° C. or 104° F. In certain frigid conditions, such as pertained in cholera, a fluidification of colloids took place, with the necessary production of cold. Dr. Thudichum considers therefore that pyrexia is due not only to excessive oxidation or abnormal accumulation, but also to some peculiar molecular alteration of the tissues, which, indeed, would appear to be in his theory the most important factor in showing us how it was that fever conferred immunity from further attacks of the same fever, and even, according to the author, immunity to a less degree from all fevers. Vaccination, Dr. Thudichum suggests, may not only prevent the development of small-pox, but even render the body less liable to become the seat of other acute specific fevers.

Mr. WALTER PYE read a paper on a case of Removal of Sarcoma of the Base of the Skull followed by Pyæmia, but ending in recovery. A male patient aged sixteen was admitted into St. Mary's Hospital on June 22nd, 1885. Bleeding from the throat and left nostril for eighteen months was the chief symptom. A growth behind the soft palate blocked the left nostril, interfered with deglutition, and caused several alarming attacks of dyspnœa. Preliminary tracheotomy was performed on June 24th, and the pharynx having been plugged, the soft palate was divided in the middle line; the tumour was then found to have wide connexions with the basilar process of the occipital bone, and possibly to the atlas. A stout cord of twisted wire was used to cut through the broad base of the tumour by means of a large screw écraseur, which was manipulated through the nostril. One hour and a half was spent in dividing the tumour, which was exceedingly vascular. The hæmorrhage was checked by ice. The patient left the hospital apparently well twenty-six days after the operation. The tumour was a myxosarcoma. Ten days after his discharge he was readmitted with a temperature of 105·4°, with pain in the shoulders, knees, wrists, and one ankle. His illness resembled an acute attack of rheumatic fever rather than a pyæmia. The patient remained very ill for two months and a half. The joints remained swollen and became purulent when they were opened, discharging thin curdy pus. A large ulcer formed in the muscles of the right thigh, and another in the gluteal region. Abscesses appeared and disappeared till the end of October, since when he has made a slow but steady recovery. The unusual nature of the operation, its successful issue, and the possible connexion between the operation and the pyæmia, were made the subject of remarks. The employment and manipulation of the écraseur through the nostril was the only practicable method of operation in the case in question. Mr. Pye considered the subsequent illness as of a pyæmic nature.—Dr. THUDICHUM had had two cases in which he had operated; bleeding was very severe, but was controlled by the galvano-cautery and perchloride of iron.—Dr. KINGSTON FOWLER asked what the microscopical nature of the tumour was, and whether the spleen or liver was enlarged.—Mr. W. PYE replied that there was no visceral enlargement; the growth was a myxosarcoma. He should not have used perchloride of iron in his case.

HARVEIAN SOCIETY.

Annual Meeting and Conversazione.

THE annual meeting of this Society was held on Jan. 21st, at the Stafford Rooms, Titchborne-street, Edgware-road, and was largely attended. The business of the evening included the adoption of the report of the Council, and the election of officers for the ensuing year, of which the following is a list:—President: *J. Hughlings-Jackson, M.D., F.R.S. Vice-Presidents: Malcolm Morris, Esq.; Charles Vasey, Esq.; *T. Bryant, Esq.; *J. Cavafy, M.D. Treasurer: Thomas Buzzard, M.D. Honorary Secretaries: J. Ernest Lane, Esq., *E. Clifford Beale, M.B. Council: G. C. Field, Esq., F. Otley Lovell, Esq.; P. Kirkpatrick Picard, M.D.; W. H. Platt, Esq.; Henry Power, Esq.; T. Gilbart Smith, M.D.; John Williams, M.D.; *J. S. Brookfield, M.D.; *Arthur W. Edis, M.D.; *W. Ewart, M.D.; *T. Morton, M.D.; *H. W. Page, Esq. (An asterisk is prefixed to the names of those gentlemen who did not hold the same office the preceding year.) The thanks of the Society were voted to the members of the Council on the motion of Mr. Adams, seconded by Mr. Bartleet; Mr. Vasey replied. A vote of thanks to the Treasurer was proposed by Mr. Adams Frost, seconded by Mr. Noble Smith, and acknowledged by Dr. Buzzard. Dr. Sansom, seconded by Dr. Felce, proposed a vote of thanks to the Secretaries, to which Dr. Ewart replied. The vote of thanks to the retiring President, Dr. T. Morton, proposed by Dr. Buzzard and seconded by Dr. Davson, was carried by acclamation. In his reply, Dr. Morton congratulated the Society upon its increasing prosperity and usefulness. After a brief review of the work of the past year he proceeded to deliver the annual address. The subject was one of wide and practical interest—the Relation of Public Morals to the Public Health,—and was eloquently treated by the orator, who concluded amidst the applause of the meeting. The new President, Dr. Hughlings Jackson, took the chair vacated by Dr. Morton, and, having accorded to the latter the thanks of the Society for the address to which they had listened, declared the conversazione open. The room was tastefully decorated, and contained many objects of interest lent by members and their friends. Music had been provided, but Mr. Lazarus kindly added two solos on the clarionet to the programme which had been announced, and gave the audience a musical treat, which possessed the additional charm of being a surprise.

CAMBRIDGE MEDICAL SOCIETY.

Disease of Finger-nails.—Faith-healing.—An unusual case of Broken Neck.

AT a meeting of this Society held on December 4th, 1885, Professor Humphry, M.D., F.R.S., in the chair,

Mr. LAURENCE HUMPHRY showed a patient, aged fifty-three, a married woman, suffering from a peculiar Disease of the Finger-nails. All the nails of both hands were attacked with very accurate symmetry, but not the feet. The nail was opaque, thickened and heaped up, the edges and surface broken up, irregular, and filled with dirt. The patient described it as commencing under the free edge of the nail, and then working round to the root, the nail becoming black, split up, and finally coming off. It was accompanied by a hot itching sensation, and tingling and numbness down the sides of the fingers. There was no skin eruption, or soreness by the side of the nail. Her history gave no evidence of gout or syphilis. Mr. Laurence Humphry referred to Plate 17 of Hebra's Atlas of Skin Diseases, where a similar condition was figured, and described in the catalogue as "Chronic General Onychitis."

Mr. HODGSON (Bishop Stortford) related two cases of Recovery from Empyema, in which the aspirator had been used; and a case of Pleurisy with an unusually large serous effusion, which had been treated in the same way.—A discussion followed, in which Dr. Paget, Mr. Carter, Mr. Laurence Humphry, and others took part.

Dr. RANSOM read the notes of a case of so-called Faith-healing. A married woman, about forty-five years old, in comfortable circumstances, was operated on in January, 1882, for cancer of the breast. She made a good recovery but the disease returned in the cicatrix some twenty months later, and also in the other breast and abdominal organs. Her health and strength gave way, and she became much depressed, and ceased to carry on her ordinary duties in the household. After a while she was induced by her friends to try the system of "faith-healing," but after studying the books and letters published by its advocates she could arrive at no decision for some time, till one day in June, 1885, she sent to Dr. Ransom and told him she was well, that the pain was gone, and that she was going to London to join the faith-healing sect. From June until September she went about proclaiming herself cured, and that her faith had made her whole. She gained flesh and strength, became cheerful, and resumed her household duties. In September, however, she sent for Dr. Ransom, being attacked with peritonitis, and she expressed the greatest disappointment at finding that she was not so well, and saying that she had fully believed herself to be cured. Dr. Ransom said that this was a remarkable illustration of the power of mind over matter. That she really did believe in her own cure was obvious, for otherwise how was it possible to explain the remarkable change not only in her mental but in her physical condition, her freedom from pain, and renewed bodily activity? She was not influenced by personal contact, but by studying the subject and by prayer.

Mr. FRANCIS was able, through the kindness of Mr. Carver, under whose care the patient was, to bring forward a somewhat unusual case of Broken Neck. The patient, aged fifty, was admitted into Addenbrooke's Hospital on October 8th, 1885. He had fallen backwards off a ladder, a distance of twenty feet, striking the upper and back part of his head against a plank. He was unconscious for a few minutes, and on recovering his senses was found to have lost the use of his limbs. He lay in bed with his head thrown slightly back and fixed by muscular effort in the middle line, rotation causing pain. He had perfect control over his sphincters, and his pupils were equal. Paralysis was complete in both upper limbs and the left lower limb, and there was slight loss of sensation. Examination of the spine revealed no evidence of displacement, nor was there any pain in the cervical region, but he complained of pain about the third and fourth dorsal spines. Pulse 80; temperature 97°. Urine acid; no albumen. For a month he made steady progress, had regained much power in his limbs, and the anæsthesia had disappeared. His head still remained fixed, and he was much troubled with constipation. On November 4th, there was a sudden change for the worse; the temperature was considerably raised, and suppuration manifested itself; profuse acid sweats, and acute migratory pains and tenderness in the joints succeeded, and finally effusion took place into the right knee-joint. He became delirious at night, and suffered from constant pain at the back of the neck. The paralytic symptoms returned and in four days was complete, and he lost control over his sphincters; bedsores rapidly developed, and he died thirty-seven days after the accident. At the necropsy small collections of pus were found between the muscles of the neck. The posterior part of the ring of the atlas was broken off and was freely movable; the line of fracture on both sides passed just behind the groove on the vertebral artery. The axis was also fractured, but the fragments were not movable on one another, the line of fracture passing through the posterior part of the atlanto-axial articular surfaces, between the pedicles and the body of the vertebra, the arch being separated from the body. There was no displacement, and no sign of repair. There was no evidence of hæmorrhage or pus within the meninges, and no signs of pressure on the cord or injury to the medulla. The heart and lungs were natural.

HEALTH LECTURES.—Sir Andrew Clark, Bart., F.R.S., Lord Randolph Churchill, Sir Frederick Pollock, Bart., and other influential friends of health, have, we understand, promised to take part in a comprehensive course of Health Lectures organised by the National Health Society, to commence on the 29th inst., at the Public Baths, Queen's-road, Bayswater. One novel feature to be introduced, with a view to enforcing the Society's motto, "Prevention is better than cure," is a simple description of the causes of disease and the way to avoid them. The lectures will begin at 8 P.M., in order to allow those engaged during the day to attend.

Reviews and Notices of Books.

A Practical Treatise on Fractures and Dislocations. By FRANK HASTINGS HAMILTON, A.B., A.M., M.D., LL.D., late Professor of Surgery in Bellevue Hospital Medical College, and Surgeon to Bellevue Hospital, New York, &c. Seventh American Edition, revised and improved. Illustrated with 379 Woodcuts. London: Smith, Elder, and Co. 1884.

Fractures and Dislocations. By T. PICKERING PICK, F.R.C.S., Surgeon to and Lecturer on Surgery at St. George's Hospital, Member of the Court of Examiners, Royal College of Surgeons of England. Illustrated with 93 Engravings. London: Cassell and Co., Limited. 1885.

ALTHOUGH dealing with the same subjects, and treating of them in a very closely similar order, these two books are by no means alike in design and worth. Dr. Hamilton's work on fractures and dislocations is one of the modern surgical classics which presented when published the only treatise on this subject in the English language which was at all complete. It was then the result of very extended literary research and much practical observation, and, as edition after edition has been called for, its distinguished author has with unstinted labour endeavoured to incorporate into it the results of the work and observations of other surgeons, and to make it as far as possible an exhaustive treatise on this important branch of surgery. And though, in view of the progressive nature of our science and art, it is certain that finality has not been reached, yet it is impossible for a reader of Dr. Hamilton's work not to be impressed with the great amount of labour and care he has bestowed upon it, or to be unconscious of the conspicuous value and merit of the volume, which is, and will probably long remain, the standard treatise on fractures and dislocations in the English tongue.

Mr. Pick's book is one of Messrs. Cassell and Co.'s clinical manuals—an unpretentious volume of 500 small pages, in which the author has sought to present to his readers a "concise and practical treatise of the causes of the various fractures and dislocations, the signs by which they may be recognised, and the appropriate treatment to be adopted for their cure." We believe that candid readers of the volume will feel that in this Mr. Pick has succeeded. The description of these injuries is in all cases clear, although brief, and the subject is everywhere presented in a practical manner. The scope of the work has rendered it necessary that it should be dogmatic to a certain extent, but throughout opposing views are dealt with in a broad and liberal manner. This is by no means a drawback, for the readers of such a manual seek for guidance from the writer's own experience. We can therefore commend Mr. Pick's work highly. At the same time, it is open to question how far the work meets any felt want, and how far it owes its production to the determination of Messrs. Cassell and Co. to publish a series of clinical manuals, which would not be complete without one devoted to fractures and dislocations. We find, for instance, that in the last edition of Erichsen's Surgery almost as much space is devoted to this subject as the whole of Mr. Pick's manual, and the discussion of it is nearly as full; so that a reader of the larger work would have no need to supplement his knowledge by consulting this special manual. Good as the work is, it is therefore open to doubt how far the publishers' anticipation of its success will be realised.

The order in which the subjects are discussed in the two works under review is so closely alike that it might almost appear that one was borrowed from the other, were it not evident that the subject hardly admits of any other order of discussion; and it is quite apparent that Mr. Pick has in no way derived more from Dr. Hamilton than any writer must who avails himself of the latter's elaborate treatise. It is interesting to note how one or two points that are much discussed are dealt with by the two authors. Thus, with regard to the immediate treatment of fractures by the application of immovable apparatus such as a plaster-of-Paris casing, Dr. Hamilton says: "The immovable apparatus, of whatever materials constructed, is under some circumstances a very simple, safe, and efficient dressing, while under other circumstances it is, as we think, eminently unsafe and inefficient. ..... Whatever its advocates may say to the contrary, the simple fact is before us that the number of accidents resulting from this practice is out of all proportion with any other yet introduced." He further on specifies the cases for which he considers it safe or unsafe. Mr. Pick says: "In the majority of fractures, however, we shall, I think, be best consulting the welfare and interests of our patient by not applying the immovable apparatus until after the subsidence of all swelling." In reference to the treatment of compound fractures, when the wound is of such a nature that its union by "primary adhesion" is not to be expected, Mr. Pick says: "Under these circumstances there is no plan of treatment which will give such favourable results as the antiseptic treatment of Sir Joseph Lister." Dr. Hamilton is, however, "far from being convinced that, in the case of compound fractures or of other wounds," the Listerian treatment "is capable of doing all that is claimed for it..... In short, if the method of Mr. Lister has any advantages—and it no doubt has,—these advantages consist in the continuous application of a mild stimulating lotion, &c., and not, as has been taught by some surgeons, exclusively, or even mainly, in the employment of an antiseptic." Most of our readers will agree that the English author has expressed a sounder estimate of the value of antiseptic surgery in the treatment of compound fractures than his American *confrère*. Nor is the reason far to seek, for Dr. Hamilton's description of the Listerian dressing scarcely bears evidence of a thorough familiarity with its precise details. After noting this divergence of views we will quote Dr. Hamilton's opinion on the use of a metallic suture for primary simple fracture of the patella. After quoting many opinions adverse to this procedure, he says: "To the testimony thus accumulated against this operation I wish to add my own—that it is offering a very grave and dangerous substitute for others perfectly safe, and, so far as is yet proven, equally efficient methods; it is hazarding the life of the patient without offering any equivalent." Mr. Pick says: "I would not consent to have this operation performed on myself, and I do not, therefore, feel justified in recommending it to my patients." From this view very few surgeons either in Europe or America will now dissent.

We have been disappointed in not finding a notice in Hamilton's work of fracture of the shaft of the femur by torsion; and his account of subastragaloid dislocations of the foot is far from complete and singularly out of proportion with the long descriptions of dislocations of the astragalus.

OUR LIBRARY TABLE.

Manuel des Injections Sous-cutanées. Par MM. BOURNEVILLE et BRICON. 2e Edition. 1885.—*Manuel de Technique des Autopsies.* Par MM. BOURNEVILLE et BRICON. Paris: Delahaye et Lecrosnier. 1885.—These two compact and handy little books belong to the series of *Publications du Progrès Médical*, and have been compiled with a care and completeness that must render them of considerable utility. The manual on subcutaneous injections opens with a description of methods, instruments, precautions, &c., and then deals in turn with every drug that has been at one time or another prescribed for administration in this manner, the authors prudently refraining from endorsing many of these medicaments

Digitized by Google

with their personal recommendation. The alphabetical arrangement of the articles greatly facilitates reference, and we have no hesitation in commending the book to notice. The other manual deals with its subject in two parts; the first being devoted to a recital of the regulations for post-mortem examinations in France and abroad, and a comparison of the facilities afforded, with many other details of administration, means for instruction, &c.; whilst the second part is that which gives the title to the work, the several stages of a complete autopsy being fully detailed. As may be expected, preference is given to the method of examining the brain by vertical sections, and reproduction of Pitres' well-known figures illustrate this portion of the work. The plans of pathological institutes of the best and completest type are appended. The authors do not seem to have inquired much into the practice of British institutions (with the exception of Edinburgh), but they contribute some interesting information upon various continental institutes—viz., as to post-mortem examinations being compulsory or not; and we cannot forbear quoting the following statement: "A Edinbourg, l'autopsie n'est pas obligatoire, les parents et les amis peuvent s'y opposer. Les Catholiques s'opposent généralement à l'autopsie, mais cette opposition peut-être levée par le prêtre à la demande du médecin." We learn also that in Paris and in some other continental cities post-mortem examinations are forbidden upon members of the Jewish community; and the facts on this head and others have evidently been collected with the laudable desire to get rid of certain restrictions which obtain in Paris.

University College Hospital and St. Bartholomew's Hospital Reports.—The first of these volumes deals with the surgical and medical cases that have been treated in the hospital during the year 1884. It is without exception the most complete and detailed report that has ever been issued from this hospital. The labour which has evidently been spent in its production reflects great credit on its chief author, Mr. Bilton Pollard. The medical cases at this hospital, as at so many other institutions, are given simply statistically. We think this is to be regretted. The surgeons at University College must feel the value of so exhaustive a guide to the surgical work of the past year. Such a report as the one before us practically does away with the necessity of referring to the case-books, for all the important and interesting cases are carefully recorded in detail. Considerable judgment has been exercised by the author in the selection of cases for detailed treatment. The labour attendant upon the production of hospital reports is so great that by common consent criticism has always been of the most tender description, though there has often been room for it. Mr. Bilton Pollard's report, however, would stand the test of severe criticism.—The report of St. Bartholomew's Hospital consists of statistical tables of the patients under treatment during 1884. Its scope is not the same as that of University College Hospital, still a large amount of information has been brought together by its authors, Dr. S. West and Mr. A. A. Bowlby. In the surgical appendix we observe that there were three cases of varicella gangrenosa and three of hydrophobia. Several of the more interesting cases have been reported in the journals and at the Societies.

Handbuch der Physiologischen Optik. Von H. von HELMHOLTZ. Zweite Auflage. Erste Lieferung. Leipzig: Leopold Voss. 1885.—The first edition of this valuable work in the original [illegible] has long been exhausted, and even the French [illegible] has become exceedingly rare; it is therefore with great pleasure that we welcome the first instalment of the second edition. The author states in his preface that he has himself been unable to verify all the more important facts given, as he had the time and ability to do for the first edition; but he has endeavoured to incorporate all the essential points of progress that have accumulated in the course of the last twenty years. He has thus been enabled to make many of his former statements more clear, and to corroborate them by recently ascertained facts when they required support. Many of the illustrations have been replaced by newer and better ones. The present part, extending to eighty pages, is chiefly occupied with the anatomy of the eye. The ophthalmometer is described, and an account given of the mode of ascertaining the precise curvature of the cornea. The remainder is occupied with the commencement of the subject of physiological optics.

Histoire du Choléra aux Indes Orientales avant 1817. Par J. SEMMELINK. Utrecht: C. H. E. Breijer.—Dr. Semmelink, who was formerly principal medical officer to the army in the Dutch eastern possessions, has compiled an interesting work on the history of cholera in the East prior to 1817. Much of the work had been done before, and the author quotes largely from many English physicians and surgeons who had studied and written on the same subject. Dr. Semmelink holds to the view that Asiatic cholera had existed from time immemorial in what now constitutes British India, and that it was only in 1817 that it quitted its normal abode to spread into Asia and subsequently into other parts of the world. The work, which does not profess to be much more than a compilation, dives into the most ancient literature relating to the subject, and will be useful as a book of reference to all who are interested in the history of cholera.

Under the Red Crescent; or, Ambulance Adventures in the Russo-Turkish War of 1877-78. By R. B. MACPHERSON. pp. 213. London: Hamilton, Adams, and Co. 1885.—This volume gives a very readable account of the scenes through which Mr. Macpherson passed during a service of about five months as surgeon with the Red Crescent Ambulance in Bulgaria in 1877-78, and the hardships which the medical officers endured. His description of the treatment they received from the Russians when taken prisoners by them at Sofia is anything but flattering to the officers of that army. The personal adventures of the author form the chief subject of the book, and no details are given of the professional work done by the medical staff of the ambulance.

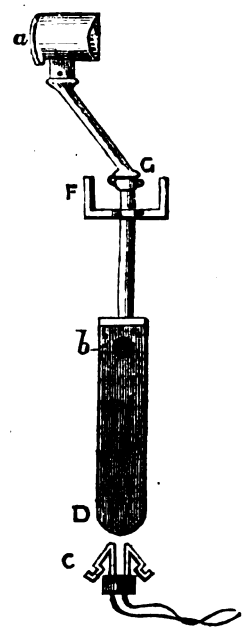
Hints on the Use and Handling of Firearms. By Lieut. H. O. CURLING. pp. 42. London: Dulau and Co. 1885.—A study of this little work, and compliance with the instructions given in it with regard to the handling of firearms, would undoubtedly have a beneficial effect in reducing the number of accidents which unfortunately result so frequently from ignorance and carelessness. The necessary precautions are clearly laid down and easily carried out.

New Inventions.

THE ELECTRIC LIGHT APPLIED TO THE OPHTHALMOSCOPE.

THE incandescent form of electric light is so convenient in many ways, that it is not surprising to find it has been adapted to sundry medical instruments. To adapt it to the ophthalmoscope I finally decided upon the following plan—viz., to fix a small incandescent Swan lamp close to the oblique mirror of an ophthalmoscope, arranged in such a way that the light from the lamp should be reflected to a focus in a direct line with the sight-hole, so that the brightest illumination should always be exactly in front of the sight-hole. As the lamp is fixed to the ophthalmoscope and moved with it, it follows that the relation of the illuminated spot and the sight-hole never varies. For helping me to carry out this idea into detail I am

Digitized by Google



much indebted to the skill of Mr. Panton, of the firm of Messrs. Pickard and Curry. The electric lamp and handle I have had adapted to Morton's ophthalmoscope, but such an arrangement could be adapted to any ophthalmoscope.

The construction of the instrument is simple, as can be seen by a glance at the accompanying woodcut. Fig. 2 shows the small cap (*a*) which encloses the Swan lamp. The cap is silvered on the inside with a reflector, seen shaded dark in Fig. 1. The Swan lamp is in the middle of the cap, and in front is a small bull's-eye lens which concentrates the light on the mirror. This cap is covered externally with wood, so as to insulate the heat from the lamp, which becomes hot if kept at full incandescence for ten or fifteen minutes. The Swan lamp is so fixed as to be easily removed and replaced by another, in case of any damage. The wires from the lamp are carried down within the handle, and entirely concealed from view. Contact with the battery is made by pushing a little contrivance (C) into the end of the handle (D). It holds by the little notch seen on each side (*e*). It can be at once detached by pressing the two little projections at the side seen at *e*, Fig. 1. This avoids the delay and inconvenience of

FIG. 1.

FIG. 2.

having to screw and unscrew the connexions. Any of the flexible conductors may be used to make contact with the battery. The button (*b*, Fig. 2) enables the surgeon to turn the light on or off, as desired. In Fig. 2 (F) is shown the means for fastening the handle with the electric lamp to the ophthalmoscope. The two pins slip into two spring clips added to Morton's ophthalmoscope. A collar (G, Fig. 2) enables the handle to be rotated, and thus the lamp can be turned to the right or to the left side of the mirror, so as to suit the examination of the right or left eye of a patient. A small catch (G) stops the rotation when the lamp is in proper position. This is the whole arrangement about the lamp. The only additions I have made to Morton's ophthalmoscope are the two clips already mentioned, and an oblique mirror of short focus, with a sight-hole oval laterally. This mirror fits into the clip, where the larger mirror of the ophthalmoscope is placed. This smaller mirror is set so that it lies at an angle of 45° to the plane of the ophthalmoscope. Thus, when the lamp is fixed at the side thereof, parallel to the plane of the ophthalmoscope, it follows that the light is focussed exactly in a line with the sight-hole. Fig. 1 shows the instrument adjusted for examination of a patient's left eye, since it is convenient to have the lamp to the outer side of the eye under examination, otherwise the patient's nose would come in its way. To adjust it for examining the patient's right eye, all that is necessary is to rotate the handle of the lamp to the opposite side, till the catch (G, Fig. 2) stops it. It is then in the same plane as the ophthalmoscope. The oblique mirror, of course, has to be turned round, so as to face the lamp. In doing this I find it is best to look straight down the sight-hole, keeping the eye about eight to ten inches from the mirror, and to turn it till the image of the incandescent filament appears round the sight-hole.

This instrument is intended for the direct method of examination of the eye, and is used precisely in the same way as the ordinary ophthalmoscope. The light is pleasant, and quite as well borne as the usual gas or lamp light used in ophthalmoscopic examinations. By this arrangement it is easy for an inexperienced person to see the fundus oculi, and especially so if the pupil be dilated. The light is on the spot he looks at, and always follows the movements of the instrument. The light is never lost. On this account it may prove a useful demonstrating ophthalmoscope. The colour of the parts is nearer that seen by daylight than can be got by the ordinary artificial light. The lamp can be detached in a second, and used independently for oblique illumination in examining the cornea or lens. I have used this lamp in needling operations. The ophthalmoscope can be used in the ordinary way, since the oblique mirror can be removed, the additions in no way interfering with it.

As to the source of the current, I have used lately four cells modified Leclanché battery. This gives a moderate light for about eight minutes, and then requires twenty minutes' rest. The bichromate battery, as employed at Moorfields Eye Hospital is probably the best form of stationary battery. Two small Grove cells will give a good light with this lamp for three or four hours or more. Pocket accumulators have hitherto disappointed me. Mr. Joseph Swan has recently made a reliable accumulator, which is quite portable, and, fixed with a specially constructed Swan lamp, gives a good light for twelve hours. It can then be re-charged. Mr. Swan is now perfecting these accumulators still further, and it is very probable that medical men will then be provided with a portable and trustworthy source of electric current, which will not only be useful for lighting purposes, but also for galvano-cautery, &c.

J. MCKENZIE DAVIDSON (Aberdeen).

THE TREATMENT OF PERTUSSIS.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Cory's remarks on the above subject in your issue of the 9th inst., and especially with regard to the antiseptic treatment of the same, I am very pleased to have this opportunity of corroborating his view and of adding a view of my own. I would suggest that the carbolic acid, or anything else which is used, should be in the form of a spray. The carbolic acid may be very successfully given by means of an ordinary steam spray, simply allowing it to be diffused through the apartment. A solution of 1 in 20 will be found very suitable, and this should be directed towards the patient's face and as near the face as may be found agreeable. By this plan no internal drug should be necessary so far as the pertussis is concerned. The system, if judicially carried out, ought to cut short an attack in an individual, and it will at the same time act as a disinfectant generally. These remarks so far have a special bearing on pertussis, but they will be found equally applicable in many other diseases, such as measles, scarlatina, croup, diphtheria, and phthisis, or any other affection of the air-passages. I consider this idea, when properly carried out, will open up a new field in the treatment of disease generally, and the above may come within the range of the surgeon. I have adopted this system in a number of cases, and found it most satisfactory as far as the patient was concerned, but not so very satisfactory (from a financial point of view) for me.

I am, Sir, yours respectfully,

Bury, Lancashire, Jan. 13th, 1886. GEO. C. RICHARDSON.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, JANUARY 30, 1886.

THE Profession is under a deep debt of gratitude to Dr. WILLIAM OGLE for the paper read before the Royal Medical and Chirurgical Society on Tuesday evening, on Mortality in the Medical Profession. We commend it to the deep study of every medical practitioner, especially those portions of it with which he may feel least pleased or which he may regard as least creditable to the profession. The science of statistics is a very impartial one, and in the hands of Dr. OGLE we may be sure that nothing has been set down in malice to the profession of which he is a distinguished member. We have only therefore to be grateful to him for a contribution of deep significance to the statistics of the profession. Statistics, though impartial, are capable of being so grouped and crystallised as to convey wrong impressions. We may hope that further investigation and criticism will show that this is the case with regard to some of Dr. OGLE'S conclusions. But we shall do well to assume that in the main they contain a good deal of truth, and impress on the physician to regard his own health with that of his patient as being equally within his responsibility.

Our readers will peruse the carefully prepared abstract of Dr. OGLE'S paper (published in another column) for themselves, and they will see that his account of the mortality of the profession is on the whole unsatisfactory. According to his tables that mortality is high, and is increasing. It was not only higher in 1880-1-2 than that of other callings and professions, but higher than that of medical men twenty and ten years before—in fact, a progressively increasing mortality. While the mortality of the legal profession in 1880-1-2 was 20·23 per 1000, and that of the clerical profession only 15·93, that of the medical profession was 25·53. Compared with other callings—with trades not very favourable to health—the medical profession is more deadly. Thus, the mortality of medical men is greater than that of teachers of the same age, commercial travellers, bakers, shoemakers, printers, bookbinders, masons, and coal-miners. It is less than that of innkeepers, brewers, butchers, earthenware manufacturers, cotton, woollen, and worsted manufacturers, painters, plumbers and glaziers, cutlers, and quarrymen.

Dr. OGLE has with much pains prepared a table of a unique character on the Causes of the Deaths of medical men. The material for this table has been got from copies of the entries in the Death Register relating to medical men, which registrars are paid to send to the General Medical Council. One fact of much interest is that in 1880-1-2 there were 1156 deaths of medical men in England and Wales. This may be taken for practical purposes, as a measure of the actual [illegible] the profession in this division of the kingdom. We may consider it settled that 385 deaths of medical men occur yearly in England and Wales. If we consider the mortality of medical men in Scotland and Ireland [illegible] to double this number—which is an extreme supposition—this would give us a loss of 770 medical men in the United Kingdom by death, a number which is exceeded by hundreds every year of additions to the Register, and one which falls short of Dr. PLAYFAIR'S estimated waste of the profession by about 800! Still, Dr. OGLE'S statistics, and especially his interesting table in which he gives the comparative mortality of medical men over twenty and that of other males in the general population of similar age, remain to be considered. We can only here indicate its principal points. According to it, medical men die in much larger proportion than other men of corresponding age of the following chief diseases. The two figures after the disease mentioned show at a glance the deaths per 1,000,000 of medical men and of all other men respectively—thus: scarlet fever, 59, 16; typhus, 79, 38; diphtheria, 59, 14; enteric fever, 311, 238; malarial fever, 46, 11; erysipelas, 172, 136; alcoholism, 178, 130; gout, 291, 78; rheumatic affections 251, 215; malignant disease, 879, 790; diabetes, 284, 108; diseases of the nervous system, 4565, 4268; diseases of the circulatory system, 4142, 2934; liver disease, 1744, 744; other diseases of the digestive system, 973, 632; calculus, 86, 39; diseases of bladder and prostate, 634, 287; other diseases of the urinary system, 1520, 665; suicide, 363, 238. In regard to phthisis and diseases of the respiratory organs, medical men compare very favourably with other classes.

The remarkably greater fatality from epidemic diseases, save small-pox, from which medical men protect themselves by vaccination, but not to the extent that they might—will correct the public impression that they have charmed lives and hidden means of resisting infectious disease. They are like soldiers: their profession involves high risks, with a certain amount of unwise contempt for them, bred of familiarity. Much of the other excessive mortality of medical men is only a natural consequence of the arduous and anxious calling which they follow, in which competition is great and increasing, and in which sleep and food, that come to all else with regularity, come to them brokenly and irregularly. However, to be forearmed is to be forewarned, and we cannot doubt that in the clear light of Dr. OGLE'S information medical men will set themselves to counteract the causes of their ill-health. The glory of the medical profession is that it promotes the health of others rather than that of its own members. But example is better than precept, and we may do yet more good by exemplifying the powers of medicine in our security as we do in the case of small-pox. The part of Dr. OGLE'S paper that needs the most serious consideration is that which seems to show the greater liability of medical men to gout, liver disease, urinary disease, &c. This is largely to be explained by the irregularities of medical life and feeding, and the tendency of a busy and worried medical man to put himself off with a hasty glass of wine or beer instead of a regular meal. Dr. PARKES used to measure his alcohol in a minim glass. This is the lesson of medical science in regard to alcohol, and to no man is it of more importance than to those who have so many more risks and so few more comforts than other men.

GENERALISATION is the aim of pathological inquiry; but the attempt to attain it has too often been the source of much error and confusion. Nor is this to be wondered at,

Digitized by Google

seeing how incomplete is our knowledge upon many essential points of pathological investigation. So far as generalisation is the outcome of a collation of well-observed facts, and in proportion as it comes to be less the offspring of theory, is it likely to be sound and just. Too often, however, has theory or *a priori* conception been suffered to form the basis of a general inference, and the inevitable overthrow of the superstructure occurs in progress of time. There could hardly be selected a better instance of pathological generalisation than the doctrine of "arterio-capillary fibrosis" which was propounded by Sir W. GULL and Dr. SUTTON more than ten years ago. It had much support in observed facts, both clinical and pathological, and was rendered even more attractive by the wide-reaching speculation which sought to place it almost amongst the normal physiological changes of the organism. In spite of this, the doctrine has failed to be received with that universal assent which, were it really the expression of a law of nature, it must have commanded. Probably this is in some measure owing to the theory upon which it was based, and not so much to the actual connexion between the vascular lesions and fibroid changes in organs. A similar conception, but one approached from a different point of view, has been during the past few years a favourite theme of M. HIPPOLYTE MARTIN, to whose article on the subject in the current number of the *Revue de Médecine* it may be useful to direct attention.

Briefly M. MARTIN's thesis is this: that sclerosis and allied changes in tissues and organs are not inflammatory nor due to any primary lesion of the tissue itself, but constitute a passive process, a dystrophic change, depending upon the progressive obliteration of the smallest nutrient vessels by endarteritis. Many diseases in which sclerosis plays a part are induced by conditions which would favour the production of a progressive obliterating arteritis. Such poisons as alcohol and lead, for example, may rationally be supposed to exert their initial effect upon the delicate lining of the vessels traversed by the blood they contaminate; and few will question that the coarser arterial lesions of syphilis are evoked in a similar way. But the etiology of sclerosis is not by any means limited to such gross agencies, and in order to explain the far wider occurrence of fibroid changes than can be thus accounted for, M. MARTIN is compelled to invoke the agency of trophic nerves and to imagine that, deprived of their influence, the arterial endothelium swells and proliferates. To do this he has first of all to prove the existence of a tropho-neurosis, and thus meets at the outset with difficulties which may prove insuperable to the acceptance of his generalisation. At the same time, whether by trophic agency or not, the fact remains that in all the conditions he enumerates the smaller arteries are to be found obliterated in the very earliest stages of the degenerative change. Thus, taking atheroma of the aorta as an instance of what he terms a "dystrophy," he has detected obliteration of vasa vasorum in the affected area even in those cases where minute atheromatous patches are met with in childhood. The effect of the failure of nutrition to the wall is to cause a fatty degeneration of the higher tissues—e.g., the muscular fibres—and a compensatory increase of fibrous tissue. This is in one sense a reversion to the old doctrine of atheroma, for it obviously does not regard it as an inflammatory condition. In support of this view M. MARTIN avers that the smaller arteries which escape atheromatous changes are just those which have no vasa vasorum, but, like the latter, they are disposed to become the seat of obliterative endarteritis, and thereby bring about sclerosis of the organs they supply Applying this doctrine all round, he ascribes the sclerotic changes of the cardiac valves and in the cardiac muscle itself to obliterative inflammation of the intima of their nutrient vessels. In the kidney the same process plays naturally a great part in the production of these changes, which when advanced form the granular or cirrhotic kidney; but he finds it impossible to ascribe more than the initial stages of this disease to pure denutrition. Consequently, to explain the contraction that ensues, and the extent to which fibrous tissue replaces the wasted and shrivelled tubules, the intervention of inflammation is invoked; but not as an esential part of the process, for in his doctrine renal cirrhosis may be wholly free from interstitial nephritis, being solely and simply the outcome of defective blood-supply. In this paper he touches but lightly upon sclerosis of the nerve-centres, having previously discussed its origin in more detail; but it is plain that he regards even posterior spinal sclerosis as produced by the obliteration of nutrient arteries, and not as primarily a disease of the nerve tubules. The change they undergo is, as in the parenchyma of other organs, purely a passive regressive change. The same chain of events, primary progressive obliterating endarteritis, secondary degeneration of higher tissues with fibroid substitution, is he holds, to be found, or at any rate to be expected, in sclerosis of the lungs, liver, spleen, alimentary tract, skin and indeed in all parts of the body. In point of fact, this widespread lesion of increase of the fibrous tissue of an organ, with destruction of the functional cells, owns but one immediate cause; and this is to be found, to use Sir W. GULL'S expression, within the vascular area. If inflammation intervene, it only hastens the process already initiated by the gradual diminution of the blood-supply due to a process which is almost physiological.

It will be remembered that Sir W. GULL and Dr. SUTTON regarded "arterio-capillary fibrosis" as a condition rather of natural senility than as a specially morbid change. So here we find M. MARTIN expressing the belief that "progressive obliterative endarteritis" is the natural process that eventuates in the hardened organs of old age. On either view, the process only becomes pathological when it anticipates the advance of years or predominates in one part of the body out of due proportion. There are individual proclivities to early degeneration, and there are agencies which promote the advance of degenerative lesions. The whole matter, on M. MARTIN'S hypothesis, is referred one step further back; it requires, for instance, that we should regard atheromatous change, not as being a primary inflammatory or degenerative lesion, but as being itself dependent upon a change in the ultimate ramifications of arteries concerned in maintaining the nutrition of the affected bloodvessel. On his doctrine, then, the cardiac hypertrophy of Bright's disease is not to be regarded as dependent on interstitial nephritis, nor arterial atheroma as solely respon-

Digitized by Google

sible for the visceral disease that accompanies it, but rather that one and all are due to a "progressive pathogenic process which advances slowly from infancy to age."

THE British National Society for Aid to the Sick and Wounded in War during the Egyptian Campaign in 1884-85 has just issued a report of its operations, together with a statement of receipts and expenditure, and correspondence. The report is short and very laudatory, and thanks are profusely tendered to all who were concerned in the work undertaken by the Society. We observe with much satisfaction that the committee have taken advantage of the occasion to remove a very unpleasant feeling created by one of their previous reports, that there had been neglect on the part of the Army Medical authorities in not having made adequate provision for the sick and wounded: "They desire to take this opportunity of correcting an error which unintentionally appeared in a paragraph of a previous report, by which it might possibly be inferred that the Society claimed to be doing work on the Nile, by means of their steam launch and dahabeah, which the Army Medical Department could not of itself have carried out. Any such inference was unintentional, and would have been unjustified. With the British Army sent out to Egypt the Government provided complete supplies of medical appliances, comforts, and transport for the sick and wounded, and there was consequently not so large a scope for the operations of the National Aid Society as has hitherto existed when working with Continental armies." The *amende* appears to us, however, to confirm the doubts we have on a previous occasion expressed (*vide* THE LANCET, May 2nd, 1885) whether the expenditure of a sum close upon £20,000 was justifiable, not to supplement an already efficient service, but to provide luxuries which were by no means required for the class of persons to whom they were sent. We fully appreciate the expression of sympathy on the part of those who took an active interest in providing the funds and in carrying out the requisite service; but we think their energies were expended in a wrong direction, and that a more judicious and fully as sympathetic a course would have been followed had a large portion of the money been employed in relieving the wants and alleviating the sufferings of the women and children left at home, instead of being devoted to providing what may fairly be deemed luxuries for the troops in Egypt. The Society seems to have purchased a small steam launch and a stern-wheel steamer for the transport of their stores and to assist in bringing down invalids. But apparently the latter service was already sufficiently provided for by the Government. They also sent out trained nurses, who did very good service in the hospitals; and if we except the provision of newspapers, this seems really to have been almost the only useful work done by the Society. Soda water and effervescing drinks figure largely among the stores sent out by the Committee, and twenty-seven dozen pints of eau-de-Cologne and 359 dozen pots of jam appear also in the list.

The appendix to the report fills seventy pages, and consists, to a considerable extent, of reports of a very roseate hue, from Major J. S. YOUNG, one of the Commissioners of the Society, to H.R.H. the Princess of WALES and to Sir R. LOYD-LINDSAY, and from Mr. V. B. KENNETT-BARRINGTON, the other Commissioner, to Sir R. LOYD-LINDSAY. But while reading these reports we cannot forget that Dr. W. H. J. BROWN, one of the medical men sent out by the Society, who is spoken of very favourably by Major YOUNG, has given a different account of the manner in which affairs were conducted, or how little was being done at home for the women and children while the funds of the Society were being thus expended abroad.

It is satisfactory to learn from the report that throughout the campaign most amicable relations subsisted between the army and navy medical officers and the civilians sent out by the Society. On the subject of the arrangements made by the former, Dr. SQUIRE thus writes: "As a civilian who had exceptional opportunities for observing the medical arrangements of the force, I cannot resist mentioning the admirable nature of the preparations made. I found a hospital, almost in the desert, arranged and provided in a manner which would have done credit to a hospital at home, while nothing in the way of medical and surgical necessaries for the sick was wanting." Surely this corroborates our view of the supererogatory nature of a great portion of the service rendered by the Society. It is painful to us to speak of it in such terms, but we do so in the hope that its exertions on any future occasion may be turned in a more profitable direction.

IN the two cases of alleged criminal abortion recently investigated by the coroner for Central Middlesex, and subsequently at the police-court and the Old Bailey, there were several points of medico-legal interest and importance. Our remarks, however, will be limited to the consideration of the question as to how far the corpus luteum may be relied upon as furnishing evidence of recent pregnancy. It may be taken for granted that the assertion made by HALLER that "the corpus luteum is the effect of pregnancy alone" is demonstrably contrary to fact. The researches and expositions of Dr. ARTHUR FARRE and other distinguished observers have shown that, whether the ovum is fecundated or not, the corresponding Graafian follicle presents after its rupture certain determinate characters, which collectively negative the conclusion arrived at by HALLER. Again, the terms "true" and "false," as applied to the corpora lutea of ovulation and pregnancy respectively, are based upon unscientific data; for the initial stages of development in both instances are essentially the same. Responding to the excitation of the generative organs incidental to pregnancy, the lining membrane of the Graafian follicle takes on active change. The plicated lining becomes thicker, it assumes a deeper hue, and it vascularises and becomes firmer in consistence; or, to quote the words of an eminent writer, the construction of the corpus luteum of pregnancy is "conducted upon a larger scale and with a greater abundance of materials" than is obtained in the absence of impregnation. The plication above referred to is asserted by some to depend on the contraction of the external coat of the ovisac, but this can scarcely be an adequate explanation, for it fails to account for the increase in size which the corpus luteum undergoes up to about the fourth month of gestation. The history of the corpus luteum of ovulation is played out in about two months, whilst that of pregnancy extends over a period of

Digitized by Google

thirteen or fourteen months. COSTE, in his dissertation, says the corpus luteum of pregnancy becomes as large as the ovary itself—a somewhat exaggerated statement, whether regarded in its relation to any individual case or as a general indication of what habitually obtains. It is curious how widely at variance are our standard text-books on medical jurisprudence in the estimation of the amount of reliance that can be safely put on the evidence furnished by an examination of the ovaries *quoad* the existence of pregnancy. In the last edition of TAYLOR'S standard work the reader will find that the author, apparently rather from an analysis of the conflicting testimony of others than from direct investigations of his own, shows but little tendency to adopt the positive views entertained by GUY in his "Manual of Forensic Medicine." The latter author would lead one to believe that the corpus luteum of pregnancy is not only different from the corpus luteum of ovulation, but that it is sufficiently so for the practical purposes of enabling the medical jurist to form a trustworthy opinion in support or refutation of the contention of recent abortion—an opinion, in fact, which he would not hesitate to express on oath in a criminal court. It is not given in so many words, it is true, but the general tenour of the writer's views is such as to leave no doubt on the mind of one not specially conversant with the subject. We have no hesitation in saying that in certain cases the development of the corpus luteum is such as to warrant the conclusion that there has been a recent pregnancy—take, e.g., what was found in the right ovary on examination of the body of the girl CLIFFORD who died at TURNBULL'S house. The medical men engaged by the Treasury reported that it contained a corpus luteum more than five-eighths of an inch in diameter, of a deep orange colour, contrasting strongly with the reddish-grey tint of the ovarian parenchyma. In the absence of chronic disease of the pelvic organs, and of ascertainable signs of other sources of irritation calculated to give rise to unusual nervous and vascular disturbance in the ovary, it is but reasonable to subscribe to the judgment formed and formulated in this case. On the other hand, it must be allowed that there may be circumstances—notably, when the ovarian stroma and capsule are indurated from protracted inflammation—capable of preventing the normal development of the corpus luteum of pregnancy. In the case of the woman BURTON, in whom it was alleged TURNBULL was guilty of having illegally procured abortion, there could be no shadow of doubt that a miscarriage had happened, for, in addition to the enlargement of the womb, a considerable portion of the placenta was found attached to the uterine wall; and yet the corpus luteum observed in the left ovary, although it presented a corrugated outline, was small and of a dull grey colour, features not inconsistent with the supposition that it might have been merely the consequence of ovulation without impregnation. The capsule of the ovary, however, was so thick and dense as to effectually prevent its expanding to more than a very limited extent. The views originally held—(1) that the corpus luteum was proof positive of pregnancy, and (2) that the so-called false corpus luteum of ovulation differed in nature from the true corpus luteum of pregnancy—serve to explain the irreconcilable statements met with in the various text-books on obstetrics and legal medicine. Descriptions have been handed down from author to author either in their original integrity, or with incomplete and misleading corrections, so as to obscure the subject in too many instances by equivocal expressions and false deductions. It is, on the one hand, matter of regret that a possible valuable source of evidence should be held in disfavour, and, we may say, disrepute; and, on the other, that it might, inadvertently no doubt, be resorted to unconditionally, and so tend to the discredit of medical science and the prevention of the administration of justice. The entire question deserves and requires full investigation, and to this end it is desirable that a number of observations should be made and recorded of the exact conditions of the corpus luteum, in respect to its relation to ovulation and pregnancy. The Obstetrical Society would do well to initiate the movement, and carry it out under its direction and supervision.

THE question of the digestion of albumen in the intestine has been the subject of many experiments. By some, as by THIRY, it has been held that the intestinal juice possessed almost as much activity as that of the stomach itself; whilst others, as MASTOFF, denied its efficacy as a digestive agent altogether. The point has again been investigated by WENZ, who has given the results of a long series of researches in the *Zeitschrift für Biologie*. Many difficulties surround the inquiry. It is difficult to obtain perfectly normal intestinal juice. If a portion of the small intestine be isolated, as in the method suggested by THIRY, and the fluid which collects in the loop be experimented with, it is easy to object that the natural secretion is seriously modified by the operation; and if, on the other hand, proteid substances are injected into an artificially produced fistula, it is difficult to entirely prevent the intermixture of the gastric and pancreatic secretions.

WENZ, from a review of the work of previous observers, came to the conclusion that no satisfactory results could be obtained unless some means were devised by which the intestinal juice could be obtained free from foreign enzymes, and indeed from any organised ferment, whilst the observer should be sufficiently instructed to be able to recognise and to isolate the new substances which might be expected to result from the operation of the enzymes produced by the intestinal mucous membrane. Proceeding on this basis, and upon the fact generally admitted by chemists, that all hitherto known enzymes can be extracted and isolated by appropriate treatment with water, very dilute acids, alkalies, and glycerine, without any loss or impairment of their power of decomposing albumen, he first thoroughly cleansed an unopened tract of intestine of all pepsine and trypsine ferments, that strongly adhere to the mucous membrane, by washing it for a long time with water, till this fluid passed through perfectly clear. The intestine was then opened upon a glass plate, and the mucous membrane detached and subjected to somewhat complicated treatment, ending in the obtainment of a glycerine extract. In two other experiments which were made for him by Professor KÜHNE, intestinal fistulæ on THIRY'S plan—that is, by the isolation of a loop of ileum by means of a ligature and the establishment of an external opening—were made in dogs, and the intestine included in the ligatures was daily washed out for six days with normal saline solution. The maximum

Digitized by Google

amount of secretion obtained in this way from a loop thirty centimetres (about one foot) in length was 1 to 1·5 cubic centimetres; on mechanical irritation it was transparent and yellowish, possessed invariably an alkaline reaction, became slightly cloudy on neutralisation, and after precipitation with ammonium sulphate contained no peptone. To prevent putrefaction in the experiments on digestion of albumen, a small portion of thymol or a drop or two of a 25 per cent. of an alcoholic solution of thymol was added. The substances which were looked for after the action of the juice on proteids were those which have been described by KÜHNE and CHITTENDEN under the names of deutero-albumose, proto-albumose, hetero-albumose, and dys-albumose, as well as those termed anti-albumose and anti-albumid. Now, all these substances are precipitable by ammonium sulphate, but peptone is not, and an excellent means of separating them is thus afforded. WENZ, after satisfying himself on this point by many experiments, proceeded to examine the influence of acid, neutral, and alkaline extracts of the mucous membrane of the small intestine, with the result that such extracts possessed, when free from trypsin, little or no power of peptonising the proteids. The experiments on the dogs with intestinal fistulæ were not very satisfactory, owing to the serious effects upon their general health of the administration of pilocarpine, which had been given to them with a view of clearing their alimentary canal, but so far as they went they also showed that little peptonising power was possessed by the juice. These experiments, which appear to have been carefully performed by a competent observer under the supervision of so excellent a chemist as KÜHNE, are therefore in opposition to those of THIRY, LEUBE, DOBROSLAWIN, KROLOW, GRÜTZNER, GARLAND, VILLA, and others, some of whom found that fibrine appeared to be converted into peptones in acid and others in alkaline mixtures, and are in accordance with the observations of CZERNY and LATSCHENBERGER, MARKWALD and DÉMANT,—thus adding one more to the many vexed questions in modern physiology.

Annotations.

"Ne quid nimis."

SORE-THROAT AT SANDRINGHAM.

IF a triangle is drawn, having a base stretching from King's Lynn to Walsingham, and the apex at Docking, it will include that portion of Norfolk mainly embraced by the three registration districts named after these respective places. The estate of Sandringham, the seat of the Prince of Wales, including about 7000 acres, and consisting of several parishes, occupies a portion of this area. It consists of a large portion of very wild, unreclaimed sporting land, and some rich meadow and pasture, and salt water marshes. Sore-throat of a diphtheritic character, from which the Princess and, we believe, members of the household have suffered, appears to have a natural home in this locality. For example, statistics gathered from the Registrar-General's returns show that the death-rate from diphtheria in the Docking and Walsingham districts bear the proportion of [illegible] to 0·9 in the Norwich registration district and 0·3 in other districts of the same county. The death-rate from diphtheria in this portion of Norfolk is in excess of the death-rate from the same diseases in St. Giles', Shoreditch, Bethnal-green, Whitechapel, or St. George's-in-the-East, which are among the poorest and least sanitary districts of London. Yet here is the home of the Heir Apparent and his family, purchased by the advice of the Government at a cost of £220,000. We cannot suppose that in the house at Sandringham insanitary conditions have been permitted to prevail, for it was here the Prince was so seriously ill from typhoid, by which attention should have been forcibly directed to the sanitation of Royal residences. The Prince Consort lost his life at Windsor, though it is suspected he contracted the disease at Sandhurst. The Prince of Wales nearly lost his life at Sandringham, though it is not quite clear where and how he contracted the fever. The Duchess of Connaught's life was in danger in the newly-erected residence in Bagshot-park; and at last the Princess of Wales has been subjected to risks, and with her in all probability others of the family and the many distinguished visitors who have been at Sandringham since Christmas. Yet all this danger and inconvenience is removable by well-understood and simple methods. Any gentleman would regard it as a paramount duty to his family to select his home in a district where sanitary statistics were satisfactory, or he would set about at once to remedy the defects as far as practicable. We suspect the undrained marsh lands in this portion of Norfolk, as elsewhere, to be at the bottom of this diphtheritic tendency, and till they are drained diphtheria will prevail. The Prince of Wales can scarcely, with his many duties, be expected either to understand or attend to such matters, but his advisers should. Had the Princess died, what would have been the verdict of the people?

INFECTIOUS HOSPITALS IN RURAL DISTRICTS.

DR. WOODFORDE'S annual report for 1884 on the combined sanitary districts of Berkshire reaches us at a date when public interest in the sanitary circumstances of the district for the period in question is necessarily to a great extent a matter of the past. One or two points of general interest are, however, raised in the report. In the Abingdon rural district Dr. Woodforde has had to consider the advisability or otherwise of providing a hospital for the isolation of cases of infectious disease, and he has felt that the practical difficulties which would have to be overcome are such that his advice has been that the spread of infection could be more effectually controlled by obtaining the assistance of thoroughly trained nurses to deal with all known cases of infection occurring in a given locality than by hospital provision. Besides a number of difficulties, such as the concealment of first attacks, which apply more or less to all districts in the United Kingdom where compulsory notification is not in force, the fact that scarlet fever is a disease which would largely have to be dealt with, and that the sufferers would in consequence be mostly young children, is adverted to. As to this we would point out that, according to the official report on Hospitals for Infectious Diseases, it was found that this drawback is more imaginary than real, and that out of a total of 4758 admissions at all ages into hospitals provided by sanitary authorities, no less than 2673, or 56 per cent., varied in age from a few months to ten years; and that in one rural district 81 per cent. (nearly all being scarlet fever cases) had been admitted at that age out of a total of 220 patients at all ages. One great difficulty as to the alternative system advocated is that the provision of nurses, except in hospitals, is not authorised under the Public Health Act. Another suggestion is, however, contained in the report—namely, the removal of the healthy members of a family to an empty cottage with a view to their being kept under supervision for a period equal to the incubation of the disease, and the retention of the infected

Digitized by Google

cottage as a temporary hospital for the first patient attacked, and for any that may follow. This provision of a temporary hospital would appear to be clearly within the powers of the authority, who would only have to secure the assent of the landlord and tenant to the proposal; but how the payment for the other cottage could be legally made we are by no means clear, and what the authority would do if the hitherto healthy people were to refuse to submit to the suggested "supervision," which rather savours of quarantine, we do not know. Doubtless, however, there are districts in which, under judicious management, much useful work in the direction of the isolation of infectious diseases can be done which may not come strictly within the letter of the law; but it is certain that these schemes cannot be regarded as universally applicable to sparsely populated and rural districts. The difficulty of providing special buildings as hospitals in such districts is, in some important respects, a real one; but there are many localities where the authorities would not object to erect the simple four-bedded hospital of which plans were last year issued by the Local Government Board, whereas they might with reason object to the provision of means of isolation on a larger or more expensive scale.

ANTIPYRIN AND CALOMEL COMPARED IN PNEUMONIA.

THE *St. Petersburg Weekly Clinical Gazette* publishes some observations which have been made by Dr. Posadski, under the direction of Prof. S. P. Botkin, on the comparative results of the antipyrin and calomel treatments in croupous pneumonia. He thus treated a group of twenty-five cases with antipyrin alone, giving from half a gramme to two grammes (seven and a half to thirty grains) for a dose, and one to eight grammes (fifteen grains to two drachms) per diem. A second group of twenty-three cases, as similar as possible to those of the first group, was treated with calomel in doses of one-eighth of a grain four times a day. The average age of the patients in the first group was twenty-seven years and a half, and that of those in the second twenty-five years and a half. Those treated with antipyrin retained their full consciousness, but in the course of two or three days failed greatly in strength, the heart's action becoming exceedingly weak. They suffered from cough, and with difficulty expectorated a small quantity of slightly-tinged sputum. After the first few doses there was a fall in the temperature, but not of a permanent character; sometimes, indeed, there was no fall at all, and when there was, notwithstanding the continuance of the drug, a rise followed. The crisis took place with a fall of temperature on the average on the seventh day of the disease, the mean number of days of fever being 8·1, but the local physical signs lasted 13·5 days. Complications occurred in nearly all the cases, sometimes being of a serious nature, collapse even being noted. In the urine there was nearly always albumen in considerable quantity, also antipyrin. The fall in weight averaged 20·34 zolotniks (about twenty-seven ounces), which was less than the mean fall of the patients treated with calomel, but the latter recovered their weight more rapidly during convalescence. When the doses of antipyrin were frequent, vomiting was often induced, and in two cases an antipyrin rash made its appearance. Those treated with calomel frequently presented a typhoid condition, and in some cases there was delirium. They were not much distressed by cough, the sputum was expectorated easily and in considerable quantity, and they did not suffer from sweats. The temperature rose high. The mean duration of the fever before the critical fall was 7·1 days, which was generally accompanied by drenching perspiration. The local physical signs lasted on the average 9 days (against 13·5 in the other group). There was rarely albumen in the urine, and when it existed there were only traces. Complications were infrequent. The general conclusion arrived at was that antipyrin, in spite of its power of reducing fever, has no beneficial effect on the course or result of the disease.

THE CERTIFICATION OF LUNATICS.

ATTENTION is again directed very painfully to the fact that there may be insuperable difficulty in legally certifying the unsoundness of mind of a person who is actually in peril of committing a deed of violence for which he or she will afterwards be held irresponsible on the ground of insanity. Beyond question this is a most anomalous state of matters, full of danger to the public, and yet it arises inevitably out of the most unsatisfactory state of the laws relating to the certification of lunatics. If only the power existed to place persons who are obviously—perhaps even self-consciously—on the borderland of insanity under protection and treatment, with their own consent, without branding them as lunatics, few of the distressing occurrences which now harass the public mind and too often involve the loss of life, as in a recent deplorable case now *sub judice*, would arise. It is unjustifiable to blame medical men for what an uncertifiable lunatic may do. Unless there be express evidence of insanity in act, or of the existence of some delusion, the form of certificate provided by the Acts in force cannot be filled up, and the issue must be left to the chapter of accidents. Coroners are far too ready to blame medical men when anything goes amiss. They seem to think somebody must be to blame, and practitioners of medicine are regarded as fair game. Against the undiscriminating condemnations thus heaped on the heads of members of the medical profession we protest. The existing state of the law affords an abundant explanation of the scandals which from time to time arise in connexion with the certification or non-certification of lunatics. Until the Legislature can find a convenient time for reform there will be no means of preventing these occurrences.

WHAT CONSTITUTES A NUISANCE?

IT is certainly curious how certain localities and people cling to nuisances, however gross, on the ground that they have been long accustomed to them. In the Forfar Police-court proceedings were taken against an occupier for allowing a nuisance in close proximity to a draper's work-room where young women are employed, this nuisance being, it was contended, injurious to health. The alleged nuisance was in a court adjoining the workshop, the court measuring twelve feet in breadth. In this confined area, on to which a window of the draper's premises opened, were four pigs, a privy, and a lot of manure, and this although some four cartloads had already been removed. But plenty of people were found to declare that it was no nuisance at all, and one witness maintained this view as the result of twenty-five years' experience of it. Although we are fast getting rid of such abominations as the storing up of many tons of pig and other dung in courts, yet even down south we still meet with similar opinions. But they do not, as a rule, emanate from, and receive the support of, medical men, and we can only hope that the practitioner whose evidence is quoted in the *Forfar Herald* has been erroneously reported. He is alleged to have declared the state of affairs to be no real nuisance; indeed, whereas pigs are proverbially the producers of such foulness as to call for special bye-laws against such animals, he thinks that pigs keep down the smell because they trample down the manure, and he is of opinion that "six loads" of such stuff can be kept in the

Digitized by Google

court without injury to health. It was also shown that a drain on the draper's premises might have contributed to the nuisance. Judgment was reserved when the account reached us. We trust it will not be based on such retrograde views as we have referred to, and we commend to the sanitary authority the bye-laws issued by the English Local Government Board as to the prevention of nuisances from the keeping of animals as annotated by Messrs. Knight and Co.

EMBOLISM AND CHOREA.

IN the first number of THE LANCET of the present year we published an article on the relations of Embolism and Chorea, by Dr. Howship Dickinson. Anyone who is conversant with the literature of chorea—using the term in its widest sense, as including every phenomenon that has ever received the name, and their number is legion—will grant without hesitation that there never was a problem that presented more diversity of aspect, more change of opinion, and less likelihood of arriving at a satisfactory solution. Mr. A. H. Benson has reported in the current number of the *Ophthalmic Review* a case of partial embolism of the inferior division of the central artery of the retina associated with repeated previous attacks of chorea. The patient was a man, aged twenty-one, who had had rheumatic fever in 1881, chorea in 1882, again in 1883, and once again in 1884. The retinal embolism was, however, unaccompanied by symptoms in other parts of the nervous system. Mr. Swanzy in 1875 recorded the case of a girl, aged ten, who developed chorea, and at the same time facial paralysis and embolism of the left central retinal artery. In neither of these cases was there any evidence of heart disease. The occurrence of such associated phenomena lends considerable countenance to the embolic theory of "chorea," but cannot be regarded as conveying anything in the nature of proof.

THE DENTISTS IRATE.

THE organs of dentistry are again very angry with us because we have dared to say anything about the teeth. They feel much hurt with the remarks we recently made about Hunter's views of decay of the teeth, and our reference incidentally concerning his opinion as to the legitimate line of demarcation between general surgery and dentistry. We can assure the specialty that we had not the slightest intention of wounding their feelings or of trenching on the province they have so cleverly monopolised. Our observations were entirely made for the medical profession; and so solicitous were we to avoid the use of irritating language that, in quoting John Hunter, we made a garbled quotation, omitting the words, "The diseases which may arise in consequence of those of the teeth are various, such as abscesses, carious bones, &c., many of which, although proceeding originally from the teeth, are more the object of the surgeon than of the dentist, who will find himself as much at a loss in such cases as if the abscess or carious bone were in the leg, or any distant part. All the diseases of the teeth, which are common to them with the other parts of the body, should be put under the management of the physician or surgeon; but those which are peculiar to the teeth and their connections belong properly to the dentist." In point of fact, our claim was a smaller one than Hunter's; and we thought of being complimented for our modesty, instead of being rated for the mingled audacity and ignorance of our proposals. Let this pass. It is further objected that we could not have read Hunter's work because when stating his view of the nature and causes of decay we said, "It is not due to external or accidental causes." As a matter of fact we had read Hunter's work, and moreover it lay before us when we wrote. His precise words are these: "It does not arise from any external injury, or from menstrua which have a power of dissolving part of a tooth, for anything of that kind could not act so partially; and we can observe in those teeth where the disease has not gone deep that from the black speck externally there is a gradual decay or alteration leading into the cavity, and being fainter and fainter. We may therefore reasonably suppose that it is a disease arising originally in the tooth itself," &c. In the reference we ventured to make to the subject of "acids," we spoke of ordinary acid foods and beverages, not of acid medicines. In regard to the latter we quite agree with our dental contemporaries. We had not the least notion of asserting the finality of Hunter's opinions, still less of setting them up as against the opinions of more recent authorities. Our sole object was to direct the attention of members of the medical profession, as distinguished from dentists, to the fact that decay of the teeth is a matter which ought to be studied from the medical standpoint. In the treatise from which we quote Hunter was very careful to observe what he believed to be the limits of the specialty of dentistry. Thus in writing for dentists he said, "I shall purposely avoid entering into common surgery; not to lead the dentist beyond his depth, or to matters of which it is to be supposed he has not acquired a competent knowledge." Our remarks were, as we have said, for physicians and surgeons, not dentists.

SYPHILIS, ACQUIRED AND INHERITED.

THE Lettsomian Lectures on "Some Moot Points in the Natural History of Syphilis," delivered at the Medical Society by Mr. Hutchinson, raise questions of great social importance. The acceptance as an established fact that apparently pure vaccine lymph from an infant inheriting syphilis can communicate syphilis to a non-syphilitic individual through vaccination naturally gives rise to some very grave problems. If, as Mr. Hutchinson contends, secondary symptoms may follow chancroid ulceration as well as true chancre, and further that it is impossible to say that an apparently simple gonorrhœa may not have a syphilitic urethral ulceration blended with it, then the area of the natural history of syphilis becomes very much extended. The primary sore, whether chancroid or true chancre, is as a rule subjected to specific treatment, and the liability to secondary constitutional mischief is reduced to a minimum. But it is quite different with syphilitic urethral ulceration blended with gonorrhœa. This is subjected to the ordinary treatment of gonorrhœa, and the syphilitic nature is only suspected when in due course secondary symptoms present themselves. This would appear to call for a very minute examination of every case of gonorrhœa, with a view to determine its syphilitic or non-syphilitic character. Other points of equal interest arise out of Mr. Hutchinson's lectures. It is beyond a doubt that the offspring of a syphilitic parent may be free from all apparent syphilitic inheritance, and, on the other hand, the offspring may present features of a syphilitic taint inherited from a parent in whom all symptoms of the syphilitic taint are in abeyance. When, then, is sanction to marry justifiable in the case of one who has suffered and apparently recovered from syphilis? It is within the experience of most medical men to have seen cases of newly married couples in which the wife as soon as she becomes pregnant presents unmistakable signs of secondary symptoms. The husband, however, may have been unsuspicious of having a syphilitic taint. Many of the skin eruptions of married women have their origin in this taint, unconsciously acquired and unconsciously communicated. Many a puny child owes the blight in its nature to an inherited taint. The disposition to sore throat at every little fluctuation in health is often an indication of this taint. The question how best to reduce

Digitized by Google

these evils to a minimum has not yet been fully answered. One point especially has never been adequately explained—that is, why the syphilitic taint, whether acquired or inherited, should have such a predilection for the skin, mucous membrane, and especially the throat,—for the latter is as reliable an index of the disease as the barometer is of the weather. The non-mercurial treatment has been fairly tried and found wanting in cases of true syphilitic infection. Mercury in small doses continued over a long period of time, supplemented by the local application of the same remedy, and followed by an equally lengthened course of potassium iodide, beginning with ordinary doses and gradually increasing to half-drachm doses two or even three times a day, will subjugate the virus more than will any other remedies. But these may need repeating on the least re-development of symptoms, whether these be in the form of the graver internal complications, or skin eruption, ulceration of mucous membrane, or sore-throat.

THE VENTILATION OF SEWERS.

THE grievously vexed question of sewer ventilation is again pressing for an answer. There never will or can, we are convinced, be a final settlement of this issue until the absurd theories and devices of those who confound the behaviour of gas and vapour with that of water, and whose judgment is vitiated by other fallacies, have been utterly cast aside and abandoned. The particularly ridiculous notion that sewers can be ventilated by an arrangement which amounts to the construction of an inverted syphon—the pure air to be drawn at the mouth of a low-level pipe, and the foul air ejected at the open mouth of a high-level pipe—is probably one of the most mischievous and obstructive of prevailing misconceptions. As a matter of fact, there is only *one* way of effectually ventilating close drains and sewers, and that happily is an easy one. Pipes, which ought to be not less than four inches in diameter, as perpendicular as possible, and protected by a cowl at the summit, should be carried up from the drain or sewer to a point well above the level of the roofs of adjacent houses, and placed far away from chimneys. By means of these pipes the sewers may be properly ventilated. Much may be accomplished by any householder who has the spirit to place two or more ventilating-pipes of the construction indicated on his own premises. Sooner or later low-level or "surface" ventilators will be prohibited. We believe that to the agency of such apparatus, as disseminators of sewer gas, is to be ascribed much of the sickness which prevails in many localities. The effluvia rising from too many of these surface-gratings and low-level ventilating-pipes afford conclusive evidence of their dangerous character.

MITRAL DISEASE.

THE perennial interest that hangs around the study of diseases of the valves of the heart is strong testimony of the lack of definite knowledge concerning the physical signs of valvular lesions. Two papers in the first number of the *International Journal of the Medical Sciences*, which is also the 181st number of the new series of the renowned American journal, continue the interest and develop new phases in the study of mitral lesions. Dr. Austin Flint treats of mitral cardiac murmurs, but Dr. Broadbent is concerned only with mitral stenosis. There are four mitral murmurs according to the American author: (1) The systolic regurgitant; (2) the systolic intraventricular not due to regurgitation; (3) the presystolic; (4) the diastolic. Each of these four murmurs has distinctive characters; there may be a combination of any number of them. Hayden's nomenclature of post-diastolic and post-systolic appears to Dr. Flint an unnecessary refinement: in this view, regarded clinically, we are disposed to agree, but think that the refinement is not excessive when viewed in the light of differentiation, as an aid to the promotion of a scientific knowledge of murmurs. Dr. Broadbent considers that mitral stenosis is on many grounds the most interesting valvular affection of the heart. Its frequency and dangerousness—being second in peril only to aortic incompetence, and indeed the more serious of the two in early life—impart to it a very practical interest. The circumstance that it presents far greater difficulties in diagnosis than any other disease of the valves has been the chief reason for Dr. Broadbent's paper. It was the last of the valvular lesions to be associated with distinctive physical signs, and even now its existence is entirely overlooked by physicians, and it is not unfrequently confounded with the less serious form of mitral disease. The difficulty is largely to be accounted for by the fact that the physical signs are extremely varied, sometimes requiring careful prolonged examination by a skilled ear before a diagnosis can be made, and at other times so marked that the youngest student may diagnose with certainty. An attempt to elucidate the significance and appraise the diagnostic and prognostic importance of the physical signs is the chief object of the paper.

THE NEUROLOGICAL SOCIETY OF LONDON.

WE have to announce the birth of a new association—the Neurological Society of London. Informal meetings have been held, and a committee appointed to frame a constitution. A recent meeting has sanctioned the laws thus framed; and a council has been elected, with Dr. Hughlings Jackson as president, and Dr. S. Wilks and Sir J. Crichton Browne as vice-presidents. Dr. Bristowe is to be the treasurer. Drs. Bastian, Broadbent, Bucknill, Buzzard, Ferrier, and Savage, and Messrs. Galton, Hutchinson, Romanes, and Professor Schäfer are also members of council. Dr. Hughes Bennett and Dr. de Watteville are acting as hon. secretaries. The scope of the Society is of the widest, including not only the physiology and pathology of the nervous system, but also that section of neurology which is concerned with psychology, both normal and morbid. The Society chiefly owes its existence to the enthusiasm of the acting editor of *Brain*, Dr. de Watteville.

THE THREE TOWNS' MEDICAL INSTITUTION.

A GOOD deal of correspondence between the medical officer of this institution and the executive has appeared in the local papers, and the general result is to confirm our oft-expressed opinion that these institutions aim at getting out of their medical officer a very unreasonable amount of work for a very disproportionate payment. It shows, moreover, that the unfortunate medical man is expected to do horses' work. Dr. Keily says in one letter that he had sometimes to pay twenty visits a day to infectious cases. With so many cases, such long distances, and a day of only twenty-four hours, a cab was indispensable; but this was begrudged, save for one hour a day; and he was asked, in addition to his abundant work, to supply the committee with a few interesting statistics—such as a list of home patients, the time given to each, how long the hansom was at the door, and the cost of each prescription. Fancy a medical man, with a district nearly twenty miles in circumference, with twenty infectious cases a day to visit, temperatures to take, and all his other patients to see, being thought of as having infinite leisure, with time to construct statistics like the above. Dr. Keily properly declined to give such statistics unless he was supplied with a secretary and when asked what he would take as a substitute for cab

Digitized by Google

fare said £100 a year. Moreover, he wisely threw upon the committee the whole responsibility of refusing proper allowances for cabs, and ceased to see a number of the permanent or distant cases. It is significant to see such men renounce these appointments, and expose the shabbiness and unreasonableness of the societies that expect so much from and give such pittances to their medical officers. After Dr. Maunsell's experience at Bath and Dr. Keily's at Plymouth, gentlemen taking these appointments will deserve no sympathy from the profession. The new rules are more ungenerous than the old ones; they involve, too, the undertaking on the part of a medical officer not to go to law, and to submit every grievance to the Committee of Management, and as a last appeal to the General Committee.

UNUNITED FRACTURE OF CLAVICLE.

THE case that formed the subject of a communication to the last meeting of the Clinical Society by Mr. A. E. Barker possessed considerable interest from many points of view. As Mr. R. J. Godlee and the author pointed out, the presence of an ununited fracture early in life generally carried with it the impression that there existed some vice of the constitution rendering normal processes of osteal repair impossible of occurrence. Mr. Barker is therefore to be congratulated on the successful issue of his operative procedures. The case in question was, however, not solely interesting from the surgical point of view, but practically successful in the mending of the clavicle as well as in the relief of certain nervous and muscular symptoms, which constituted a source of annoyance and disability to the remarkably intelligent boy. Dr. Poore supplied the detail of the medical facts: tenderness of the trunks of the brachial plexus; diminished faradaic irritability of that important muscle of manual prehension and precision, the right first dorsal interosseous; want of development of the pectoralis major on the affected side; slight mottling of the skin and grooving of the thumb-nail, with diminished rate of growth of the finger-nails. From personal examination Dr. Poore was able to testify to the disappearance of all these morbid phenomena. A conspicuous symptom, however, that probably determined the application for relief, was the inability on the part of the boy to continue writing for more than a few minutes. At the end of ten minutes the manuscript was altogether illegible, and the difficulty with which any strokes of the pen were made was great and painful. The symptoms, so far as the writing was concerned, had a kind of resemblance to those of "writer's cramp," though the difference between the genuine disease and this imitation was sufficiently obvious, justly calling forth the remarks of Dr. Poore and Dr. Hughes Bennett. The last point that remains to be related is the absolute recovery of the power of writing—a desired result that ensued so distinctly on the operation that surgery may justly claim another success in diseases of the nerves.

TOXIC ACTION PROPORTIONAL TO ATOMIC WEIGHT.

THE salts of the rare metal rubidium act as heart poisons like those of potassium and lithium; and Richet, who has examined the action of these substances on both warm- and cold-blooded animals, finds that these metals are poisonous in almost exactly the inverse ratio of their atomic weights (lithium 7, potassium 39, rubidium 85), so that the minimum lethal dose of rubidium is about a twelfth of that of lithium, that of potassium being intermediate between these. It appears, therefore, that the toxic action is really a chemical one, the chlorides of the metals acting by displacing molecule for molecule, the chloride of sodium in the tissues.

THE LAW RELATING TO VACCINATION.

AN important question under the Vaccination Acts has been raised in a case in which counsel on behalf of Lord Clifton moved for a *certiorari* to remove into the Court of Queen's Bench an order made by magistrates in the Isle of Thanet in respect of Richard Fox, Lord Clifton's valet, that his child should be vaccinated. The Court having granted a rule *nisi*, the case will doubtless come on for discussion. It appears that the valet had an unvaccinated child, and that he objected to its being vaccinated with humanised lymph; and the child remaining unvaccinated, the man was summoned, and Lord Clifton arranged either to appear himself on behalf of the valet, or to engage the services of a solicitor. But being absent in connexion with electioneering duties, he asked the magistrates to adjourn the case; the request was, however, not complied with, and an order was made directing the child to be vaccinated. The clause under which the order was made is Section 31 of the Vaccination Act, 1867, which enables a magistrate to order the appearance of the defaulting parent or person with the child before him, and "upon the appearance" he may, if he deem fit, make an order as to the vaccination of the child. In this case the parent failed to appear either with or without the child, either in person or by any legal representative, and it is contended that the order was, in consequence, invalid. It has already been decided in the case of Dutton *v.* Atkins, 6 Law Reports, Q.B., 377, that the appearance of the child is not an absolute necessity, provided the magistrates are able to judge that it remains unvaccinated; but the question as to whether the order can be issued in the absence of the parent has, as yet, never been decided. The parent may appear by any member of his family, or any other person authorised by him in this behalf, but apparently his non-appearance can only be dealt with under Jervis's Act, 11 and 12 Vict., cap. 42, sec. 2.

INJECTIONS INTO THE LUNGS.

A DISCUSSION has recently taken place in the Medical Society of the Paris Hospitals, chiefly between M. Gougenheim and M. Dieulafoy, on the advantage of practising antiseptic injections into the tissues of the lungs in cases of phthisis. M. Gougenheim had injected bichloride of mercury in thirty-three cases of advanced phthisis with considerable amelioration, the loss of flesh being retarded and the râles as also the expectoration diminished. M. Dieulafoy, on the other hand, had in 1881 practised injections of glycerine of carbolic acid, colouring this with cochineal, by which means he was able to assure himself by inspection of the sputa that the antiseptic had entered a cavity. He found, however, that the patients suffered great pain from the injections, and that no beneficial effects followed, so that he soon abandoned this treatment.

THE DRAINAGE OF DWELLING-HOUSES.

THE Plumbers' Company are taking a step in the right direction. For some reason or other, justly or unjustly, the plumber has for years been the pet aversion of the householder and the favourite butt for the wit of those who delight in holding up "the British working man" to ridicule. On the 24th inst. a special court of the Company was held to confer with a meeting of the plumbing trade of London, with respect to certain resolutions which had been passed to give practical effect to the decisions of a conference of metropolitan and provincial plumbers and to secure the greater efficiency of plumbing and draining work in connexion with dwelling-houses. These resolutions provide for a system of registration, the register to be open to the admission of those who give evidence of their present status and experience in the trade—to those who pass a qualifying

Digitized by Google

examination, or to those who produce certificates of competency. A plumber who is doing dishonest or unskilful work is doing an evil to the public, and a thorough system of registration will go a long way towards the removal from the trade of those who now disgrace it. At present there is in this country no requirement of evidence of qualification—a state of things which we believe is not tolerated in any other trade or profession which involves the security of the health and life of the public. A council composed of distinguished sanitarians, members of Parliament, medical officers of health, and members of some of the chief municipal bodies, has been formed to carry out the object which the promoters of the scheme have in view, and it is to be hoped that their efforts towards the attainment of a result so pregnant with good may be attended with success.

INTRA-UTERINE BRAIN DISEASE.

CASES of micro-cephalus are of frequent occurrence, and this clinical sign, together with want of intellectual development, are together or alone the chief features of most congenital diseases of the brain. The size of the head appears to be a more or less accidental circumstance, and certainly gives but little clue to the anatomical condition of the concealed brain. From the material that has already been collected, it would appear that the morbid anatomy of congenital brain disease is far more varied than the clinical pictures of such cases. It is true that motor symptoms are frequent accompaniments of mental defect in such cases, but the number of symptoms is small, from the circumstance that there has been an actual want of development of normal functions. In congenital brain disease the chief feature is sometimes atrophy, more especially of the motor convolutions; this forms one variety of porencephaly. At other times we have to do chiefly with sclerotic conditions. Tumours and cysts have also constituted the anatomy of some cases. As a contribution to the pathology of sclerotic conditions of the brain, the cases narrated by Dr. Ashby and Dr. T. Barlow at the last meeting of the Pathological Society are of much interest and importance. Congenital syphilis is probably responsible, for many cases of intra-uterine cerebral sclerosis and syphilis may act in the ordinary way by producing patches of fibroid induration, or by causing characteristic changes in the vessels, with consequent atrophy and sclerosis. Dr. Barlow also considered that meningitis, however produced, may lead to sclerosis of the cerebral tissues. The subject is one which urgently requires more extensive post-mortem experience, and it is a field in which there is much room for original investigation.

THE "JAW-JERK."

UNDER this name, compounded of familiar terms, Dr. de Watteville describes in the current number of *Brain* a phenomenon analogous to the "knee-jerk" or patellar tendon reflex. As the extensor muscle of the leg when suddenly stretched contracts by a sharp tap on the tendon, so the masseter and other muscles of mastication contract when similarly excited by an extensile impulse. The latter is best imparted by applying a flat object, such as the handle of an ivory paper-knife, on the teeth on either side of the jaw, and using an ordinary percussion hammer to strike the required blow. The jaw should not be fixed by any voluntary muscular contraction, and the blow should be struck as near the teeth as possible. The short period of latency of the jaw-jerk, ·02 of a second, is held to be another argument against the reflex nature of the tendon reaction. The jaw-jerk is exaggerated in many cases of disease, and may even pass into a regular clonus. The latter phenomenon was observed five years ago by Dr. Beevor in a case of amyotrophic lateral sclerosis, published in the current number of *Brain*. Dr. de Watteville mentions a case of hysterical spasms in which the jaw-clonus was present. Further experience alone can show what variations in the jaw-jerk are compatible with health, and determine what diagnostic value its exaggeration and abolition may possess.

A TERRIBLE OPERATION.

IN a recent number of one of the leading medical serials of continental Europe, several pages are devoted to the description of a truly terrible operation. The patient, a middle-aged woman, of strong constitution, had suffered from mammary cancer for upwards of fifteen years. The disease, slow at first, had lately made rapid progress to induration and ulceration. The axillary cavity was obliterated, and the largely swollen arm could not be abducted. The patient being thoroughly anæsthetised, and all antiseptic precautions taken, the operator divided the clavicle at the junction of its inner and middle third. Raising the acromial end, and dividing the subjacent structures, hard sclerotic tissue was found surrounding the subclavian vessels. The artery and vein were tied separately near the scaleni, after separating with much difficulty the lymphatic glands infiltrated with carcinomatous tissue which was continuous with the hardened ulceration in the chest and strongly adherent to the rib. This procedure occupied an hour, and it was followed by amputation of the arm and excision of the scapula and of considerable portions of the second, third, and fourth ribs. The patient was still alive, but pale and with a thready pulse; yet, wonderful to relate, death did not occur until four hours later. We are assured that the procedure was sanctioned by a formal consultation of surgeons, and the operator closes his description with the hope that his example may be followed under more favourable circumstances. But on what grounds, anatomical or clinical, is there reason for believing that such a terrible mutilation can have any other result than the patient's speedy death? Our motives in suppressing names and place will doubtless be correctly interpreted by our readers, who must accept our abstract as an authentic record of proceedings in the chief hospital of one of the principal European cities in 1885!

INFLUENCE OF HOT DRINKS ON DIGESTION.

VARIOUS opinions are held by the public, and we believe by medical men also, on the effect of hot drinks on the digestion of food. This matter has lately been investigated by Dr. V. E. Nyeshel of St. Petersburg. The plan he adopted was to make use of twenty patients in the surgical wards of the Obukhoff Hospital suffering from fracture of the fibula, contusion of the foot, and such-like affections, and dividing them into two sets of ten each, to find out first by a three days' experiment the length of time an ordinary meal of soup, meat, potatoes, and black bread required for digestion. For this purpose the stomach-tube was employed at periods varying from five to seven hours and a half after the meal, and the condition of the contents of the stomach examined. In all the cases complete breaking down appeared to have taken place in about six hours and a half. The exact time required by each individual for the digestion of the specified meal being noted, further observations were made on a subsequent day, the patients in the first group being given after the meal hot tea at a temperature of from 40° to 75° C., the quantity taken varying from two to eight tumblerfuls. The contents of the stomach were drawn off at the time when, as former experiments had shown, digestion would under ordinary conditions have been complete. The result was that, when not more than three tumblerfuls of hot tea had been swallowed, it was found that digestion had pro-

Digitized by Google

greased just as well as without it, but a larger quantity of hot tea appeared distinctly to retard the digestive process. The second group of patients were given a meal similar to what they had had before, but hot. On examining the contents of their stomachs no difference could be detected between the rate of digestion of hot and cold food. The author found that by painting the pharynx with a 5 per cent. solution of hydrochlorate of cocaine the tube passed easily and quickly.

DISEASE OF THE MEDULLA OBLONGATA AND HEMIANÆSTHESIA.

M. VULPIAN made an important communication to the Académie des Sciences on the 11th inst. on the subject of hemianæsthesia. Following up a former note on the subject in which he had pointed out the connexion between this affection and bulbar lesions, he detailed a case where the right side of the bulb had been diseased and in which there had been cross-anæsthesia—the right side of the face and the left limbs. Experiment had given results of a similar character. He had performed unilateral section of the bulb in animals, and thus produced experimentally a hemianæsthetic condition exactly corresponding with that existing in the case above mentioned. The explanation is to be found in the anatomical disposition of the nervous fibres of the medulla, where the sensitive root of the trigeminus of the same side is in juxtaposition with the encephalic fibres which cross at the same level.

"A MEDICAL MAN"—QUERY.

SOME of our contemporaries, who would not willingly tarnish the fair name of the medical profession, occasionally do so inadvertently in their police reports. Cases not infrequently are reported in the daily papers in which a person charged is described as "a medical man," "physician," &c. In these cases a reference to the Medical Register generally fails to corroborate the inference that they are legally qualified members of our profession. We do not hesitate to admit that now and again, even within the bounds of the Register, a "black sheep" does appear. But that is no reason why anybody who pleases should call himself "a medical man," and have his claim allowed. We would point out that copies of the Medical Register are annually distributed to the Law Courts, in order that, amongst other things, such mistakes may not be made.

TRAMWAY AND 'BUS MEN.

It seems strange, in this age of "short hours" and "early closing" movements, that a resolution should need to be moved to the effect "That the directors (of a tramway company) be requested to reduce the hours of work for drivers and conductors from sixteen hours to fourteen, giving every other Sunday off duty." Except railway, tramway, and 'bus servants, probably no members of the so-called labouring classes in the country work more than twelve hours out of the twenty-four. The most urgent reasons for a change in this particular are set forth clearly enough in "The Story of Our Tram-car Men"—a pamphlet which we commend to the attention of all who are interested.

RHODOMYCES.

Rhodomycosis, according to Dr. Wettstein, is a fungus closely allied to oïdium albicans, but differs in the appearance of the conidiophores, the modes of formation of the conidia, especially in its unseptated hyphal branches. The fungus was found in the fluids ejected by patients suffering from pneumonia. It presents itself as a dense, delicate, pink growth, containing enormous numbers of conidia.

MANGANESE IN PLANTS.

"DETERMINE the place and mode of action of manganese in the vital processes of protoplasm." When may such an imperative proposition be asked the student with any probability of obtaining an answer? An interesting paper by Professor Flückiger in the *Pharmaceutical Journal* (p. 621) opens by asserting the wide extension, though limited amount, of manganese in the vegetable world. Certain plants are said to have the power of absorbing the metal, others are unable to assimilate it. Much more striking facts of a similar order may be noticed with regard to iodine. Flückiger showed in 1872 that the plants of the natural order Zingiberaceæ are remarkable for the manganese that every part of most of the plants contains. Trapa natans, especially its fruit, is rich in manganese, although it grows in swamps that contain only an extremely small amount of that metal. There are two species of Trapa in the East, playing a most important part in the food of the Indian and Chinese population. Herr Lofander succeeded at Flückiger's laboratory in demonstrating the presence of manganese in the ash of the fruits of Trapa bicornis. According to some authorities, Trapa natans appears to be dying out, but this would appear on Tägçi's belief to be a correlative of the disappearance of swamps, which is the natural habitat of the "water-nut." Trapa bispinosa, indigenous in Bengal and the Peninsula, in the Punjaub as well as in Cashmere, yields enormous quantities of a most valuable contribution to the provisions of the people of India, where as Drury says in his "Useful Plants of India," the plant is largely cultivated.

SUPRAPUBIC LITHOTOMY.

M. POLAILLON recently showed at the Société de Chirurgie the urinary organs of a calculous patient upon whom he had unsuccessfully attempted suprapubic lithotomy. The bladder was distended by an injection of 150 grammes of fluid, and the rectum was distended in the usual manner; but in spite of these steps M. Polaillon found, when he made his incision through the linea alba, that the peritoneum extended over the bladder quite down to the pubes. He verified this by making an incision into the serous sac, through which he introduced his finger and exactly traced the reflection of the peritoneum. He therefore sewed up the wound and abandoned the operation. The wound healed, and several months later the patient died of pyelonephritis. At the necropsy the bladder was found to be hypertrophied and contracted, fitting closely around a stone measuring in circumference four centimetres by two. The peritoneum passed quite down to the pubes. The ureters were much dilated even to their orifice into the bladder, and M. Polaillon suggests that the fluid thrown into the bladder passed into the ureters and distended them instead of the bladder, that the rectal dilator passed in above the bladder, and that thus both these means failed to raise the bladder. However, without an actual demonstration of the truth of these views—and this was not made a the post-mortem—we are not forced to accept them as the explanation of the failure of the operation.

DISCHARGE OF AN OVARIAN CYST PER RECTUM.

SOME months ago the *New York Medical Record* contained an account of a case in the practice of Dr. H. W. Carpenter of Oneida, N.Y., in which a patient had been tapped of thirty-five quarts of fluid, albuminous to the extent of 75 per cent., in an ovarian cyst. She was then in extreme distress from distension and peritonitis, and hopeless of life. "She rallied well from the operation," says Dr Carpenter, "and in about six weeks there was per-

Digitized by Google

foration of the colon, as near as could be ascertained, at the sigmoid flexure, and the fluid which had slowly accumulated in the sac was discharged *per rectum*, and on May 15th *the entire sac passed off*." The patient soon began to improve in strength and flesh, and was able to ride five or six miles without fatigue, and, with the exception of slight pain in the right iliac region, she felt quite well. This is a remarkable case. It would be interesting to have two or three questions answered: Did the sac come away per anum? was its pedicle or attachment divided? was it a single sac or cyst? and what were its size and weight?

EBERTH'S BACILLUS IN EMPYEMA.

AN observation which may be mentioned, as it concerns an interesting subject, has been placed on record by M. de Gennes in *La France Médicale*. The glass slips smeared with pus from a case of purulent pleurisy resulting from typhoid fever were stained in methyl blue and methyl violet. Microscopical examination revealed the presence of numerous micrococci, diplococci and bacilli. The last mentioned were elongated ellipsoidal rods, having a clear centre, but deeply stained at each extremity, in every way corresponding to the bacillus described by Eberth and Artaud as characteristic of enteric fever. M. de Gennes opines that the micrococci were the cause of the purulent pleurisy, but the bacilli he regards as the irrefutable witnesses of the enteric origin of the broncho-pneumonia that accompanied the pleurisy.

FROM the report of the examination made by Colonel Sir Francis Bolton of the water supplied by the several metropolitan water companies during the month of December, 1885, it appears that the Thames water distributed by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies again contained, in consequence of the flooded state of the river, a much larger proportion of organic matter than, until November, had been present in it for many months past. The water drawn from the Lea showed little change from that distributed from the same source in the previous month. All the samples were clear and bright on delivery. The number of micro-organisms found by the gelatine method in one cubic centimetre of the various waters were as follows:—Chelsea, 9; West Middlesex, 15; New River, 18; Southwark, 73; Lambeth, 124; Grand Junction, 134; East London, 317; River Lea (unfiltered), 2831; River Thames (unfiltered), 4650.

ON the 26th inst. the costly and nearly new office furniture and effects of the Lower Thames Valley Main Sewerage Board were sold by auction at Kingston-on-Thames, consequent on the dissolution of that ill-fated authority. The joint board being practially now at an end, several of the late constituent authorities, including the Richmond Select Vestry, the Heston and Isleworth Local Board, and the Kingston Corporation, have now taken independent action with regard to the drainage of their several districts, and have already adopted schemes which it is hoped will be accepted by the Local Government Board.

THE death has been announced of Deputy Surgeon-General M'Nab, M.D. Glas., who retired from the army in October, 1875, after a service of twenty-five years. He assisted in the suppression of the Indian Mutiny, and was present with the 64th Regiment in the operations at Cawnpore under General Windham, in the defeat of the Gwalior mutineers on the 6th of December, 1857, the action at Khalee Nuddee, and the occupation of Futteghur, receiving the Mutiny Medal for his services.

A CATALOGUE of the Library of the Faculty of Physicians and Surgeons of Glasgow has recently been issued. It is in the form of an alphabetical list of authors, accompanied by an index of subjects in alphabetical order, the authors under each subject being arranged chronologically. This is the plan on which the catalogue of the library of the Royal Medical and Chirurgical Society of London has been compiled, and it possesses many advantages. Mr. Duncan, the librarian of the Faculty, to whom credit for the work is due, is to be congratulated on the successful and satisfactory result which has crowned his labours.

AT a meeting of the City Commission of Sewers on the 26th inst., Dr. Saunders, the medical officer of health, reported that the death-rate during the past five weeks was at the rate of 5·05 per 1000 per annum, the lowest ever recorded in the City, and marvellously small considering the resident population and the fact that over three-quarters of a million of people frequent it daily. As showing the extreme fickleness, however, of the rate in the city, it may be mentioned that at the corresponding week last year it was 27·29 per 1000.

ON the arrival of the troopship *Serapis* at Portsmouth on the 22nd inst. from Bombay, it was announced that five days after leaving India, Staff-Surgeon M'Carthy died suddenly from fatty degeneration of the heart, and was buried at sea with military honours. The deceased had served in the ship for three years, and was forty-eight years of age.

AT the monthly meeting on the 25th inst. of the Board of Management of the Manchester Royal Infirmary, Dispensary, and Lunatic Asylum, a resolution congratulating Sir Wm. Roberts on the honour which has recently been conferred upon him was carried unanimously.

OWING to the recent introduction of small-pox into Cardiff by two seamen from a vessel arriving from Antwerp, it has been decided by the local authorities to apply for an inspector from the Local Government Board to visit the town.

THE strain of attention involved in the struggle between Zukertort and Steinitz, at the chess tournament in New York, is stated to be evidenced by the existence of insomnia in both combatants.

SIR HENRY ACLAND is, we learn, about to proceed to the Mediterranean, to seek, in two months' rest and change, the means of recruiting his somewhat enfeebled health.

MR. TEALE, of Leeds, will deliver a discourse at the Royal Institution on Friday, February 5th, at 9 o'clock, on the Principles of Domestic Fire-place Construction.

MR. J. BLAND SUTTON, Sir Erasmus Wilson Lecturer for the current year, has been appointed Assistant-Surgeon to Middlesex Hospital.

ANTHROPOLOGICAL MUSEUM.—A project has been started in Berlin to establish there an anthropological museum, which will do with regard to the races of men what zoological gardens do with regard to animals. In the exhibition, or garden, it is intended that representatives of various races shall permanently reside; while of such races as cannot stand the cold of the climate, representatives will be brought to Germany to reside there during the summer. An ethnological museum is to be established in connexion with the exhibition, which is said to have the support of several capitalists.

Pharmacology and Therapeutics.

AGARICIN IN THE NIGHT SWEATS OF PHTHISIS.

THE action of agaricin in arresting or modifying the sweats of phthisis was known to De Haen as early as 1767. It has since been employed by various observers for this purpose—Barbut, Andral, Trousseau, and Peter in France; Seifert, Proebsting, Pribram, Piering, and Senator in Germany; and Wolfenden, Murrell, and Young in Great Britain,—with more or less success. A series of observations has recently been published by Dr. Vitali Miller, of St. Petersburg, on seventeen cases of phthisis in which night-sweats were a prominent feature. In the majority of cases doses of from one-twelfth to one grain (a Russian grain is equal to ·996 of an English grain) produced a decided diminution in the sweats, in some cases arresting them entirely. Generally there were no concomitant unpleasant symptoms; but in a few instances some disturbance of the primæ viæ was set up, tending to justify the dictum of the old physicians, "Cutis laxa, alvus sicca; cutis sicca, alvus laxa." There were, however, cases in which even two-grain doses failed to produce any impression on the perspiration. Of the seventeen cases observed, a more or less decided diminution of the sweats was produced in twelve, while in the remaining five little or no effect could be detected. In one of these five, two-grain doses produced absolutely no effect. In another, although the first two doses produced arrest of the sweating, the succeeding five doses, which were larger, were followed by no diminution. In another case, in which agaricin was given for ten nights, complete arrest occurred twice and diminution three times, but on the remaining five nights no effect at all was observed. In another case, where the drug was given for four nights, there was arrest one night, an increase the next night, and very profuse sweats on the subsequent two nights. In another case there was only a very slight diminution produced. With regard to the twelve cases in which more satisfactory results were obtained, the following figures give the number of nights in which sweating, in each case in regular order, was diminished—6, 2, 0, 4, 5, 4, 6, 3, 1, 1, 3, 3. The nights in which the sweats were arrested were—0, 2, 4, 3, 5, 2, 4, 7, 3, 4, 3, 5; and those in which there was no diminution—4, 0, 3, 2, 3, 0, 1, 2, 3, 2, 1, 0.

TOBACCO.

The trustees of the Fiske Fund at their last annual meeting announced that they had awarded the prize to an essay on the "Physiological and Pathological Effects of the Use of Tobacco" bearing the motto "Quid nimium probat, nihil probat." The author was found to be Dr. H. A. Hare, of Philadelphia. The conclusions at which the author has arrived are thus summed up:—Tobacco-smoking does not decrease the urine eliminated, but rather increases it; tobacco does retard tissue waste; tobacco and its alkaloid cause convulsions in the primary stage of the poisoning by depressing the reflex inhibitory centres in the cord; it causes the palsy of the second stage by paralysing first the motor nerve trunks and then the motor tract of the spinal cord; the sensory nerves are not affected by the drug; nicotine contracts the pupil by stimulating the oculo-motor and paralysing the sympathetic, this action being peripheral; nicotine first lowers the blood-pressure and pulse rate, secondly increases pressure and rate, and finally decreases pressure. The primary lowering of pressure and rate is due to pneumogastric stimulation, associated with vaso-motor dilatation; the second stage is the result of vaso-motor constriction and pneumogastric paralysis; the third is due to vaso-motor dilatation returning. Death by poisoning from this drug results from failure of respiration, the action being on the central nervous system. The blood-corpuscles are broken up and crenated by the action of the poison. In death from nicotine-poisoning the blood shows changes in the spectra. Death can be brought about by cutaneous absorption of nicotine. Tobacco increases intestinal peristalsis in moderate doses, and produces tetanoid intestinal spasm in poisonous ones. The liver appears to destroy the poison, although this destruction is participated in by every [illegible] in other parts of the body. Tobacco-smoking increases pulse rate and decreases arterial pressure.

ANTIPYRIN IN RHEUMATISM AND MIGRAINE.

Professor M. A. Khomyakoff and Dr. L'voff, writing in the last number of the *Vrach*, highly praise antipyrin both in acute and chronic rheumatism. They prescribe it in from fifteen- to twenty-grain doses four times a day, and find that in acute rheumatism it very quickly relieves the pain and reduces the swelling without producing any unpleasant effects. It was successful, too, in two cases in which salicylate of soda in large doses had entirely failed to afford relief. Antipyrin proved equally valuable in muscular rheumatism, rheumatic pains in the head and limbs, and in neuralgia of rheumatic origin. It was also employed in twenty-five cases of migraine and pains in the head arising from various causes. In most of these cases the first dose of from fifteen to twenty grains of antipyrin produced a marked alleviation of the pain within twenty minutes. If no effect were produced, a second dose was administered half an hour after the first, and even in the severest cases this did not fail to relieve. Unfavourable symptoms did not present themselves at all throughout the investigation.

ADONIS VERNALIS AND ADONIDINE.

M. Henri Huchard has reinvestigated the action of adonidine on the heart and vessels. Durand has related a case in which he had been able to give sixteen centigrammes a day with impunity. But Huchard avers that he would never dare to go beyond two or three centigrammes of the glucoside, and even then nausea, vomiting, and epigastric pains may be caused. The action of the medicine is rapid, and even on the first day the effects on the urine and on arterial tension may be observed, as well as on the heart. Its elimination probably takes place rapidly, since all its results disappear a few days after the suspension of the drug. Notwithstanding the value of adonidine, Huchard thinks it cannot be regarded as the successful rival of digitalis.

A SOPORIFIC IN DYSPNŒA.

Withania somnifera, which was known to the ancients as a sleep-inducing drug, has recently been employed by Dr. Trabut of Algeria in cases of alcoholism, emphysematous dyspnœa, and phthisis, for the purpose of inducing sleep, with a considerable amount of success, greatest apparently in the former two classes of cases. In some respects it appears to Dr. Trabut to be a more trustworthy hypnotic than opium. A tincture, which is very bitter, a crystalline sulphate, and an extract have been prepared by M. Duval, professor of chemistry, who recommends the extract in pills. It is stated not to have a mydriatic effect.

THE INTERNATIONAL CONGRESS OF HYGIENE.

To all who have realised that a high degree of perfection in sanitary matters will not be easily attained unless sanitary reforms assume an international character, the announcement that the sixth Congress, which was to have been held at Vienna this year, has been postponed will be received with regret and surprise. The International Congresses of Hygiene have met regularly every other year for the last ten years. The towns of Brussels, Paris, Turin, Geneva, and the Hague all faithfully fulfilled their promises, received and gathered their guests from all parts of the world, carrying out the programme established by common consent with much skill and hospitality. For some reason, as yet unexplained, Vienna has thought fit to break through the traditions and postponed for a twelvemonth its invitation to the Congress. Three years must therefore elapse before this, the most catholic of all gatherings on the subject of hygiene, can take place—a fact which, in the face of the cholera epidemic that still menaces Europe, is more especially unfortunate. One advantage, however, will accrue: the delay will give English sanitary reformers more time to prepare themselves. At these Congresses, to which some twenty to thirty nationalities send delegates, England is usually but inadequately represented. As the Congress is not confined to the medical profession, English doctors apparently take but little interest in the proceedings, and the fact that the majority of the members are medical men seems to keep engineers and architects away. On the Continent, however, though sanitation is not so fully developed as

Digitized by Google

in England, it is well understood that medical men are not alone responsible for the preservation of public health. The services of the chemist, the architect, the engineer, and the public administrator are also indispensable; and it is the special merit of these international Congresses of Hygiene that they have brought together eminent men belonging to all these professions, and representing all the important and many of the less powerful nations of both hemispheres. There is now, in consequence of the postponement, eighteen months to prepare for the next Congress; and we trust that by that time not only will England be powerfully represented, but the English delegates will be able to propose that the Congress hold its seventh meeting in London. No nation has taken a more active part in the development of hygiene, and Englishmen should not be slow to impart their knowledge and practical experience to the representatives of foreign countries. It seems strange that we should remain comparatively inactive in such a cause when small continental towns like the Hague and Geneva have given proof of boundless hospitality and great public spirit.

The report of the work of the sections at the fifth Congress has recently been published. It is issued for the Congress by the Imprimerie sud Hollandaise at the Hague, and was compiled by the secretary-general, Dr. Van Overbeek Meijer. Each speaker was requested to write a summary of his own speech either in French or German. These, when printed, were sent to the author for correction, and then gathered together in the present volume. We thus have before us in compact form the opinions of eminent hygienists belonging to various nations. The accompanying graphic maps and charts serve to illustrate the theories propounded. These embrace, among other subjects, the rival systems of drainage, the English water-carriage, the Dutch Leirnur, and the French Berlier pneumatic drainage; the influence of wood plantations on climate, with the views of the representative of the Russian Government on this question; conclusive evidence from the Dutch delegates concerning the spread of epidemics by the importation of rags; Dr. Brouardel's proposals and arguments in favour of international laws to prevent the adulteration of food; a learned theory by Dr. Thirzinga on over-pressure at school; Dr. Vallin's experiments in conveying tuberculosis to animals by milk from diseased cows; Dr. Roth and Van Dooremaul on the prevention of blindness; speeches, charts, and statistics on the effects of alcoholism in Switzerland and Holland; Dr. Napias, on the factory legislation of all nations; Dr. Layet, of Bordeaux, on voluntary restriction of procreation; Dr. J. Bertillon, speeches and maps showing the districts of Paris most affected by the leading zymotic diseases, and some very interesting statistics and charts on the comparative mortality in the various professions and trades of Switzerland. Thus it will be seen that the problems studied were of considerable practical interest, and we have mentioned but a few out of the number.

REPORT ON THE SANITARY MEASURES IN INDIA IN 1883-84;

TOGETHER WITH MISCELLANEOUS INFORMATION UP TO JUNE, 1885. VOL. XVII.

THE information contained in this volume, so far as regards the health of the European and native armies, the prisoners in the gaols, and the civil population of India, has already appeared in the report of the Sanitary Commissioner with the Government of India. As we noticed the more important facts in our review of that volume, it seems unnecessary to go over the ground again. (See THE LANCET, April 11th, 1885.) There are, however, some points to which we may call attention.

There seems to be a fair progress in vaccination, though it is still very far from being general. During the year under review there was an extension of the Compulsory Vaccination Act in Bengal to fifty-six towns and four thannahs. The value of vaccination is shown by the fact that, while the mortality from small-pox was ·25 per 1000 in unprotected areas, it was only ·07 per 1000 in those that were thoroughly protected. The use of bovine lymph was extending, and the demands for it increasing so much that the establishment was scarcely able to meet them. It is stated that in Madras inoculation is very much practised by the people, and "as it interferes greatly with the progress of vaccination, the Inspector of Vaccination has suggested that an Act should be passed prohibiting inoculation in those districts where vaccination can be had."

In Calcutta the operation of the Contagious Diseases Act was suspended from March 15th, 1883, and apparently with the same result as at home, an increase of venereal disease. Surgeon-General Payne, reporting on the effect of this during the remainder of the year, stated "that the measure had in the course of nine months undone all the good that had been accomplished. The statistics furnished by Dr. Payne apparently show that the withdrawal of the Act had resulted in injury to the health of certain classes of the population."

The report of the medical schools appears to be satisfactory. At the Calcutta Medical College, and the Grant Medical College, Bombay, female students were for the first time admitted, and it is stated that some very promising candidates have presented themselves.

Throughout India the questions of the water-supply and drainage of the towns appear to be receiving increased attention, and the works for these purposes to be making steady, though we fear slow, progress. In Madras the extension of the water-supply throughout the town was completed, and in Bombay considerable progress was made in the works for its improvement. Among the military works in Bengal may be specially noted "the completion of the Peshawur water-supply scheme, the extension of the Umballa water-supply, the provision of water to Pishin, and the commencement of the supply of water to Chakrata." In Madras the water-supply of Bangalore was receiving attention, and steps were being taken to "put a stop to the long-standing nuisance in Fort St. George, caused by the discharge of fetid sewage from the main drain into the sea, just outside the fortification." At Secunderabad, also, a scheme for the much-needed improvement of the drainage of the town was under the consideration of the Resident.

At a time when so much attention is being directed to the most advisable measures for the prevention of the spread of cholera, the following remarks by the Army Sanitary Commission are of special interest: "Were it not that we have other experience in India than that furnished by the civil population, our hope of reducing cholera mortality, by the removal of its local causes, would be very small. But such experience as we have throws a totally different light on the figures of the preceding table [of the registered cholera deaths], and converts them into indices of great local sanitary negligence. For example, local fairs and pilgrimages, which used formerly to be the real foci of local epidemics, have ceased to be so wherever cleanliness has been enforced, pure water provided, and overcrowding prevented. This rule holds universally—subject, however, to a very instructive exception, and this is, that the absolute immunity of the people at these fairs depends, to a certain extent, on the epidemic intensity in the district where the fair happens to be held. If the district mortality be not excessive, the fair-people will escape; but if the district mortality be high, some of the fair-people will suffer, but never to the ratio of the local population. That is on the supposition that the usual precautions are adopted." Under the head of General Remarks (p. 141) the Army Sanitary Commission has given a short but very clear and interesting account of "the attempts which have been made by the use of the microscope, and by other methods of inquiry, to obtain some knowledge of the pathology and etiology of the disease," and of the discussions which have taken place regarding it, with special reference to Professor Hallier's rice fungus theory, and the investigations by Koch, Klein, Lewis, and others into the subject of the cholera bacillus. The practical conclusion at which they have arrived is that expressed by Dr. Cuningham, "Once accept the great principle that the improvement of local conditions is the one and only principle on which the State can act with advantage in matters of public health, and the solution of the whole question will be comparatively easy. Sanitary administration will then no longer attempt to accomplish impossibilities, but will be directed to those great practical reforms which cannot fail to improve the health and thereby add to the happiness and prosperity of the people." The report contains a great mass of information respecting the distribution of disease throughout the various divisions of India, and the means which have been adopted, and those which are still in progress, to improve the sanitary conditions alike of the military and civil population.

SUCCESSFUL EXTIRPATION OF AN ENDO-CRANIAL TUMOUR.

THE latest *Bullettino* of the Royal Academy of Medicine of Rome (1885, No. 7, p. 247) reports a communication of exceptional interest by Dr. Durante. The patient, Signora C. B——, of Narni, aged thirty-five, was of sound constitution. The left eyeball projected forwards and outwards, but its movements and functions were unimpaired. The deformity had commenced about three months previously, and was preceded by the following symptoms: gradual loss of the sense of smell to complete extinction; perceptible impairment (*affievolimento sensibile*) of memory, particularly with reference to names; a feeling of uncertainty on movement, and, to use the patient's words, a sense of emptiness (*vacuità*) about the person. Motility and sensibility to heat and pain were experimentally proved to be normal. Hearing, taste, and the gastro-enteric functions were normal. The nasal cavities were explored with negative result. The lady's husband stated that her formerly gay disposition had become melancholy, although she did not seem much impressed by her ailment. The disturbance of memory, loss of sense of smell, and the subjective and objective state of the patient, convinced Dr. Durante of the existence of a tumour within the cranial cavity, which had destroyed the olfactories, compressed the anterior lobes of the brain, and penetrated into the orbital cavity through its roof. The patient, fully warned as to the importance and uncertainty of the operation, assented to it, and Dr. Durante performed it on June 1st in the presence of several colleagues. He commenced by making a curved incision from the inner angle of the left palpebral aperture to the glabella, and hence in a straight line upwards almost as far as the hair. The soft tissues having been raised from the bone, an opening was made into it layer by layer (*a strati a strati*) with a hammer and chisel. A portion of the frontal bone was removed to the extent of about two square inches (*circa cinque centimetri quadrati*). We proceed to translate the conclusion of Dr. Durante's narrative:—"I found that the frontal sinus had disappeared, the inner wall having been forcibly pushed against the outer one. On removing the inner table I found myself in the presence of the tumour, which I began to remove very carefully by means of a spoon. After having removed the greater part of it, I perceived that its only point of attachment was the dura mater covering the left lobe; hence I found it easy to enucleate it throughout its whole extent from the left anterior fossa and part of the corresponding right fossa at the base of the brain. The tumour reached as far back as the anterior clinoid tubercles of the sella turnica. Corresponding to the left cribriform plate of the ethmoid, a prolongation of the tumour descended into the ethmoid cells. Having excised the tumour from its connexion with the dura mater, I noted that it had depressed the orbital roof without penetrating it, and had reduced to the smallest limits the left anterior cerebral lobe and flattened the right one. The left lobe appeared substituted by the tumour, which in its entirety was equal in volume to an apple. Having carefully arrested the flow from the bleeding surface and introduced a drainage-tube into the cranial cavity through the left nasal fossa, I united the wound of the soft parts for healing by the first intention. The operation lasted about an hour. The loss of blood was relatively not great. The patient bore chloroform very well, and woke up slowly. Reaction was complete the third day. The wound had a perfectly aseptic course, the drainage-tube acting well in carrying off a very large quantity of serum slightly tinged with blood. The fourth day the patient was very prostrate. She was sleepy, indisposed to talk, and complained of great mental confusion. The drainage-tube had ceased to act during the night. I drew it a few lines downwards, and it began to yield a few drops of turbid serum. With a small indiarubber pump I injected the external aperture of the tube, and thus obtained about thirty grammes of liquid. The dropping was constantly re-established, and continued the whole of the following day and night. The alarming symptoms disappeared step by step the subsequent day. On the seventh day I removed the points of suture, and on the ninth the drainage-tube. In fifteen days the patient returned home perfectly well, without, however, having recovered the sense of smell or much improved in memory. In spite of general weakness, due to the operation, the patient said she no longer experienced the indefinite sense of emptiness around her. There was no appreciable sign of reproduction of the portion of bone removed; the displacement of the eyeball was in part reduced. Three months later I again saw Signora B——. She was very happy to inform me that her mental faculties and her normal state had been restored, and that gradually she had regained the sense of smell. This fact surprised me all the more that I was convinced of having destroyed the left olfactory during the operation, in removing that portion of the tumour which had penetrated the cribriform plate of the ethmoid. I therefore made some experiments, causing the patient to smells some aromatic substances with either nostril. I found that smell was normal on the right side, and entirely lost on the left. Microscopic examination of the tumour proved it to be a fusi-cellular sarcoma arising from the dura mater. Only one such operation is recorded in surgical history. That was performed by Amidon in America some months since, but the patient died of meningitis on the eleventh day."

ACTION OF SUNLIGHT ON MICRO-ORGANISMS.

AT the last meeting of the Royal Society, on Jan. 14th, a paper on the Action of Sunlight on Micro-organisms was read by Dr. DOWNES, medical officer of health for the Chelmsford combined districts. In previous papers to the Society in 1877, 1878, and 1879, the author, conjointly with Mr. T. Blunt, showed that sunlight was fatal to saprophytes by a process of hyperoxidation thereby induced. In this process the more refrangible rays were the most active. In the course of the research two other facts of importance also came out. It was found that in the presence of free oxygen the molecule of oxalic acid might be entirely resolved into water and carbonic acid by the action of light, more especially of the more refrangible rays, $C_2O_4H_2 + O = 2\,CO_2 + H_2O$. Further, it was discovered that the alterative ferment of cane sugar (a representative of the singular and important bodies, the diastases, which play so important a part in animal and vegetable economy) was oxidised by sunlight. These investigations have not as yet been repeated as a whole, but each point put forward in them has now been confirmed by independent observers.

After a reference to the results obtained by Professor Tyndall in 1881, and by others, the author summarises the recent work of Professor E. Duclaux, who finds that micrococci are apparently far more sensitive to sunlight than the spore-forming bacilli. Dr. Downes and Mr. Blunt, in their original memoirs, had noted the variation of resistance of different organisms—e.g., of the hypho- and saccharo-mycetes—as compared with the ordinary putrefactive bacteria; and the former now describes a specially resistant form of bacterium, resembling, but not identical with, the asco-bacteria of Von Teighem. Duclaux coincides with Downes and Blunt in regarding the process as an oxidation, and confirms their results as to the destruction of diastase by sunlight.

In refuting the conclusion of Dr. Jamieson, an Australian observer, that the injurious effect of sunshine on micro-organisms is simply a result of heat, Dr. Downes gives an account of recent experiments of his own, which indicate that a similar action, though of course in less degree, is exercised by diffused light. He concludes with a reference to the well-known observations of Pringsheim on the destruction of vegetable protoplasm by light, and claims them as evidence of the truth of his former generalisation that the hyperoxidation of protoplasm by light is a general law, from the action of which living organisms are shielded by a variety of protective developments of cell wall, aggregation of tissue or colouring matter, and in other ways.

AMONG the members of the recently formed Royal Commission to investigate and report upon the condition and education of the deaf and dumb are Drs. T. R. Armitage, R. M'Donnell, and W. T. Robertson.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5813 births and 3966 deaths were registered during the week ending January 23rd. The annual death-rate in these towns, which had been equal to 22·5 and 23·8 per 1000 in the preceding two weeks, declined again last week to 22·4. During the first three weeks of the current quarter the death-rate in these towns averaged 22·9 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1876-85. The lowest rates in these towns last week were 10·4 in Birkenhead, 16·1 in Leicester, 17·2 in Oldham, and 17·3 in Halifax. The rates in the other towns ranged upwards to 26·3 in Liverpool, 27·9 in Plymouth, 30·0 in Blackburn, and 30·4 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 448 and 435 in the preceding two weeks, further declined last week to 407; they included 159 from whooping-cough, 100 from measles, 38 from "fever" (principally enteric), 38 from scarlet fever, 38 from diphtheria, 31 from diarrhœa, and 3 from small-pox. No death from any of these zymotic diseases was recorded last week in Halifax, whereas they caused the highest death-rates in Blackburn, Bolton, and Nottingham. The greatest mortality from whooping-cough occurred in Newcastle-upon-Tyne and Nottingham; from measles in Oldham, Plymouth, and Nottingham; from scarlet fever in Leeds and Sunderland; and from "fever" in Portsmouth, Sunderland, and Birkenhead. The 38 deaths from diphtheria included 20 in London, 5 in Liverpool, 2 in Wolverhampton, 2 in Birmingham, 2 in Hull, and 2 in Sunderland. Small-pox caused 3 deaths among the residents of London and its outer ring, 3 in Liverpool, and not one in any of the twenty-six other provincial towns. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had declined in the preceding ten weeks from 90 to 35, had further fallen to 26 on Saturday last; only 2 patients were admitted to these hospitals last week, against 11 in the previous week. The Highgate Small-pox Hospital contained 3 patients on Saturday last, no case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 518 and 534 in the preceding two weeks, declined last week to 477, and were 63 below the corrected weekly average, a noteworthy fact if the recent cold weather be borne in mind. The causes of 95, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Leicester, Sunderland, Oldham, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Liverpool, Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·9 and 23·9 per 1000 in the preceding two weeks, was 23·1 in the week ending January 23rd, and exceeded by 0·7 the mean rate during the same week in the twenty-eight English towns. The rates in the Scotch towns last week ranged from 11·8 and 13·0 in Leith and Paisley, to 25·4 and 28·8 in Dundee and Glasgow. The 570 deaths in the eight towns showed a decline of 19 from the number in the previous week, and included 14 which were referred to diphtheria, 7 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 6 to whooping-cough, and 1 each to small-pox, measles, and scarlet fever; in all, 36 deaths resulted from these principal zymotic diseases, showing a further decline from 45 and 40 returned in the preceding two weeks. These 36 deaths were equal to an annual rate of 1·5 per 1000, which was 0·8 below the mean rate from the same diseases in the twenty-eight English towns. The deaths referred to diphtheria, which had been 2, 6, and 8 in the previous three weeks, further rose last week to 14, of which 7 occurred in Glasgow and 4 in Aberdeen. The 7 deaths attributed to diarrhœa showed a decline from recent weekly numbers, and included 4 in Dundee. The 6 deaths referred to "fever" corresponded with the number in the previous week; 4 occurred in Glasgow. Five of the 6 fatal cases of whooping-cough, showing a considerable decline from recent weekly numbers, were returned in Glasgow; and the death from small-pox occurred in the same city. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 132 and 145 in the preceding two weeks, further rose last week to 160, but were 36 below the number returned in the corresponding week of last year. The causes of 77, or nearly 14 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 28·8 and 33·3 per 1000 in the preceding two weeks, declined again to 29·6 in the week ending Jan. 23rd. During the first three weeks of the current quarter the death-rate in the city averaged 30·6 per 1000; the mean rate during the same period did not exceed 22·7 in London and 19·2 in Edinburgh. The 200 deaths in Dublin last week showed a decline of 25 from the number returned in the previous week, and included 24 which were referred to the principal zymotic diseases, against 15 and 30 in the preceding two weeks; 17 resulted from whooping-cough, 2 from "fever" (typhus, enteric, or simple), 2 from measles, 2 from scarlet fever, 1 from diarrhœa, and not one either from small-pox or diphtheria. These 24 deaths were equal to an annual rate of 3·5 per 1000, the rate from the same diseases last week being only 2·5 in London and 0·6 in Edinburgh. The fatal cases of whooping-cough, which had been 8 and 19 in the previous two weeks, declined again last week to 17. The two deaths referred to "fever" were fewer than in any recent week, as were also the fatal cases of scarlet fever. The 2 deaths from measles were the first recorded since the beginning of this year. Eight inquest cases and 4 deaths from violence were registered; and 46, or nearly a quarter, of the deaths were recorded in public institutions. The deaths of infants showed a further increase upon the numbers in the previous two weeks, while those of elderly persons had declined. The causes of 25, or nearly 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major John Joseph O'Reilly is granted retired pay, with the honorary rank of Bridgade Surgeon.

MILITIA MEDICAL STAFF.—Surgeon-Major Edward Allen Waterworth, M.D., 3rd Brigade, Southern Divison, Royal Artillery, resigns his commission.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon James Thomson has been placed on the retired list, with permission to assume the rank and title of Deputy Inspector-General of Hospitals and Fleets.

The following appointments have been made:—Staff Surgeon Richard S. P. Griffiths, to the *Serapis;* Surgeon Cyril J. Mansfield, to the *Excellent*, additional, for disposal; Surgeons Octavius S. Fisher and Herbert P. Shuttleworth, to the *Royal Adelaide*, additional, for Plymouth Hospital; Surgeon John Lonney, to the *Lion*, additional, for disposal; Surgeon George J. Trevor-Roper, to the *Indus;* Surgeon Robert Hickson, to the *Cambridge;* Surgeon John Moore, to the *Duke of Wellington;* Surgeon John S. Fogerty, to the *Asia;* and Mr. George H. Johnson, to be Surgeon and Agent at *Teignmouth*.

RIFLE VOLUNTEERS.—5th Durham: Acting Surgeon Frederick William Gibbon resigns his appointment.—1st London (the City of London Rifle Volunteer Brigade): Arthur John Hubbard, Gent., M.B., to be Acting Surgeon.—1st Volunteer Battalion, the Royal Fusiliers (City of London Regiment): Surgeon William Johnson Walsham resigns his commission.—4th Volunteer Battalion, the Norfolk Regiment: Edward Thurlow Prior, Gent., to be Acting Surgeon.

ROYAL MATERNITY CHARITY.—The 129th annual meeting of the governors of this charity was held on the 27th inst. The number of women who received medical and other help during the past year, without removal from their homes and families, was 3331, and of these only twelve died. The financial condition of the charity is most unsatisfactory, and the trustees have been compelled to sell out £1000 of the funded stock to meet the large and constantly increasing number of patients applying for its help.

"Audi alteram partem."

ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—With reference to the article in your issue of the 23rd inst. regarding the constitution of the Council of the Royal College of Surgeons, I would beg to remark that the College was founded in order to promote the art and science of surgery; this fact is reiterated in all the charters granted to the College. It was "in order more effectually to promote and encourage the study and practice of surgery" that the class of Fellows by examination was instituted. I believe that in the interests of surgery it is desirable that the College should continue to have the power to confer honours in surgery, and that the honours should carry with them any privileges which it is in the power of the College to bestow; and, consequently, that those only who gain the Fellowship should be entitled to a seat on the Council. It is open to any Member of the College to pass the examination for the Fellowship, and I should very much like to see the second examination or that in the practice of surgery alone insisted on for Members of twelve years' standing and upwards.

It is urged that one of the reasons why Members of the College should have seats in the Council is because it is desirable that the views of general practitioners should be heard at the Council. But a very large proportion of the Fellows are in general practice. If, therefore, general practitioners have interests which it is the province of the College to advance, as distinct from those of consulting surgeons, there can be no reason why their views should not be advocated at the Council by Fellows who are engaged in the work of general practice. What I mean is, that the fact of a man being a Fellow of the College in no way lessens his power to appreciate the feelings of general practitioners, especially if he is engaged in that line of the profession; the idea above referred to consequently appears to me to be groundless, so far as it applies to Members being elected to the Council.

On the other hand, by only permitting Fellows to be elected to the Council it is possible we enhance the privileges of the Fellowship, and may lead men to seek this honour, and thus forward the objects for which the College was founded. Beyond this it seems to me most objectionable to have anything like class distinctions or interests in the Council; at the same time, to my mind, there are many sound and valid reasons why Members of the College should have a voice in the election of the Council. It is feared that if all Members of ten years' standing are allowed to vote for candidates for the Council, the voice of the Fellows will be swamped; but there are means by which this difficulty may be overcome. It is, however, useless entering into details until we know what the opinion of the Fellows is upon the subject. There can be no question that the Fellows of the College are in possession of all the rights and privileges of electing members of Council; but it is impossible for anyone at present to know what their feelings, if they have any, on this matter may be. It was to ascertain this point that I brought forward my resolution at the Council of the College of Surgeons on Jan. 14th.

I am, Sir, yours truly,

Grosvenor-street, Jan. 25th, 1886. C. MACNAMARA.

"MR. HORSLEY'S CRITICISM ON PROF. SCHIFF."

To the Editor of THE LANCET.

SIR,—The necessarily incomplete nature of the abstract of my lectures that appeared in your issue of Jan. 2nd has provided Dr. Huggard with a favourable opportunity of reviving an old story. The moral which adorns his tale, however, does not apply to my experimental demonstration of the condition of the spinal cord when subjected to Professor Schiff's experiments, for I have never injured the motor tract in any of my operations. I pointed out in my lectures that the tension of wound-exudation (not suppuration of course) on the one hand, and interference with the vascular supply of the postero-lateral portion of the cord on the other, determined a *local* degeneration in the motor tract of the same side of the cord, the area of degeneration never extending more than about two millimetres on each side of the point of section. Further, I also showed that the result described by Schiff—viz., absence of movement in the fore limb of the same side as the cord lesion, when, nevertheless, the corresponding motor centre in the opposite cortex was excited—appeared in exact proportion to the degree of degeneration observable in the motor tract, and that in two cases where the degeneration was very slightly marked, Schiff's result did not appear, although the posterior column had been perfectly divided. I am about to publish in *Brain* the full details of the experiments on which my criticism of Professor Schiff's work is based, and I trust that we shall soon have the unusual opportunity of seeing Professor Schiff's methods, details of experiment, drawings of the lesions produced, and, last but not least, a full account of the state of the motor tract (opposite the seat of operation) published *in extenso* for comparison.

Dr. Huggard's praiseworthy energy in reporting Professor Schiff's experiment last summer leads me to hope that he will furnish us with the foregoing details, since until we know, for instance, that Professor Schiff has examined the motor tract as I have described, &c., it is somewhat premature to depart from the language of ordinary criticism, and to explain my opposing results as due to "lack of success."

I am, Sir, yours faithfully,

VICTOR HORSLEY.

Park-street, Grosvenor-square, W., Jan. 26th, 1886.

THE CONNEXION BETWEEN THE PAROTID GLANDS AND THE GENERATIVE ORGANS.

To the Editor of THE LANCET.

SIR,—The interesting letters in your issues of the 9th and 16th inst. from Mr. Stephen Paget and Dr. F. L. Tayler on this subject induce me to record the following cases, which will be seen to bear on the subject from both sides of the question—viz., the occurrence of parotitis from irritation of the genito-urinary system, and, conversely, the occurrence of ovaritis in connexion with parotitis.

The first case was that of an old gentleman aged eighty-five, who was much troubled with irritable bladder. I had passed a flexible catheter on several occasions without any subsequent irritation, and as there was but little enlargement of the prostate to account for his increasing trouble, I introduced a sound, easily and without much pain, to make sure that he had no calculus. This proceeding set up great irritation, and on the second day he had violent rigors, and complained of stiffness and pain about the right parotid, which became much enlarged and suppurated, and caused death from exhaustion in about a fortnight. During the whole time the catheter was required to relieve the bladder, owing to the inflamed and swollen condition of the prostate.

The next case was that alluded to by Mr. Stephen Paget, in which an acute attack of parotitis was induced by the introduction of a Hodge's pessary, although the pessary had given great relief, and caused no apparent local irritation. This patient was fifty-eight years of age, and long past the climacteric period. As she had never borne children, we may assume that the genital organs were in a very quiescent state. She has since been able to wear the pessary with great benefit. The parotid attack lasted about ten days, but began to subside on the removal of the pessary.

The other two cases were so similar to one another that one account will serve for both. They occurred in single ladies about twenty to twenty-two years of age, both in fairly good health, when they contracted mumps from infection, and for a week seemed to progress as usual. They were then attacked with rigors and pain in both ovarian regions, the pain being intensified by moving in bed. The ovaries could be felt swollen and very tender. The acute attacks subsided in about a week, but left the ovaries still tender and enlarged for some time. In both cases the general health of the patients was considerably impaired for some months.

These cases seem to expand the idea of the connexion of the parotid with the testes and ovaries into some unexplained association of the parotid on the one hand with the whole genito-urinary system on the other; the first two cases indicating sympathy between the parotid and the

Digitized by Google

prostate and vagina respectively, and the last two between the parotid and the ovaries.

In none of these cases was there any reason to believe that the peritoneum was implicated, and in the first two the affections were evidently secondary parotitis, not mumps. Nor do I think that Dr. Tayler's septic theory can be admitted except in the first case.

I cannot help thinking that ovaritis would be found more frequently associated with mumps if it were carefully inquired for, as we know young women are very apt to conceal pains occurring in those regions unless expressly questioned about them.

I am, Sir, yours truly,

Highbury-place, Jan. 1886. ARTHUR J. CRIBB, M.D. Lond.

PROSTATIC CASTS.

To the Editor of THE LANCET.

SIR,—In a paper recently read by Sir Andrew Clark, at the Clinical Society of London, on a "Case of Acute Prostatitis, with Discharge of Hyaline Cylinders resembling Renal Cylinders," and to which your annotation of Jan. 16th directs further attention, the author remarks: "These cases with prostatic casts in the urine may be only curiosities of medical experience, but since in none of the standard works on urinary affections, and in no monographs dealing with diseases of the prostate, can any reference be found to the discharge of hyaline cylinders in prostatitis, and without careful examination they might very easily be mistaken for cylinders originating in the kidney, I have thought the case was of sufficient importance to bring it before the notice of this Society."

Sir Andrew Clark is mistaken in supposing that he has made an original observation. In two papers published by me in THE LANCET (Oct. 14th and 21st, 1882) on Prostatorrhœa—a by no means infrequent disease—a case is referred to in which prostatic casts were believed to exist in the urine, and an illustration of the deposit is given, while the subject is referred to, not by any means as an original observation, but as one generally recognised. In his book on the "Male Sexual Organs," S. W. Gross, of Philadelphia, in the chapter on Prostatorrhœa, remarks: "If the patient be requested to pass the first two or three ounces of urine in a glass, that fluid will be found to contain delicate filiform shreds, which are sometimes more than half an inch in length, and which are muco-purulent casts of the follicles and ducts of the prostate. This highly characteristic sign of the affection, when considered in connexion with the local signs and the minute examination of the discharge, the composition of which has already been sufficiently considered, is quite sufficient to establish the true nature of the trouble." Delafosse (Paris, 1885) gives an illustration of these casts, and they are described by many other authors, to whom it is superfluous to refer.

I am, Sir, yours &c.,

Glasgow, Jan. 25th, 1886. D. CAMPBELL BLACK.

THE METROPOLITAN ASYLUMS BOARD.

To the Editor of THE LANCET.

SIR,—I have read with interest a leading article relative to the Metropolitan Asylums Board in your issue of the 23rd inst.

The evils and abuses likely to arise under the system of divided or multiple and co-ordinate authority hitherto exercised in the asylums and hospitals under the control of the managers appear within the last few years actually to have arisen, and some of them have been sufficiently demonstrated in the late Eastern Hospitals inquiry. The question therefore presents itself to the managers for their consideration, whether, if not already done, the time has not now arrived when free effect should be given to the order of the Local Government Board, dated Feb. 10th, 1875, by which sufficient authority is vested in the medical superintendent to enable him to control in their duties the officer's attendants and servants of each establishment, if duly supported by the managers. This step would, at all events, serve the one good purpose of enabling the managers with fairness to fix responsibility.

I am, Sir, your obedient servant,

Harley-street, W., Jan. 1886. JAMES ADAM, M.D.

MANCHESTER.

(*From our own Correspondent.*)

MEDICAL SOCIETIES.

THE annual meeting of the Medical Society evidenced a flourishing condition of its affairs, the number of members being 242, whilst the treasurer was able to show a balance on the right side of more than £100 on the year's receipts and expenditure, whilst there is invested in the name of the trustees, on behalf of the Society, £1110. Another member of the surgical staff of the infirmary, Mr. Hardie, has been elected president for the current year, this making the sixth year in succession that the presidential chair has been occupied by one of the staff of the Royal Infirmary. It would have been good policy on the part of the committee to have nominated someone outside the charmed circle, for there is a widespread feeling amongst many members of the profession that this distinction is confined rather too much to the infirmary staff. The Medico-Ethical Society has nominated Mr. Walmsley for re-election as president, thus following the precedent of the previous two years, when Dr. Lloyd Roberts held the same office.

HEALTH LECTURES.

The popular lectures given this winter on sanitary and popular medical subjects are more numerous than usual. Before Christmas, Miss Emily Hall delivered a very useful series on Personal and Domestic Hygiene. Then we have the annual course delivered under the auspices of the Sanitary Association, which has again this year arranged a series having a certain amount of connexion the one with the other; they all relate in some manner to food or drink, the different lecturers taking each a special article of diet. And, lastly, a course is being delivered at the Ancoats Hospital by the staff of that institution, much resembling the ordinary ambulance course. Mr. Bishop delivered the first on Surgical Emergencies, and Dr. Niven the second on Medical Emergencies. There will shortly be a vacancy on the staff of this institution, owing to the appointment of Dr. Niven to the post of medical officer of health to the neighbouring borough of Oldham. A very interesting paper on the sanitary work carried on by the Health Committee of the Corporation was lately read by Mr. Whiley, the superintendent of the department, before the Statistical Society. The magnitude of its operations is shown by the expenditure on this work, which amounts to no less than £86,000 per annum, and another £60,000 is about to be expended upon a sewage farm on Carrington Moss. Municipal work in Manchester is carried on in no pigmy style: the Water Committee are bringing us water from the lakes of Cumberland, at an estimated cost of something like a quarter of a million sterling, the engineering skill shown in this undertaking rivalling the work of a similar nature for the supply of water to Ancient Rome.

EDUCATIONAL MATTERS.

In all probability we are to have an important experiment tried in connexion with our Board Schools. A deputation from the Manchester and Salford Trades Council waited upon the School Board at their last meeting, pointing out the great importance of attempting to attract young people, boys and girls who have just left school, to evening classes; seeing that it was between the years of thirteen and eighteen that young people acquired those habits which more or less affected their whole after-life, they asked the Board to assist them in endeavouring to counteract the attractions and facilities which existed in all large towns for young people to form idle and vicious habits. Allusion was made to work of a similar kind being done in Nottingham, and the Board promised their careful consideration of the matter. At the last meeting of the Salford School Board there was rather a lively passage of arms between some of the members over the management of the industrial schools. If the statements made be correct—viz., that the children have to attend at 6 A.M., that little children of ten years of age have to clean the floors, and that their dinner consists of suet-pudding six days in the week and pea-soup on the sixth—they are certainly not being reared as hothouse plants.

BUTTERINE.

It cannot be said that the Adulteration of Food and Drugs Act is a dead letter here, for scarcely a week passes without

Digitized by Google

prosecutions being instituted against offenders. The latest raid has been upon the butter-dealers, a number of whom were recently convicted and fined for selling butterine in lieu of the genuine article. It is a pity that this article is not sold in an open and honest manner, as it is undoubtedly a useful and legitimate food stuff, and, as was admitted by the public analyst, very preferable to the common sort of butter which alone could be got for the same price. As one of the dealers put it, "the people know quite well what it is they buy; they like it, and come again for it."

LIVERPOOL.

(From our own Correspondent.)

THE PROVIDENT DISPENSARY SCHEME.

THE public meeting called to discuss the provident dispensary scheme, which was alluded to in THE LANCET of last week is calculated to do a great deal of good. If its promoters can succeed in substituting it for the many clubs which still exist, and which give little or no satisfaction either to the members or their medical attendants, they will have done an excellent work. The history, however, of most provident dispensaries shows that they are most successful in small towns or in certain districts of large towns. Whether one of so comprehensive a character as shall comprise the whole of Liverpool be feasible remains to be seen. It should be stated, however, that our medical charities are neither too numerous nor more abused than those of other cities. If anything, Liverpool has been somewhat slack in recognising the necessity for hospitals. The Royal Infirmary was not established until the middle of last century, and when rebuilt in 1824 only contained 200 beds, though the population in 1831 was 205,000. It remained the only hospital till 1834, when the Northern Hospital was established. In 1841 the Southern Hospital was founded, the population of the borough and neighbourhood being then 286,000. At none of these three hospitals are out-patients seen, except casualties and former in-patients; while at the three Dispensaries, the Eye and Ear Infirmary, the Infirmary for Children, and the Hospital for Women, the patients' pence amount to a very considerable sum. The Stanley and Bootle Hospitals are of comparatively recent date, and seeing that the population of Liverpool and its suburbs now reaches nearly 600,000, our hospitals cannot be said to be in excess of what is reasonably required, nor disproportionate with those of other cities.

THE INFIRMARY FOR CHILDREN.

At the annual meeting of the Infirmary for Children, held on the 26th inst., it was stated that the number of in-patients during 1885 was 1012, the out-patients were 9577, and the attendances 27,131. The drainage having been found to be defective, this was rectified at a cost of £857. Although every economy consistent with efficiency was practised, the financial position of the charity was such as to cause anxiety to the committee, the depression of trade seriously affecting the receipts, while the expenditure had been increased.

PROPOSED REMOVAL OF ANOTHER CITY CHURCHYARD.

Notice has been given by the authorities of their intention to remove a portion of St. Thomas's Churchyard for the purpose of city improvements. When first erected this church and churchyard were situated outside the city, in a lane leading to Toxteth Park, still called Park-lane. Now it is surrounded by buildings, many of the most squalid description; the churchyard is a dreary waste of tombstones, the receptacle for stray rubbish, and as unsightly as a burial-ground can be. It was closed in 1854. Most of the interments are in vaults.

THE MERSEY TUNNEL.

The new tunnel under the River Mersey, which will be open to traffic on the 1st prox., will be a great boon to all who are now compelled to cross the river in steamboats in foggy or tempestuous weather. Most welcome will it be to persons who are specially subject to sea-sickness and those who have delicate chests. Many a severe illness and even death might be traced to crossing over in a fog. It is very gratifying to add that, by adopting all the most recent improvements in tunnel ventilation, the air of the new tunnel is stated to be remarkably clear.

Liverpool, Jan. 27th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE HOSPITAL SUNDAY.

THE final official lists of the collections made on behalf of the Newcastle Hospital Sunday Fund in October last have been published. The amount realised from places of worship was £1974 19*s.* 4*d.*, as compared with £1888 9*s.*, in the previous year. The sum collected in manufactories, collieries, and other works amounted to £1437 5*s.* 9*d.*, the amount of the corresponding list of 1884 having been £1474 18*s.* 11*d.* The total product of the two sources of revenue in October last was £3412 5*s.* 1*d.*, as compared with £3363 7*s.* 11*d.* in 1884. There has thus, it will be seen, been a slight falling off in the amount derived from workpeople, but with the increased sum obtained from places of worship there is altogether an improvement to the extent of £48 17*s.* 2*d.*

POISONING BY LUCIFER MATCHES.

Since I last wrote another case of attempted suicide by steeping lucifer matches and drinking the infusion has been before our magistrates. The girl recovered, but has been in a very weak state for some time. She was discharged after a sharp reprimand. A fatal case, however, has just taken place in South Shields from the same cause, and an inquest has been held. It appears that the young woman, aged twenty-four, after some misunderstanding with her sweetheart, steeped thirty boxes of matches in water and drank the fluid. Dr. Young deposed to having seen the deceased, who exhibited the usual symptoms of poisoning by phosphorus—viz., burning pain in the chest and stomach, great thirst, and exhaustion. The vomit smelt strongly of phosphorus, and was luminous in the dark. The coroner deprecated the practice of the press publishing full reports of such cases, thus giving love-sick girls a cheap and easy receipt for destroying themselves.

HALFPENNY BREAKFASTS.

The head master of the Board School at Wallsend (Mr. Tocher), seeing so much distress about, and that many of the children attending his school were badly prepared to face the lessons of the day for want of sufficient food at home, and being, it is said, a firm believer in oatmeal, once the chief of "Scotia's food," determined to do something on his own account without waiting for "a committee." So he ordered a good supply of oatmeal from a mill in Berwickshire of the finest quality. The cooking operations commence at 6·30 A.M., and the porridge is allowed to boil for fifty minutes, and is cooled and ready for serving out at a quarter past eight. Each child is supplied with about a pint of porridge—more or less according to size and appetite—and a little more than half a gill of good skimmed milk. About 120 children are thus receiving breakfasts at a cost of about one halfpenny each, and in most cases they are given free. In times gone by oatmeal was also the staple food of the north of England; it will be curious if it comes again into use. Its value as regards nutrition for children is beyond dispute; high wages have conduced to a high-class, though not better, food for the children of our working classes.

Newcastle-on-Tyne, January 26th.

EDINBURGH.

(From our own Correspondent.)

THE CHAIR OF AGRICULTURE.

AT a recent meeting of the Highland and Agricultural Society it was decided to renew the grant of £150 per annum towards the endowment of the University Chair of Agriculture. For several months this grant has been in abeyance pending the result of a discussion upon the subject of agricultural education generally. The chair has in the past been maintained by University endowments, by an annual Government grant, and by the grant from the Society already mentioned. The committee of the Society, to whom the question of educational arrangements was handed over, have not yet been able to bring forward any definite scheme for adjusting the matter. In the meantime, the Society has been approached on two sides: by the Uni-

Digitized by Google

versity authorities, who request a continuance of the old arrangement, for a time at least, till a new Universities Bill may deal with the larger question of agricultural education; and by Sir Francis Sandford, Under Secretary for Scotland, who represented that the Government were prepared to continue their grant in the annual estimates only on condition that the Society's grant was also continued. This latter intimation settled the matter; the Society at once agreed to continue their endowment. The result is satisfactory; for not only would a contrary conclusion have probably signified the abolition of the chair, but would have seriously interfered with the prospects of the newly appointed professor, whose class has already been greatly increased, and whose energetic treatment of his subject bids fair to make the course of lectures one of the most complete which the University offers.

THE FEVER HOSPITAL AND CLINICAL INSTRUCTION.

The Public Health Committee, who are charged with the administrative arrangements of the City Fever Hospital, have brought in a report to the Town Council in which they propose a settlement of the questions which have been recently discussed as to the propriety of appointing clinical lecturers on fevers and admitting students to the use of the hospital wards. They propose that a competent visiting physician should in the first place be appointed for a term of three years; and that he should be capable of giving instruction to any students who may attend, should it be decided to allow such attendance. The committee do not in the meantime propose to attach any emolument to this post, as they believe there will be little difficulty in obtaining the services of a thoroughly qualified physician who will be prepared to discharge his duties gratuitously. Should the teaching of students be superadded to his visiting duties, some other arrangement would be submitted. Till the appointment is made the committee reserve further suggestions as to clinical teaching, in the hope that when this point is beyond the range of controversy the various medical bodies will combine in suggesting some comprehensive scheme for conducting the instruction which will satisfy the wishes of all parties, both teachers and students alike. While admitting the importance of this branch of education in the training of medical men, the committee consider it an imperative duty to see that these arrangements in no way interfere with the primary object of the institution—the careful treatment and nursing of its inmates; and they show no inclination to further arrangements which might make this course of instruction a compulsory adjunct to either the University or extra-academic curriculum.

AMBULANCE INSTRUCTION FOR THE POLICE.

A project is at present under the consideration of the Town Council by which instruction in first aid to the injured is to be given to the whole of the city police force by members of St. Andrews Ambulance Association. A commencement was made in this direction last year, when Dr. Skene Keith trained a small number of the force in the elements of ambulance drill; and so good were the results of this training that it is now hoped that the whole body of police may be instructed in the same system, and rendered capable of supplying efficient aid in those cases of emergency which occur from time to time in the streets.

ROYAL PHYSICAL SOCIETY.

At the January meeting of this Society, Professor Turner, the newly-elected President, inaugurated the session by some introductory remarks on the present position and future prospects of the Society, which he considered satisfactory. An obituary notice of the late Dr. W. B. Carpenter was read by Professor Cossar Ewart. A number of communications followed, amongst them one by the President on the Distribution of the Bottle-nosed Whale and its occurrence in Scottish Waters, which was illustrated by a series of charts and diagrams.

Edinburgh, Jan. 27th.

PARIS.

(From our own Correspondent.)

DEATH OF DR. JULES GUÉRIN.

ONE of the most remarkable characters of the profession of this country has just passed away in the person of Dr. Jules Guérin, who died suddenly at Hyères, whither he had gone to recruit his health, which had been declining for some time. Dr. Guérin left Paris on the 14th inst. for the above-named place. He was so weak that he had to be carried from the railway station to the train in a chair. He suffered from disease of the heart, complicated with an intestinal affection, which was contracted some years ago. Travelling by easy stages, on his arrival at Hyères, and being accompanied by Madame Guérin, he felt very much better, so much so that he thought of soon returning to Paris; but on Monday, the 25th inst., he had an attack of syncope, for which he had to take to his bed, and expired a few hours afterwards. Dr. Guérin was the type of a general practitioner of the old school, but he had a greater predilection for surgery than for medicine, and in the early part of his professional career he distinguished himself as an orthopædist. He was the author of several works of great value, and those on teratology are amongst the most remarkable ever written on the subject. He was very firm in his opinions, which, whether right or wrong, he maintained with great tact and ingenuity. For instance, to the day of his death his theory as to the unique nature of cholera was unshaken, on which subject he only lately distinguished himself in the debates that took place at the Academy of Medicine. He was about eighty-five years of age and one of the senior members of the profession in Paris, having taken his degree in 1826. He had been a member of the Academy of Medicine since 1842 in the section of Medical Pathology. He was also a Commander of the Legion of Honour.

OPERATIONS BY M. TILLAUX.

On entering the operating theatre at the Hôtel Dieu last week I found M. Tillaux performing an operation. It was, however, impossible to see what he was doing, as the operating table was completely surrounded by his assistants and other visitors, and were it not for a few *vivâ-voce* explanations, the spectators could have formed no idea of what was going on. What is said here may be applied to all the French operating theatres. M. Tillaux's operation consisted, as he afterwards explained, in the removal of a fibro-myxomatous tumour, which occupied the naso-pharyngeal region, and was about the size of a small hen's egg. It occurred in a young provincial coachman, aged twenty-four years, and had been seven years reaching that size. The palate was divided to get at the tumour, the pedicle of which was found attached to the vomer. There was scarcely any hæmorrhage. Three silver wire sutures were put in. The patient bore the operation very well. No anæsthetics were employed, but the local application of a solution of cocaine prevented the patient from suffering any pain during the section of the palate, which was performed in the median line from the osseous portion through the soft and unattached parts. I saw the patient on the 24th inst.—that is, a week after the operation; the sutures had been removed, and the patient was ready to return to his native village, full of gratitude, as he had not been able to breathe so freely for some time. On the same day M. Tillaux drew off about three litres of a clear colourless fluid from a cyst in the liver of a man thirty-five years of age. The operation was performed with a Dieulafoy's aspirator, and the patient left the hospital three days after, feeling quite well and experiencing no inconvenience from the operation. One of the lads who underwent Estlander's operation about four months ago at the Hôtel Dieu, and whose case was reported in THE LANCET of Oct. 10th last, was lately presented to the Société de Chirurgie by M. Bouilly, the operator, who stated that the cavity containing the purulent matter was filling up; but as the patient was not recruiting his strength as quickly as could be desired, he was allowed to return to his home. The other patient, who was operated on by M. Tillaux, and whose case was also reported at the same time, is still in the hospital, and it strikes me that he, too, should be sent away, as his health is not by any means improving, though there is now scarcely any discharge from the chest.

BANQUET IN HONOUR OF DR. MATHIAS DUVAL.

A very interesting entertainment in the form of a banquet was offered last week to Dr. Mathias Duval on the occasion of his appointment to the Professorship of Histology at the Paris Faculty of Medicine. The banquet was presided over by Professor Gavarret, Inspector-General of the Medical Schools of France, who had opposite to him at the table Professor Béclard, Dean of the Faculty. Many interesting speeches were made on the occasion, and referred par-

Digitized by Google

ticularly to the attainments of the guest as an anatomist, physiologist, and histologist of the highest order. One of the speakers in his enthusiasm spoke of histology as being a science peculiarly French, thus ignoring what has been done in other countries in that direction.

M. PASTEUR.

Owing to the numerous applications that are made to M. Pasteur for his remedy against hydrophobia, he is receiving liberal donations from all quarters to enable him to meet the expenses incurred by him, as most of the applicants belong to the poorer classes, and he is obliged to keep them during the time they are under treatment.

THE RIGHTS OF "OFFICIERS DE SANTÉ."

Till now the "officiers de santé" were not allowed to practise out of the department in which they obtained their diploma. A proposition has just been laid before the Chamber of Deputies to abrogate this law, and to allow them to practise without any restriction in any part of the French territory without any other authorisation, or without even obtaining a fresh diploma. This is considered a crying injustice, as by this means they will be placed on the same footing as the doctors who have to pass a superior examination, and consequently pay higher fees for their degrees.

Paris, Jan. 27th.

BERLIN.

(From our own Correspondent.)

SECRET REMEDIES.

THE Berlin Committee for the "Suppression of the Nuisance of Secret Remedies" have decided to present a memorial to Prince Bismarck, with the following propositions: 1. In place of the Imperial ordinance of Jan. 4th, 1875, there ought to be issued one which assigns the preparation, and the keeping and offering for sale, of all kinds of medicaments, inclusive of secret remedies and pharmaceutic specialties for sanitary purposes, in retail, exclusively to the apothecaries' shops. 2. For the restriction of the sale of secret remedies in the apothecaries' shops there ought to be instituted an Imperial board, acting as a technical central office, having the function to examine and test every secret remedy before permitting it to be sold; to fix the price of such remedy; and to determine whether the drug or compound may be issued to the public otherwise than in the form of a physician's prescription. 3. To prevent an inundation of the market with foreign secret remedies and pharmaceutical specialities, it is suggested that they should be subjected to a duty *ad valorem*.

DISINFECTION BY THE SALT-WATER STOVE.

A year ago Professor A. Dobroslawin of St. Petersburg published a preliminary communication on a portable disinfecting stove constructed by him, which acted through over-heated air. The author obtained the high temperature simply by the use of solutions of common salt instead of plain water. To produce a higher temperature some different salts may be employed. In 100 parts of water, 41·2 parts of common salt gave the boiling-point at 108·4° C.; 61·5 parts of nitrate of ammonia, gave it at 121·0°; 205·0 parts of carbonate of potash, 135·0°; 325·0 parts of chloride of calcium, 179·5°; 88·9 parts of chloride of calcium, 114·2°. The stove requires from 40 to 50 litres of the solution, and fills with a solution of common salt after two or three hours. After four hours' working it must be refilled. To prove the effect on micro-organisms, silk threads saturated with the spores of bacillus subtilis were submitted to the stove, and were completely killed, after remaining three or four hours in the stove, at 102° to 104° C. The price of the apparatus is 250 roubles (£25), to be procured through the St. Petersburg Metallfabrik.

Berlin, Jan. 21st, 1886.

ST. LEONARDS CONVALESCENT HOME FOR CHILDREN.—The annual meeting of the subscribers to and governors of this Home was held on the 20th inst. In the report it was stated that the institution was doing fairly well, and that during the year 640 children had been admitted to its benefits, of which came from London and its suburbs, 99 [illegible], 19 from Kent, and 28 from Middlesex.

ROYAL COLLEGE OF PHYSICIANS.

AN ordinary Comitia of the College of Physicians was held on the 28th inst., Sir W. Jenner, Bart., President, in the chair. The President drew attention to the fact that in addition to the case considered at the last Comitia, three charges of unprofessional conduct on the part of members and licentiates had been investigated by the Censors' Board, proving, Sir William maintained, that the College was active in vindicating the honour of the profession.

The President nominated Dr. Pavy to deliver the Harveian Oration and Dr. Dreschfeld to give the Bradshawe Lecture this year. The Treasurer announced that the late Dr. Gavin Milroy had bequeathed the sum of £2000, together with certain manuscripts and books, to the College, the money to be devoted to founding a lectureship in State Medicine and Public Hygiene.

Three gentlemen were admitted to the membership, and the licence was granted to 86 successful candidates at the last examination.

Dr. P. W. Latham, Dr. Playfair, Dr. Ringer, and Sir J. Fayrer were elected on the Council; and Drs. Stone and Duckworth were appointed examiners for the Murchison Scholarship.

The quarterly report of the Finance Committee was received and adopted. The annual report of the examiners was read, from which it appears that during 1885 1136 candidates presented themselves for the first examination for the licence, of whom 633 were approved; and 394 for the final examination, of whom 242 were approved. These figures include those who have been examined under the new scheme, and the rejections were in one or more subjects of the examination. A report from the Building Committee was received. It stated that the works connected with the new examination hall were proceeding satisfactorily, and proposed that the laying of the first stone of the buildings should be marked by a public ceremony.

MEDICAL NOTES IN PARLIAMENT.

Overhead Wires.

IN the House of Commons on the 25th inst., in reply to Sir H. Tyler, Lord J. Manners stated that his attention had been drawn to the failure of telegraph wires during the recent snowstorm, and that no case of accident to any human being had been caused by the wires belonging to the Post Office. The policy of the Post Office for many years past has been to substitute underground for overhead wires in London, and also in other large cities, wherever the extra expense involved could be justified. The mileage of postal telegraph wires in the metropolis on the 31st of December was 9832 miles, of which 9005 miles, or about 11-12ths, were underground wires. In the eastern central and western central postal districts, which comprise the half of the metropolis, there were only 44 miles of overhead wires the property of the Department.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Board of Examiners on the 21st inst.:—

Bertill, Alfred, Oltom.
Bridgewood, John Francis, Stafford.
Brown, Frederick Nathaniel, Chobham.
Christopherson, Cecil, L.S.A., Blackheath.
Clark, Francis William, East Croydon.
Creagh, Arthur George Mellefont, L.S.A., Ballinrollin.
Evans, Oliver Conrad Penrhys, L.R.C.P. Lond., Hadlow, Kent.
Fraser, Paul Wilkes, Wolverhampton.
Hassard, Edward Moresby, Hoddesdon.
Hawkins, Frank Sidney, Bristol.
Ireland, Charles John, Amwell-road.
Pisani, Lionel John, L.S.A., Upper Norwood.
Robinson, Arthur William, Longleat.
Williams, Hugh Lloyd, Waenfawr, Carnarvon.
Young, Charles Wheeler Forrest, L.S.A., Clapham-common.

Admitted on the 22nd inst.:—

Bennett, Frederick Thomas, L.S.A., Denmark-hill.
Brown, Edward Vipont, Tufnell-park.

Candler, Wallace Harry Charles, L.R.C.P. Lond., Lee.
Darlington, Alfred Naylor, L.S.A., Birmingham.
Déqué, Laurent, L.R.C.P. Lond., Derby.
Evill, Frederick Claude, L.R.C.P. Lond., Worcester-park.
Greenwood, George Spencer, Ossett, Yorks.
Hodge, Sydney Rupert, L.R.C.P. Lond., Hornsey-lane.
Holderness, John Cautley, Bishops Wilton, Yorks.
Horner, Charles, Julian, Walthamstow.
Le Quesne, Ferdinand Simeon, L.S.A., Brighton.
Morgan, Frederic James, L.R.C.P. Lond., Junction-road.
Okell, John Bathurst, L.R.C.P. Lond., Chester.
Pollard, Charles, Wade Bridge, Cornwall.
Roughton, John Paul, Kettering.
Russell, George Herbert, L.R.C.P. Lond., Barking-road.
Snow, Lionel Mason, King Henry's-road.
Sturdee, Alfred Hobart, Southsea.
Symes, George Dickinson, Dorchester.
Tonks, Henry, Knowle, Warwickshire.
Williams, Lionel Henry, Clifton, Bristol.
Williams, Thomas Henry, L.R.C.P. Lond., Seymour-street.
Wordsworth, William John, Harley-street.
Wright, Alfred, Cape Town.

Admitted on the 25th inst.:—

Barber, Percival Ellison, L.R.C.P. Lond., Sheffield.
Birt, Joseph, Brighton.
Burghard, Frederic François, Brixton.
Castle, Richard Feild, Delamere-crescent.
Combes, Reginald Hare, L.R.C.P. Lond., New South Wales.
Crisp, John, L.R.C.P. Lond., Kennington-park-gardens.
Gardner, William Thomas, L.R.C.P. Lond., Hampstead.
Griffith, Christopher Arthur, Finsbury-park.
Harrison, Sidney Hope, Tamworth.
Holt, Joshua, Leeds.
Hubbard, James Printer, Dudley.
Smith, Robert Gillies, Durham.
Smith, John Anderson, Hull.
Ward, John Oddy, L.S.A., Crossgate, near Leeds.
Warde, Arthur Waldemar Brougham, Yalding.

Admitted on the 26th inst.:—

Bond, Barnabas Mayston, L.R.C.P. Lond., Hastings.
Dickinson, Charles, Sloane-street.
Ewens, George Francis William, West Hammersmith.
Hope, George, L.R.C.P. Lond., Ventnor, Isle of Wight.
Hulke, Frederick Backhouse, L.R.C.P. Lond., Deal.
Pollard, George Frederick, L.S.A., Falmouth-road.
Totsuka, Kankai, L.R.C.P. Lond., Tokio, Japan.
Williams-Freeman, John Peere, M.B. Durham, Southampton.
Wood, Arthur Thorley, Melton Hall, Suffolk.

Admitted on the 27th inst.:—

Collingwood, Frederick William, L.R.C.P. Lond., Manor-road.
Crosse, William Henry, L.S.A., Terrington, Norfolk.
Evans, Evan, M.B. Cantab., Dorchester-place.
Francis, Harry Arthur, L.R.C.P. Lond.
Gifford, George Taylor, L.S.A., Manchester.
Harris, Percy Reeves Trier, L.S.A., Amhurst-park.
Mariette, Ernest Paul Alphonso, L.S.A., St. Stephen's-square.
Morris, Colin Dwight, L.S.A., Philpot-street.
Parsons, Frederick Gymer, L.R.C.P. Lond.
Stadden, Walter Joseph, L.R.C.P. Lond.
Staveley, William Henry Charles, L.R.C.P. Lond.
Wacher, Sidney, L.R.C.P. Lond.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise, on the 21st inst.:—

Beer, Louis Edward Simon, Hampstead-road.
Parker, Charles Arthur, Claxby, Alford, Lincolnshire.
Pound, Clement, Odiham, Hants.
Toogood, Frederick Sherman, Manor-park-road, Willesden.

The following passed the examination in the Science and Practice of Medicine, and received certificates to practise:—

Creagh, Arthur George Mellefont, Ballenvollin, county Cork.
Owen, Samuel Walshe, M.R.C.S., Landroft-road, East Dulwich.

Mr. Oliver Pemberton and Mr. Lawson Tait have been elected trustees of Sir Josiah Mason's Science College.

DURING the past year £1015 has been collected by the Cardiff Infirmary Saturday Fund Committee.

THE annual meeting of the Salisbury and South Wilts Provident Dispensary was held on the 16th inst., when a highly satisfactory report was presented by the committee.

AT the annual meeting of the Council of the Metropolitan Hospital Sunday Fund, which was held in the Mansion House on the 22nd inst., committees and officers for the year 1886 were elected.

THE Vice-Provost of Trinity College and the Astronomer Royal, Ireland, each received the honour of knighthood on Monday last, at the hands of his Excellency the Lord Lieutenant.

AT a general meeting of the members of the Hospitals' Association, on the 27th inst., a deputation was received from the British Medical Association, on the hospital out-patient question. The views of the visitors having been stated, a lengthy discussion followed.

AT a meeting of the Sanitary Committee of the Leeds Corporation on the 25th inst., rules for the regulation of the various cowsheds, milkshops, and dairies in the borough were passed.

CARDIFF MEDICAL SOCIETY.—The following gentlemen have been elected office-bearers for 1886-87: President: Dr. William Thomas Edwards, President of the British Medical Association. Committee: A. P. Fiddian, M.B., C. T. Vachell, M.D., A. Plain, M.B., W. M. H. Evans, M.R.C.S. Hon. Secretary: T. Garrett Horder.

VICTORIA UNIVERSITY, MANCHESTER.—The following appointments have recently been made: Brackenbury Professorship of Physiology: William Stirling, M.D., D.Sc., Regius Professor of the Institutes of Medicine in the University of Aberdeen. Lectureship in Medical Jurisprudence: John Dixon Mann, M.D., M.R.C.P.

NEW INFIRMARY FOR PADDINGTON.—On Tuesday a new infirmary for the use of the sick poor of Paddington was opened for the reception of patients. The building occupies a site adjoining the workhouse in Harrow-road, is provided with 284 beds, and has been erected at a cost of something like £50,000.

WESTMINSTER HOSPITAL.—On Thursday and Friday evening last an entertainment was given to the nursing staff and patients of this hospital. The programme comprised a short extravaganza, entitled "A Romance under Difficulties," which was played by the resident medical officers, and was the source of much hilarity. The decorations were very ornate and tasteful.

AT the annual meeting of the subscribers to and friends of the Pendlebury Hospital and Dispensary for Sick Children attention was called to the practice, common among the poorer classes, of insuring the lives of their children, and it was stated that 75 per cent. of the children dying at the institution were in a club. Clubs in which an infant of a few days old may be insured for any sum up to £6 offer a premium on neglect and carelessness.

CITY DISPENSARY.—The ninety-seventh annual meeting of the governors of this institution was held on the 20th inst. The number of patients on the books on Jan. 1st, 1885, was 1296, and 13,476 were admitted during the year. The total receipts amounted to £1825, and the expenditure to £1404, leaving a balance of £421 in the hands of the treasurer, against £692 at the corresponding period of last year.

THRIFT AND THE WORKING CLASSES.—Dr. Robert Rentoul of Liverpool will read a paper to the Metropolitan Provident Medical Association on Thrift and the Working Classes. We believe that Dr Rentoul intends describing "compulsory insurance against sickness and accident as it now exists in Germany," also Canon Blackley's "compulsory national insurance." The Association meets at 5, Lamb's-conduit-street, and the chair will be taken at 4.30 A.M. by W. Boustield, Esq.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—On Wednesday, January 13th, the quarterly Court of the Directors of the above Society was held, Sir Henry Pitman, Vice-President in the chair. Grants amounting to £1338 were given to 63 widows, 9 orphans, and 3 orphans on the Copeland Fund. The expenses of the quarter were £66 17*s*. One member was elected, and the death of one reported. The death of a widow in receipt of £50 per annum was announced. There were no fresh applications for relief. The Christmas present, £172 10*s*. had been distributed in December last.

PRESENTATIONS.—Mr. J. C. Smith, medical officer at the workhouse of the parish of Great Yarmouth, was on the 12th inst. presented, on behalf of the Poor-law officials of the parish, with a pair of bronze figures and a congratulatory address, commemorative of the attainment of the fiftieth anniversary of his wedding day.—Mr. C. Lowsley, who recently resigned his post as medical officer to the Reading Dispensary, has been presented with a clock and pair of bronze ornaments by upwards of 600 of his former patients.—On the 23rd inst. Mr. R. Prosser, L.R.C.P., of Bromsgrove, was presented with a dessert service of solid silver as a token, on the attainment of his fiftieth birthday, of the esteem in which he is held by his numerous friends in the town in which he resides.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BRABAZON, HENRY MOORE, M.B., B.Ch.Dub. Univ., has been appointed House-Surgeon to Sir Patrick Dun's Hospital.

CHAMPNEYS, FRANCIS H., F.R.C.P., has been appointed Acting Physician to the General Lying-in Hospital, York-road, Lambeth, vice Williams, resigned.

CORBOULD, HENRY F., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Infirmary of the Wandsworth and Clapham Union.

ENTAGE, EDMUND W., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District of the Holsworthy Union.

HERMAN, G. ERNEST, F.R.C.S., F.R.C.P., has been elected Physician to the General Lying-in Hospital, York-road, Lambeth, vice Champneys.

HOGBEN, EDGAR, M.B., has been appointed Physician to Out-Patients to the Queen's Hospital, Birmingham.

LANGHORNE, T. GRANT, M.R.C.S., has been appointed Resident Medical Officer to the Eccles and Patricroft Hospital, Eccles.

WILLIAMS, JOHN, M.D., F.R.C.P., has been appointed Consulting-Physician to the General Lying-in Hospital, York-road, Lambeth.

Births, Marriages, and Deaths.

BIRTHS.

COGAN.—On the 21st inst., at Gibraltar, the wife of Surgeon-Major M. Cogan, Medical Staff, of a son.

DAUNT.—On the 24th inst., at Pierpoint, Lindfield, the wife of Elliot Daunt, L.R.C.P.Lond., M.R.C.S., of a son.

GOULD.—On the 23rd inst., at 16, Queen Anne-street, Cavendish-square, the wife of A. Pearce Gould, F.R.C.S., of a son.

HOPKINS.—On the 23rd inst., at Liverpool-gardens, Worthing, the wife of Surgeon-Major Nathaniel Hopkins, of a son.

STEVENSON.—On the 21st inst., at Camberwell-grove, Denmark-hill, the wife of Leader Stevenson, M.D., of a son.

MARRIAGES.

AINSLEY—HILL.—On the 14th inst., at St. Stephen's, Westbourne-park, Thomas George Ainsley, M.B., M.R.C.S., of Hartlepool, to Wilhelmina Caroline Hill, of Albrighton, Shropshire, daughter of the late H. T. Hill, Esq., of Notting-hill.

CONOLLY—RENWICK.—On the 20th inst., at St. Mark's, Notting-hill, Stephen Fullom Conolly, M.R.C.S. and L.R.C.P.Edin., third son of the late Captain Conolly, Surveyor-General's Department, War Office, to Helen Elizabeth, daughter of General Renwick, R.E.

JERAM—SMITH.—On the 25th inst., at Christ Church, Ealing, W., James William Jeram, L.R.C.P.Ed., L.R.C.S.Ed., of Hambledon, Hants, eldest son of George Jeram, Esq., of Havant, Hants, to Annie Caroline, daughter of the late Captain Charles Mayvore Smith, Madras Native Infantry, and granddaughter of the late Colonel Smith, of Plympton, Devon, and Charles G. E. Ford, Deputy Surgeon-General, Madras Army.

THOMAS—LITTLE.—On November 4th, at St. Andrew's, Lutwyche, Walter Duncan Thomas, M.B.Lond., of Bundaberg, Queensland, second son of the late Benjamin Thomas, F.R.C.S., of Llanelly, to Leila Boyle, third daughter of Robert Little, of Whyteleaffe.

YELLOWLEES—WILLIAMSON.—On the 20th inst., at Bellmoir, Bridge of Allan, N.B., by the father of the bride, D. Yellowlees, M.D., of Gartnavel, Glasgow, to Federata, eldest daughter of the Rev. H. M. Williamson, of Belfast, and granddaughter of the late Major James Robert Robertson, of Cray, Perthshire.

DEATHS.

BOWMAR.—On the 23rd inst., at his residence, St. Martin's, Leicester, Charles Bowmar, M.R.C.S., aged 83.

BROOKS.—On the 24th inst., at Henley-on-Thames, Oxon, James Henry Brooks, M.R.C.S., in his 80th year.

COWEN.—On the 24th inst., (his 69th birthday), at Drayton-park, N., Surgeon-General Henry Lionel Cowen, Army Medical Department (retired).

CURRY.—On the 21st inst., at Barnstaple, suddenly, William Curry, F.R.C.S., L.S.A.Lond., J.P. for the county of Devon, second son of the late Admiral Curry, C.B., aged 77.

DA SILVA.—On Dec. 25th, 1885, at Ghadichi Bhownugra, Kathiawar, India, Pascal M. Da Silva, M.R.C.S.Eng., L.R.C.P.Lond., L.S.A.Lond., Surgeon-in-Charge, Bhavnager-Gondal Railway, aged 34.

POTHECARY.—On the 23rd inst., at Clyde-road, Addiscombe, Charles Pothecary, M.R.C.S., aged 72.

SMITH.—On the 22nd inst., at 2, Stanhope-terrace, Gloucester-gate, N.W., Herbert Ross (Bertie), youngest son of Walter Smith, M.D., M.R.C.P.Edin., aged 11 years.

SUTTON.—On the 20th inst., at Hoylake, Cheshire, John Maule Sutton, M.D., J.P. and D.L. for county Pembroke, aged 56.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, February 1.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesdays, same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Prof. H. S. Hele Shaw: Friction (Cantor Lecture).
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communication by Mr. Storer Bennett.—Mr. J. Bland Sutton: Dental and Oral Cases in Animals.—President's inaugural address.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Jonathan Hutchinson, F.R.S.: Some Moot Points in the Natural History of Syphilis (Lettsomian Lecture).

Tuesday, February 2.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. R. Stuart Poole: Naucratis.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Specimens of Tumours of the Brain and its Membranes will be exhibited by Dr. Ashby, Dr. Barlow, Dr. Beevor, Mr. Butlin, Dr. Chaffey, Dr. Goodhart, Dr. Hadden, Dr. P. W. Macdonald, Dr. G. Ogilvie, Dr. Ord, Mr. D'Arcy Power, Mr. Peeke Richards, Dr. Saundby, Dr. F. Taylor, Dr. Charlewood Turner, and Dr. Samuel West. Dr. Hale White will show Specimens of Thinning of the Skull from Cerebral Tumours. Microscopical Specimens will be on view at 8 P.M.

Wednesday, February 3.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesdays and Thursdays, 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department, Tuesdays and Fridays, 9.30 A.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.
SOCIETY OF ARTS.—8 P.M. Mr. George Simonds: Artistic Bronze-Casting.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Annual Address by the President (Dr. Potter). Specimens will be shown. Mr. Knowsley Thornton: A case of Removal of both Ovaries during Pregnancy.—Dr. Lewers: A case of Circumscribed Sarcoma of Uterus and Vagina.—Dr. Matthews Duncan: On Contraction, Inhibition, and Expansion of the Uterus.

Thursday, February 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Prof. W. Chandler Roberts-Austen: Metals as affected by Small Quantities of Impurity.
PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. G. A. Heron: How it is Shown that Living Things cause some of the Diseases of Man. The lecture will be illustrated by microscopical specimens.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Dr. D. B. Lees: The Neurotic Treatment of Catarrh.—Mr. Shirley Murphy: Animal Vaccination.

Friday, February 5.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Percy Dunn: (1) A Morbid Growth involving the Right Ligament and Ovary, causing Complete Obstruction of the Intestinal Canal; (2) Chronic Suppuration of the Lung following Pneumonia.—Dr. Campbell Pope: Large Urinary Calculus passed per urethram.—Mr. Hurry Fenwick: Photographs of twelve cases of Extroversio Vesicæ.—Mr. Bruce Clarke: On Abdominal Exploration.—Dr. Herringham and Mr. Edmonds: A case showing the results of Infantile Palsy.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—8 P.M. Clinical Evening. Mr. Power and Mr. Juler.
ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Mr. T. Pridgin Teale: The Principles of Domestic Fireplace Construction.

Saturday, February 6.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION OF GREAT BRITAIN.—3 P.M. Mr. Archibald Geikie The History of Volcanic Action in the British Isles.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

QUACKERY AND ITS PUNISHMENT IN HOLLAND.

A ROTTERDAM jeweller, who has been for some time past carrying on the trade of "cancer curer," which he seems to have found much more profitable than that to which he was brought up, has found to his chagrin that the Dutch laws do not allow of the perfect freedom in the treatment of the human body which is doubtless considered as an important part of the liberty of the subject by the whole confraternity of charlatans. Had his impostures been carried on in this country, it is questionable whether he could have been successfully prosecuted at all, and under the most favourable circumstances he would only have been compelled to disgorge a few pounds of his ill-gotten gains by way of a fine. The Dutch court, however, marked its sense of the gravity of offences of this character by sending him to prison for fifteen days.

Justitia.—We regret we are unable to answer the questions. Probably the information might be obtained from the publishers.

QUINQUENNIAL CENSUS.

To the Editor of THE LANCET.

SIR,—I was extremely pleased to see in your issue of Jan. 16th (p. 122) an annotation advocating the propriety of a quinquennial census. It is a matter that has long pressed on my mind, and I have spoken of it in high political quarters, but have been told that the great argument against it is its expense. My feeling is that the advantage we should derive would far exceed the expense. Statistics are sometimes said to be very misleading. This can only be true if the statistics are false, and our great concern is in every case to prevent this. The circumstance of the immigration of our populations as affecting the census of towns, in addition to the natural excess of births over death, is a matter too plain for more than mention, but its effect in falsifying the official death-rate tables is very serious in a number of cases. I am informed that the quinquennial census has already been adopted in Germany—a circumstance worthy of consideration in the argument.

I am, Sir, yours obediently,

Bideford, Jan. 20th, 1886. JOHN THOMPSON, M.D.

TOUTING FOR PATIENTS.

To the Editor of THE LANCET.

SIR,—Can you tell me if it is in accordance with professional etiquette for one practitioner to send round an agent to call at the doors of other practitioners' patients to ask them to join his "club" (not a charitable one) for a weekly payment of 2*d*. I am, Sir, yours truly,

Jan. 23rd, 1886. G. G. B.

*** We need scarcely say that such a procedure is highly unprofessional. —ED. L.

RENAL SURGERY.

Mr. Clement Lucas writes that the operation for total suppression of urine performed by him on a patient of Mr. Atkins of Sutton, previously noticed in THE LANCET, has proved completely successful. The wound healed soundly, and the single kidney, relieved of the stone which blocked its outlet, is working as well as before the operation, whilst the patient's general health is quite restored. Thus a new way of saving life in particular instances has been successfully pioneered. Mr. Lucas explored a kidney for calculus on Jan. 19th in a young gentleman who had been under the care of Dr. Theard, and for some time under the observation of Professor Humphry at Cambridge, for frequent paroxysmal attacks of acute pain in the region of the left kidney, which had been ruptured two years before. No stone was found, but a cicatricial adhesion between the colon and kidney. On Jan. 22nd Mr. Lucas operated in Guy's Hospital on a patient of Dr. Boyce of Maidstone, for a dilated strumous kidney, which he drained through the loin. These patients are progressing favourably.

Enquirens.—The course is undoubtedly legal. The risk attending it must be judged of by our correspondent.

"PARALYSIS AGITANS" AND "CEPHALALGIA."

To the Editor of THE LANCET.

SIR,—In reply to "Inquirer" and Mr. Hunt, whose letters appeared in your issue of Jan. 9th, p. 94, I beg to recommend a medicine which I have found of great service in similar cases. It is the biniodide of mercury. The descriptions given point, of course, in both cases to meningeal mischief; in the former over the motor centres of the vertex, and in the latter at the base of the brain. I prescribe the biniodide in a mixture, as follows:—Solution of bichloride of mercury (P.B.), ℥i–℥iss; iodide of potassium, ʒ ss—℈ ij; infusion of gentian or of calumba to ℥ viii; half an ounce to be taken every three or four hours. In "Inquirer's" case I would add from five to eight grains each of chloral and bromide, sweetening the mixture well with simple syrup to cover the taste; whilst in Mr. Hunt's case I would blister the parts where the pain is severe. Thus prescribed, I regard the biniodide as a specific for all forms of meningitis. When occurring in young children, as it so frequently does, during teething, for instance, I have found the mixture act "like a charm." I generally prescribe it one-fourth of the strength given above, and with grain-doses of chloral every two hours. Of scores of cases treated during the last year I have never found it fail to cure. Its action, I argue, is to rapidly absorb that effusion which, to a greater or less extent, must accompany or follow meningeal congestion, and thus to relieve that pressure upon the great nerve centre, which, from the unyielding nature of the cranium, would otherwise cause convulsions. When quiet sleep has been secured with eight or ten doses of the medicine I omit the chloral, but when convulsions are a marked symptom I give two-grain doses of that drug in a separate bottle, with directions to give it every hour or two, or as occasion may require.

I am, Sir, yours faithfully,

Jan. 14th, 1886. C. R. ILLINGWORTH, M.D. Ed.

To the Editor of THE LANCET.

SIR,—Mr. Hunt, in a letter in your issue of the 9th inst., p. 94, asks for suggestions as to treatment in a case under his care. Has galvanism been tried? I remember a girl of about the same age as Mr. Hunt's patient who complained of acute pain in the spine, had a very high temperature, and had apparently quite lost the use of her lower limbs who rapidly recovered under the use of galvanism. Does the total cessation of symptoms at night indicate hysteria?

I am, Sir, yours obediently,

Jan. 21st, 1886. A SURGEON.

FRACTURE OF THE CLAVICLE.

To the Editor of THE LANCET.

SIR,—It is unusual for the surgeon to see the accident the results of which he has to treat. This happened to me recently, whilst engaged in a game of curling at the Glaciarium in this town. One of the players was walking on the ice towards me when his feet slipped from under him and he fell on his back. I could not have said that he fell more upon one shoulder than the other, but no doubt, in the effort to save the back of the head, he did so. He got up and complained about its being a "nasty knock"; but it did not appear that he could have hurt himself much and he continued the game to the end, about an hour afterward. I noticed that he kept the left hand very steady, but thought that some slight muscular injury only had been received, and advised him to foment the limb. Two days afterwards his wife brought him to me, and said that she wished him to be examined as he kept complaining. Upon stripping him I found a fracture of the left clavicle, near the acromial end. As is common in this situation, there was little or no displacement. The double curvature of the bone was very strongly marked, and the muscular development large. These elements no doubt contributed to the result. The artificial ice upon which the fall took place is entirely without elasticity—as unyielding as stone; whereas natural ice with water under it is not so bad to fall upon. We do not often hear of broken bones from falling whilst sliding or skating; nor do I think that fracture of the clavicle often occurs from falling backwards.

I am, Sir, yours faithfully,

Southport, Jan. 19th, 1886. EDWARD DAY MCNICOLL

A WORLD'S SABBATH.

MR. LUIS JACKSON of Chicago proposes the formation of a World's Day of Rest League. He claims, from a practical study of the subject, that human capacity is becoming so great that unless the working men of all denominations take measures to preserve a uniform day of rest, they may lose it altogether. He desires the League to be untrammelled by any question of particular belief, simply advocating that which he believes was the original and humane intent in Mosaism—namely, the guaranteeing to labour a day of rest. He has already proposed to his Jewish brethren that at a convention of representative Jews from all parts of the world, to be held at Paris in the year 1900, the Jewish Sabbath be transferred to the national day of rest by authoritative edict. He fully believes that when this measure is considered by his co-religionists they will make the sacrifice of transferring their sabbath, thus recording on the imperishable tablet of chronology the benevolent and influential action of an ancient church, still vigorous in the cause of civilisation. The movement has obvious bearings on the physical and mental well-being of the human race.

Fairplay.—A is not legally bound not to practise, there being no contract; but practising in a suburb two miles distant would make his situation often very delicate and difficult with reference to B, unless he can get B's hearty consent. With this, and a friendly and honourable disposition on both sides, no great harm need be done to either.

Messrs. Leonard and Co. (New York).—We cannot exchange.

"FRIENDLY SOCIETIES' MEDICAL INSTITUTIONS."

To the Editor of THE LANCET.

SIR,—It was my lot to be in one of the above. Thinking it consisted only of poor men, and judging from the pay that the work would be light, one went in with the idea of studying each case well and doing all that lay in one's power to make it more prosperous and effective as a beneficial aid. That was the idea before going in. The opinion was soon altered by facts, as, instead of working men alone, many of the members were in a good position, above that of a member of a friendly society at least, above the position of obtaining medical advice at a rate that is a tax on the goodwill and energies of medical men and only intended for poor men above the position of those applying to the parish. Two members were town councillors. One member walked into the sitting-room one evening, without the ordinary civility of a maid-servant, and demanded attention to his case. Another time a lady answered the private door to the knock of a member; the member stepped back, stared at her, and asked in a most insulting manner who she was, and this being reported to the committee, was passed by as of no consequence. It would fill a volume to enumerate the outrages committed on common sense and civility at that place. No member ever seemed to grasp the idea that work was being done at the smallest cost by medical officers, who, in performing it, lost caste, heart, and interest in the profession. Instead of a feeling of gratitude and a desire to lessen worry and lighten the work, which, especially under such circumstances, should be the spirit, the reverse was the case, and if objection was raised to an insult, you were immediately reminded that you were paid to do the work. A demand would be sent, where only a message or request was needed. Here was seen all the selfishness, ignorance, and silliness of the public unchecked. Mothers, then, the guides and advisers, were dictated to by working men; children came in repeating the mothers' message, who had prescribed for herself; and in cases where a bottle of medicine and careful directions were all that was required, the advice was thrown to the winds and the contents of 100 or more bottles readily and needlessly taken. The waste of drugs was disgusting; sufficient would be given to last for four or five days, and the next night the bottle was returned for refilling.

Do the members of these places ever think that by the degrading treatment they subject their doctors to, and the poor pay they give them, they are really sowing a bad harvest for themselves? A man's mind is inhibited under such circumstances; his interest lags; he does not put forward determination, energy, or perseverance, and bring his faculties to bear on the cases before him. There is no hope of reward. They really gain nothing by harassing the medical profession with cheap practice, which soon loses its value; many cases are lost that can be saved, but the public are more to blame than the profession, for a doctor is but a human being, and needs rest and recreation to bring his faculties to be of use in working out cases. A man of inferior mind thrives in a social atmosphere, where he is free from insult, worry, degrading circumstances, and morbid surroundings in general, will be more useful than one suffering and labouring under such disadvantages. On having this appointment and going into private practice the benefit of the change was felt at once. Now there was something like being rewarded for work, and interest in the profession encouraged and stimulated. Cases were studied instead of being slurred, hastily prescribed, and the respect shown to one's opinion raised the mind from a drowsy condition, and gave freedom to the judgment. There are, however, difficulties. In these institutions the committee take all the money from the medical officers and give the latter only a portion. In this place the committee must have come to £900 a year, but only £300 was given to the doctors, about £200 to the senior and £100 to the junior. The medical officers should receive all and pay the expenses themselves. It is something to see members swallowing a camel and straining at a gnat by allowing their medical officers to be treated thus, which diminishes the general value of their services, and making a great stir about any little grievance, or fancied grievance, respecting the treatment of a case.

The great alteration required in the club system is for members only to pay—say, 2s. 6d. per member per annum, or some such sum as may be thought fair, and pay a reduced sum for each bottle of medicine and visit. This will do a great amount of good by putting a check on members sending for every trifling thing at all hours. Night visits will of course be more than day. The doctor will not be so annoyed and worried; less waste of medicine will take place; the member will feel more independent, more respect will be felt for him, and, consequently, a better feeling will exist. There will be greater inducement to attend to cases as people under this system will not trifle so readily with medical attendance. At the same time, an effort should be made to allow only artisans, labourers, and such like, to be members of a club, as at the best the remuneration is a tax on the profession.—Yours faithfully,

Jan. 18th, 1886. FAIRPLAY.

"WAKES AND THE SPREAD OF SMALL-POX."

To the Editor of THE LANCET.

SIR,—In reply to Dr. Whitelegge, I must explain that the conviction alluded to in my letter published in THE LANCET of Jan. 16th was not for holding a wake, but for exposing a child suffering from small-pox by removing it from home to another house after having been duly warned of the nature of the disease and that the child ought to be sent to the hospital. It was mentioned as an aggravation of the offence that a wake had been held upon the body of another child, also deceased from small-pox, and that neither child had been vaccinated. Dr. Whitelegge is correct as to the circumstances necessary to ensure a conviction; but I may remind him that under Section 142 of the Public Health Act the dead body of any person who has died of an infectious disease may be removed, and a wake may be thus prevented. Such has been frequently done in Liverpool. The wake is not only a drunken carousal, but also a means whereby a sufficient sum is often, if not always, raised to pay all the funeral expenses; hence the artful devices adopted to prevent the sanitary authorities hearing of the proposed intention to hold a wake, and the difficulty of suppressing the practice.

I am, Sir, yours faithfully,

Jan. 26th, 1886. YOUR LIVERPOOL CORRESPONDENT.

ROMAN CATHOLICS AND INTEMPERANCE.

IT appears that no church can boast of being absolutely free from the vice of drunkenness in its members. No one can refuse a meed of praise to Cardinal Manning for his untiring labours and highly consistent example in the cause of temperance. Some of his speeches have been singularly earnest and powerful. His last utterance on this subject was in favour of a Home of Rest for Roman Catholic inebriates at 41, St. Julian's-road, Kilburn, the first of the kind in the Catholic body. He bore warm and well-merited testimony to the zeal of members of other churches in this cause, and enforced his argument by quoting the calculation that from 60,000 to 120,000 persons in England died annually directly or indirectly from intemperance.

"THE RATIONAL METHOD OF TREATMENT OF HYDROPHOBIA."

To the Editor of THE LANCET.

SIR,—May I be allowed to say a few words about Dr. G. C. Roy's suggestion regarding the subcutaneous injection of diluted cobra poison in cases of hydrophobia, as published in THE LANCET of the 9th inst. Dr. Roy calls it a new and startling suggestion; but some years ago similar experiments were made in Germany, France, and Italy on lower animals. I am not in a position to say if these experiments were made with the poison of the cobra or some other venomous snake; but, so far as we know, there is no difference in the *modus operandi* of the different snake poisons. Until Dr. Roy can show any defects in the above experiments of continental medical men, or any difference in the poisons from different species of venomous snakes, it will be useless to try them again. Perhaps Dr. Roy was not aware of these experiments, or he would have alluded to the same. While admiring the highly scientific way of reasoning out the rational mode of treatment as discussed in his article, I must ask Dr. Roy to find out another specific antidote for rabies, by the same thoughtful study of the physiological actions of different poisons which characterises his last article.

I am, Sir, your obedient servant,

Ealing, Jan. 21st, 1886. N. P. SINHA, M.R.C.P. Lond.

THE ALBO-CARBON LIGHT.

To the Editor of THE LANCET.

SIR,—In my reply in your last issue to Mr. Walters' inquiries regarding the effects of burning albo-carbon, I omitted to state that I was careful to remove the deposit of anhydrous sulphate of copper, which collects in the form of an impalpable powder on the surface of the plate above the burner. Should the above precaution be neglected, I can readily imagine that irritation of the air passages might be caused by the powder being suspended in the atmosphere.

I am, Sir, yours obediently.

Clifton, January 27th, 1886. G. S. THOMSON, M.D.

"LYE-TEA."

A VERY large quantity of what is known as lye-tea has, it appears, recently been sold in the market. It is a spurious tea, and calculated to do immense injury to those who, under the mistaken idea that cheapness and quality are synonymous, consume it. The tea trade itself could easily put a stop to the importation of this poison by simply refusing to look at it; but in the absence of such a happy state of things it ought to be made law that all tea not passed shall be immediately destroyed. As matters now stand, importers of this stuff know that they cannot make a very ruinous loss. If they succeed in placing it on the market and it is passed, well and good; if not, the worst that can happen is that it is has to be transhipped to the Continent at a merely nominal loss. Until such action as we have indicated the necessity for be taken, it is to be hoped that the Custom-house inspectors will by vigorous action check the importation of a compound, the selling of which, either wholesale or retail, ought to be made penal.

Dr. W. W. Skinner.—We are unable at present to entertain the proposal.

Dr. James Oliver's paper will appear in an early number.

"NOISELESS COAL FIRES."

To the Editor of THE LANCET.

SIR,—In an annotation on the above subject in your issue of the 16th inst. (page 125) no mention is made of what is of much importance in a sick-room—the prevention of sound from coals and cinders falling from the fireplace. For many years past I have advised, in ambulance lectures (second or "nursing" course) that, besides wrapping fresh coals in pieces of newspaper (not brown paper), a thick layer of fine ashes should be allowed to remain under the fireplace. Most people dislike the appearance of a dirty hearth; but easily-disturbed patients much appreciate the difference between a noisy and a noiseless fire—a reason why I prefer a gas and asbestos fire in a sick-room. For sick-room purposes the coal should not be of a bituminous, gassy, or flaring kind.

I am, Sir, yours obediently,

Jan. 20th, 1886. S. H.

ALBUMINOMETRY.

To the Editor of THE LANCET.

SIR,—Referring to Mr. Blomfield's description of Esbach's method of albuminometry, in your last issue, p. 153, I am sure most of us recognise the advantage of his plan; there is only one drawback—viz., a special apparatus is required. I have been in the habit of testing quantitatively for albumen in the following manner, with results, I believe, quite as accurate as those obtainable by Dr. Esbach's plan; every consulting-room contains the necessary apparatus. I first measure out a drachm of the urine, test for albumen, taking, of course, the usual precautions, and pour back into the drachm-measuring glass; allow to settle for twelve hours, and then read off the amount of precipitate; say, it is up to the five-minim mark, then I note, "Albumen one-twelfth." The actual amount passed per twenty-four hours can thus be found either by weight or bulk.

I am, Sir, yours truly,

Clifton, Jan. 25th, 1886. ARTHUR PRING, B.A.Camb.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir William Mac Cormac, London; Mr. Macnamara, London; Mr. Godlee; Mr. A. Clark, Bath; Dr. Leibowitz, Vienna; Dr. Thomson, Clifton; Mr. R. Introductory Lecture

TO THE COURSE OF

CLINICAL THERAPEUTICS.

Delivered at King's College Hospital.

BY I. BURNEY YEO, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL, AND PROFESSOR OF CLINICAL THERAPEUTICS IN KING'S COLLEGE.

GENTLEMEN,—In addressing you for the first time as Professor of Clinical Therapeutics in this College, my first duty is to thank the Council of the College for the honour they have done me in entrusting to me the duties and responsibilities of this new chair. It will be expected of me that I should on this occasion set before you some account of the objects and practical ends which should be aimed at in the course of instruction which may legitimately fall under the designation of Clinical Therapeutics.

Nothing, perhaps, would surprise an intelligent lay inquirer into our system of medical education more than to hear of the great number of subjects to which the student of medicine is compelled to give a large amount of attention, and to learn at the same time that the subject of therapeutics—the subject which is especially concerned with the practical application of all these other subjects, for which alone they are taught—has been, for most practical purposes, omitted altogether. It would, I imagine, be extremely difficult to offer any satisfactory reason why the subject of therapeutics—the subject of the treatment of disease—should have been so long allowed to occupy such a very subordinate and almost effaced position in our system of medical education. It is still more difficult to understand why that curious fiction should be persistently and authoritatively maintained, that it is possible to teach therapeutics as well as materia medica and pharmaceutical chemistry in the short summer course devoted to these subjects. I observe that in eight out of eleven London medical schools a course of from thirty to thirty-three lectures is all that is available for the teaching of those subjects; and it is expected that in this short summer course the natural history and the physical and chemical properties and compositions of about 250 vegetable substances, of over 140 mineral and 25 animal substances, as well as nearly 500 of their compounds, shall be taught and learnt, and that the student shall acquire the ability to recognise, identify, and describe them. In addition to all this, it is further pretended that in this short course the physiological action, uses, doses, and applications of this enormous number of remedies in the various diseases in which they may be employed is examined and taught. It may probably be urged that the subject of therapeutics falls largely under the head of the Practice of Medicine, and so in a measure it does; but every professor of the theory and practice of medicine will tell you that he finds it impossible to discuss fully the treatment of disease in the limited time allotted to him for dealing with the vast number of other important subjects which he has to consider. It is thus clear that a vast field of inquiry, a vast field of practical study, of the very highest importance to our art, has hitherto received little or no systematic recognition or consideration in our system of medical education. In undertaking the task of supplying in some measure this defect, I must ask you to extend to me that indulgence of which a more competent exponent than I am might well feel in need in attempting so new and possibly so difficult a work.

And now allow me to explain to you what I understand to be the meaning of "clinical therapeutics." By clinical therapeutics I understand the rational examination and discussion of all the various means and methods that can be applied to the amelioration and cure of disease. Clinical therapeutics is not the study of therapeutics in the physiological laboratory; it is the study of therapeutics side by side with disease. It is not the work of the experimental physiologist; it is the work of the practical physician; it is the supreme test of all therapeutic work. I am not in the slightest degree undervaluing the labours of the experimental physiologist when I say that, so far as practical medicine is concerned, his results are but the raw material which clinical therapeutics has to sift, examine, select, accept or reject. And it is unwise to overlook the fact that the complexity of the conditions which exist in many forms of disease, and the impossibility of always, or even commonly, ascertaining all of them, tend to render the results obtained under the far more simple conditions of physiological experiment, and the reasonings founded on them, occasionally more embarrassing than helpful. It has been objected to the "clinical" study of therapeutics that it is faulty as a method, and not calculated to lead to precise "scientific" conclusions. This criticism is itself most open to be criticised. In the first place, I would say that no real and lasting gain to knowledge comes from the attempt to be more precise than the subject matter of our inquiry admits of. To affect to be absolutely precise in a study in which precision is not possible is only, in the end, to confuse and mislead. In the doctrine of the treatment of disease, in many of its forms the *à peu près*, the "more or less," alone is accurate and true. Of what use is it to lay down precise laws as to the action, for instance, of opium and its derivatives in disease, which may be contradicted in the very first case in which you administer that drug? It is not a law, and it may be wholly without precision, but it is nevertheless an important fact in therapeutics, that a sixth of a grain of morphine will in some persons produce alarming syncope and nausea, while three times that quantity in another person will produce a sense of extreme comfort and enjoyment. This is a clinical fact in therapeutics; it cannot be called a "precise scientific" conclusion; but it is only one striking instance of a vast number of like facts that could only have been discovered by this method. It may sound somewhat paradoxical when I say that if the clinical *method* of studying therapeutics is faulty, it is because it has not been sufficiently *methodised*. Every accomplished and intelligent physician and medical practitioner possesses a series of therapeutic facts and observations, many of which he has acquired for himself, many he owes to a sort of unwritten tradition, and these for the most part he keeps to himself. I intentionally state it as a reproach, that the physicians in the largest practices rarely communicate anything to the profession of their modes of treatment. They will read elaborate papers and lectures on more or less disputed pathological doctrines, but as to the therapeutic methods they practise, as to the therapeutic observations they have made in the course of their vast experience, they are, for the most part, as silent as their own door-plates. The clinical method in the study of therapeutics would prove far more useful and fruitful than it is if the best and most experienced clinical observers were to make some attempt to systematise their conclusions, and freely to compare and test one another's observations. Moreover, a fact observed clinically in therapeutics, I mean carefully observed and tested by several observers independently, has not only its own immediate practical value, which may be enormous in its direct and indirect consequences, but it may also be most important and useful in affording to the experimental pharmacologist and physiologist most pregnant hints as to the course his investigations should take. Let me instance to you a few out of many facts in our knowledge of the treatment of disease which have been arrived at by the clinical method, and to which physiological experiments could hardly have conducted us: although the experiments of pharmacologists may subsequently throw important light on the mode of action of some of those remedies.

It has seemed to me that one of the most remarkable gains in the treatment of disease in recent years has been the employment of large doses of iodide of potassium in the treatment of internal aneurysms. In common with many physicians, I have seen more satisfactory results follow this mode of treatment than any other. Yet when first I began the use of iodide of potassium in the treatment of internal aneurysm my results were disappointing and my belief in the remedy slight. I found the same to be the case with some eminent physicians and surgeons whom I met in consultation. But in the year 1877, on the occasion of the meeting of the British Medical Association at Manchester, I was fortunate enough to see in the infirmary of that city a number of cases of thoracic aneurysm which had been collected together by Dr. Simpson for the purpose of showing the members of the Association the value of the iodide of potassium treatment in such cases. It was certainly a remarkable

Digitized by Google

series of cases, and the results were excellent; and it was then I found that whereas in London I and others who had tried this treatment had been content with giving five-grain doses three times a day, Dr. Simpson had given twenty, thirty, and forty grain doses instead. Now, as soon as I began using these large doses of iodide of potassium in the treatment of internal aneurysm I realised its great remedial value, and I have had the happiness of seeing most admirable results follow the prolonged administration of these large doses. It is only by the *clinical* method of observation that we could have established a fact of this kind. Many suggestions were made as to the mode of action of the iodide in these cases. The first to be put forward was that the cases in which the iodide proved of value were syphilitic cases, and that its beneficial effects were due to its anti-syphilitic properties. But this view, as Dr. Balfour has pointed out, would only make its action more mysterious. Another suggestion was that the iodide increased the coagulability of the blood, and this it may possibly do; but post-mortem examinations seem to show that the process of cure is obtained chiefly by "some peculiar action on the fibrous tissue," causing thickening and contraction of the walls of the sac. It had been noticed clinically [1] that in some cases, under the influence of the iodide, the pulsations in the aneurysmal sac and throughout the arterial system were much diminished in force, and this was referred to a reduction in the intra-arterial blood-pressure brought about by the action of the drug. Physiological experiments appear to confirm this view, and to show "that one of the chief actions of iodide of potassium is to lower blood-tension uniformly throughout the body by dilating the arterioles," and at the same time diminishing the force of the heart's action.

Next, let me call your attention to the therapeutic uses and value of arsenic as established by the clinical method. I need scarcely mention its well-known influence in the cure of certain affections of the skin; it is rather to other uses of this drug, such as Dr. Wilks and Dr. Clifford Albutt have borne witness to, that I would call your attention. Dr. Wilks, whose skill, caution, and insight as a clinical observer will be universally admitted, has satisfied himself by clinical observation solely that arsenic has the power of preventing attacks of gout and of angina pectoris. He is impressed, too, with its remarkable value in relieving some forms of asthma, in certain neuralgias, in cases of anæmia and impaired nutrition, and especially in certain cases of general cachexia of doubtful origin.[2] Dr. Clifford Allbutt has also borne unhesitating testimony to its value in the treatment of many forms of visceral neuralgia. Now these observations, the accuracy of which has never been seriously called in question, are due entirely to the clinical method. Let us see what amount of agreement exists amongst experimental pharmacologists as to the action of arsenic. Sklarek considers his experiments to have demonstrated that arsenic impairs sensibility and leaves the motor functions unimpaired; on the other hand, Ringer and Murrell's experiments, it is maintained, prove that Sklarek's conclusions are incorrect, and that motor paralysis precedes the loss of sensibility.[3] Then it has been established, or at any rate authoritatively stated, that the effects of arsenic on the circulation are not the same in warm- and cold-blooded animals; so that inferences from observations made on the vaso-motor system of cold-blooded animals cannot be applied to the case of mammalian animals, and therefore to human beings. The statement of Saikowsky, that arsenic causes fatty degeneration of the liver, kidneys, heart, and other organs, would scarcely have led us to any great enterprise in its application to the cure of disease, nor does it throw any light on the well-known fact that the arsenic-eaters of Southern Austria and Styria, who take enormous quantities, "improve in bodily condition, gain in breathing power, and become stronger and more pugnacious and also more salacious."[4] Moreover, it has been stated as the result of experimental investigations that arsenic arrests the formation of glycogen in the liver, and by one observer that it lessens the excretion of urea (C. Schmidt), and by another (Prof. Gäthgens) that it causes an actual increase of the amount of urea excreted. So I think we may fairly say, with regard to the therapeutic uses of arsenic, that we have acquired more precise knowledge from our clinical method than we could have derived from the results of pharmacological experiments.

Another fact in therapeutics which could only have been derived from clinical observation is the much greater efficacy which aconite possesses in arresting or modifying the febrile process in children and young people than in persons of mature age. It is quite remarkable how a few doses of aconitine will rapidly subdue the febrile attacks which are commonly associated with local inflammation or other disturbances of health in children and young people, but if you look for the same results in persons of riper years you will be constantly disappointed. Now, here we see an opportunity for a precise clinical investigation, in which, however, a considerable number of observers would have to be associated—viz., to ascertain the exact relation of the activity of aconite to the age of the patient.

No other method could have taught us the extreme value of the topical application of opium in the relief of local inflammations, especially when traumatic, than the clinical method. And I may here express my surprise at the comparatively little use that is made of this method of relieving the pain and distress of local inflammations by practitioners in general.

The value and applicability of the different forms of counter-irritation, and the appropriateness of one form rather than another in various diseases, are wholly the outcome of the clinical method; and this, again, is a subject which might be brought to a great degree of precision by the combined observations of a considerable number of practitioners.

(To be concluded.)

Introductory Lecture

TO THE COURSE OF

OPHTHALMOLOGY.

Delivered at University College, Liverpool.

BY EDGAR A. BROWNE,

SURGEON TO THE EYE AND EAR INFIRMARY, AND LECTURER ON OPHTHALMOLOGY IN THE COLLEGE.

GENTLEMEN,—In entering on a new study, as in visiting a new place, it is well to begin with a plan. Think for a moment how two travellers in a strange town may learn much or little according as they proceed in an orderly method or in a tourist's hurry-skurry to make their observations. One, it may be, is provided with a handbook and a map, and sits down for an hour or so after his arrival, learns the names and directions of the main streets, the situation of the principal buildings, the meanderings of the river and number of its bridges, and perhaps secures the services of an intelligent guide, who takes him over the ground. In a short space of time he acquires a fair knowledge of his bearings, glances at the sights, and selects for more leisurely examination those which appeal to his taste. However limited his time may be, he makes his exploration on some kind of system, sees what he desires to see, and neglects the things that do not interest him. The other scarcely allows himself time to secure rooms; hurries out into the streets, bent on seeing pictures, statues, and ancient buildings; asks his way of the first bystander, who misunderstands him first and misdirects him afterwards; becomes involved in a labyrinth of side-streets, and after an infinity of trouble arrives, footsore, weary, dirty, and ill-tempered, at, let us say, the barracks in a remote suburb, and has no resource but to charter a cab to take him back to his hotel. Think of the different results of travel on these two men: the one returns home with pleasant memories and some useful knowledge, the other with a recollection of innumerable worries and a phantasmagoric jumble of erroneous impressions. So is it exactly with explorers in the vast territories of modern knowledge. As we enter into fresh tracts we require fresh guidance, multitudinous facts surround us on every side, confusing us by their number and bewildering us by their complexity. The confusion is mainly due to our seeing facts all alike, without being able to estimate their varying degrees of importance. We have no mental perspective, and cannot relegate facts to

Digitized by Google

their relative positions—as a child, who has not yet learned to estimate the value of his visual impressions, has no idea of the distance of objects, and deems he may make a plaything of the moon. It is my duty to help you over these early difficulties. I shall essay to supply you with a plan; to direct your attention to the facts of greatest importance; to aid you in avoiding the distracting influence of those of less consequence; to show you the relationship of these facts one to another, so that you can afterwards, if you choose, add detail to detail till you have mastered as much of the subject as may be necessary for your purpose. In a word, I shall tell you what you ought to learn, and shall arrange and describe for you the principal objects you will be required to study. I shall give you, as it were, a bird's-eye view of the subject, and shall endeavour to make you understand which are the chief landmarks, and what renders them important. Then having, so far as we are able, gained an intelligent idea of our subject, I will, if you permit me, act as the guide I have already referred to, and aid you in your application of this knowledge, and in the simplification of the bewildering mass of material that is afforded by the practice at the Eye and Ear Infirmary. You will gain comparatively little by your attendance at the hospital if you do not first of all acquire some idea of what you are going to see, and a moderately definite notion of how you should methodise your observation.

Let us begin at the beginning. Why has ophthalmic surgery developed into a distinct and special branch? How is the eye differentiated from all other organs we are called upon to treat? In this manner: The eye is an optical instrument; its function is to deal with light, to refract rays, to measure the extent of illuminated areæ, to estimate the velocity of luminous undulations, and to transform the vibrations of the luminiferous ether into those coarser vibrations which constitute nervous impressions. In every pathological process that takes place, in every surgical procedure that we undertake, there is involved the destruction or the preservation of the optical integrity of the eyeball. If that optical integrity be not preserved our labour is in vain. So far as the mere optical mechanism of the eye is concerned, it may be said to be simply a camera obscura, differing only in detail from the instrument used by photographers. You are all acquainted with its structure. In front is the pellucid curved surface of the cornea for the refraction of rays of light to a focus on the retina; then the iris, with its mobile aperture, the pupil, which acts as a diaphragm according to the varying amount of light; behind this the crystalline lens, with a convexity that can be altered when a change of focus is required. In front of the lens is the aqueous humour; behind it the vitreous body: both serving, by means of their surfaces and their indices of refraction, to render the eye as nearly achromatic as is needful. These structures fulfil their optical purposes exactly as if they were constructed of so many different kinds of glass. But they are not simply optical structures, as they would be if they were constructed of different kinds of glass; they are at the same time vital structures. They subserve two purposes. They are essential to the optical functions of the eyeball, it is true; but they are equally essential to the vital economy of the whole organ, and are subjected to the same physiological and pathological laws as the other tissues of the body.

Let me illustrate these propositions. The cornea is a transparent, curved, refractive surface—a lens. Optically, there is an end of the matter. Structurally, it is, as you know, a continuation of the sclerotic, having its connective tissue modified so as to render it transparent. In furtherance of that end it is deprived of its bloodvessels, and its nutrition is maintained by means of numerous lacunæ which freely anastomose one with another by means of canaliculi. Through these channels lymph passes freely, and in inflammation migrating cells in great numbers have been observed thronging the passages. Given a membrane of this character, largely constructed of connective tissue, freely supplied with lymph, but at the same time wholly extra-vascular, and moreover—except for the brief protection afforded by the blinking of the eyelids—much exposed to external influences, you would be inclined to predicate that it would be likely to inflame, that its passages were likely to become gorged and infiltrated with leucocytes, that it would form a favourable soil for septic infection, and would on the least interruption to its nutrition easily ulcerate. This is so; but unfortunately every one of these pathological processes impairs the transparency of the medium. A comparatively slight and temporary infiltration of the cornea will permanently alter the refractive index of its layers and produce a permanent impairment of sight. An ulceration of the anterior surface may give rise to so little inconvenience that it is not noticed till the beginning of cicatrisation. The ulcer itself escapes recognition because it is transparent; but when Nature begins to heal, she heals with the same journey-work that does duty in similar tissues in other parts of the body, and produces a white speck which is visible to the observer and detrimental to accurate vision. Or take the iris. Its primary function of regulating the amount of light admitted into the eye is purely optical, but it is a highly vascular structure, serving a distinct purpose by secreting lymph for the nutrition of the lens and vitreous. Clinically, it may be said to conduct itself like a serous membrane—just as one man exposed to cold may have pleuritis, so another exposed to cold may have iritis. When the iris inflames, disturbance of its surface secretion occurs, and lymph of an adhesive character is exuded. The edge of the pupil lies, as you are aware, in contact with the anterior capsule of the lens. After the inflammation has subsided, it is frequently found that adhesions have been formed and the margin of the pupil is bound down to the lens capsule. The first effect of this is to destroy its power of expansion and contraction. The pupil has become fixed and its optical function impaired. But a further and more serious consequence may follow. Normally, the lymph secreted by the ciliary body and the posterior surface of the iris should pass from the posterior chamber, between the lens and the margin of the pupil, into the anterior chamber, and thence into the canal of Schlemm, and so into the general circulation. But when the communication is obstructed, the pent-up lymph, unable to escape, presses the iris forwards till it will yield no further, and then, increasing the pressure of the whole vitreous chamber, thrusts the surface of the optic nerve backwards through the sclerotic opening and causes the fibres to atrophy. Blindness of course results, if relief be not given by a timely iridectomy.

In both these instances you will perceive the optical function and the nutritional character of the structure are both involved, that they are both closely connected, and the one reacts upon the other. It is this dual character of the tissues of the eyeball that differentiates it from other organs, and ophthalmic surgery differs from general surgery in involving a constant reference to optical considerations.
